(THE) BUILDING NEWS

AND ENGINEERING JOURNAL.

V 41 (1881, July-Dec)

BEAUTY AND EXPRESSION.

THE greatest change, perhaps, that has passed over English architecture within the last dozen years is this: that it has given up, in great part, the search for beauty, and has entered, instead, on a search for expression. For a century and more it had copied all the finest styles of the world one after another; and the reason it assigned for copying them was, in the main, the perfection of their form. To find what was most beautiful, and to repeat it everywhere, was the universal desire. It was a foolish desire, but one that still lingers amongst the shallow, the plausible, and the imperfectly educated. It was foolish for many reasons, of which these are a few:—Suppose you have found the most beautiful style—say the Greek—it may well happen that you cannot really repeat it, because you have not the materials to repeat it in. Instead of white marble, you have nothing better than sandstone and limestone, brick and stucco. You cannot repeat it, again, because you have not the sculptors who give life to it—detail. Instead of Phidias and Praxiteles you have the ambitious stonemason who calls himself a carver, and the monumental artists of the New-road. And if you had the materials and the men, you have not the climate and the sky. Instead of sunshine you have fog; instead of pure air you have smoke; instead of the golden tints laid on by time you have the dirt and filth ingrained by a London atmosphere. And further, suppose all these, and twenty other reasons, done away with: suppose it possible to copy the Parthenon and the Erechtheum everywhere, and to see the copies as perfectly as ever the originals were seen, would it even then be wise to put the highest type of beauty everywhere? A crimson sunset is very fine; but who would care to look at it if it happened every night? And suppose, yet further, that to us, as it really may be to the planets around certain coloured stars, crimson were the common light of day; does anyone imagine for a moment that we should think the world more beautiful than it now is? If everything were crimson, we should probably not know that crimson existed: we only recognise it by contrast with things that are not crimson. So it is with beauty. If the highest type of beauty could be everywhere, we should never be conscious of beauty at all. The people who talk of aiming at it everywhere are like a man who should look at the Alps and say, "How magnificent

those mountain-summits are: what a glorious world this would be if it could all be raised to that level!"

Constituted as men are, it is essential to their enjoyment of the highest beauty that it should be somewhat rare and exceptional. If flowers were as persistent as leaves, we should admire them no more than leaves; it is the winter that makes it possible for us to appreciate the spring. Yet the idea that was long held up to modern architects was the ideal of a world all flowers and no leaves; all crimson sunsets and no grey skies; all mountain peaks and no valleys between them; we were to be always on the highest level, and to think nothing in old work worth our imitation which was not on the highest level too. Unlike Homer, we were never to nod. Whether we were building a church, a shop, a theatre, or a dwelling-house, the sublimest models were always before us. Details from the finest Greek temples, and afterwards from the noblest Gothic churches, were considered none too good for the meanest positions. This was high civilisation, this was true refinement, thus to skim the cream off bygone art, and to reject all the rest of it. The architectural world, in fact, tried to live on cream and nothing else, and has ended by finding the diet rather sickening and very unwholesome. In other words, after trying to use the highest types of beauty everywhere, after putting Greek-temple details into London shop-fronts, and Gothic-church details into London houses, it has simply nauseated itself with both Greek and Gothic. Its search for beauty, just at present, is over, and, by way of change, it is devoting itself to a style in which beauty of detail is certainly at the lowest. In the ugliest of styles, however, as in the ugliest of faces, there may be room for expression, and expression seems to be what is aimed at, sometimes with a good deal of success by the abler designers who have lately taken up 16th- and 17th-century types of building.

To describe in words the expression of any particular design is often a very difficult thing, and yet the design may affect the mind in a perfectly definite and characteristic way. The fact is there are an infinity of shades of feeling for which we have no words, although certain architectural compositions, like certain musical ones, may each produce its own shade of feeling with something like certainty. The compositions which do this live in the memory as

having a character, an individuality, a distinctness of their own. We may like them or dislike them, but they act upon us like living powers. They differ from each other and from the things around them; and instead of the dead-level, all-alike world of the high-art-everywhere school, they give us a world of ups and downs, of attractions and repulsions, of better and worse—the sort of world which interests men, and will interest them, until they become something very different from what they ever have been yet. This kind of art-world, however, is no novelty. It was the art-world of every great epoch—nay, of every living style—with one difference. Just now men, tired of pursuing nothing but beauty, have, for the moment, renounced beauty; but, then, beauty and expression were followed together. The highest beauty was kept for the highest things; humbler types of beauty fitly found a place in humbler subjects, while character, individuality, expression, were to be seen in all things, from the noblest to the meanest. To-day is a day of penance for past mistakes; but the time will come when beauty, in its own place, and expression in every place, will once more be united. Till then, we are sure to have two classes of people who will find it difficult to tolerate each other: the class who have given up beauty for expression, and the class who do not like expression when they see it. They will quarrel more fiercely over other arts than over ours; but even architecture, as our readers may observe, comes in now and then for its share in the dispute.

CONTRACT CERTIFICATES.

QUESTIONS are continually arising as to the duties and liabilities of architects in certifying or refusing to certify for amounts claimed by builders under contract, and the correspondence in our own pages from time to time has borne witness to a certain misunderstanding between builders and architects as to the power of the latter in granting or withholding certificates. It is a very common thing to hear of a builder being aggrieved by the architect refusing or withholding a certificate, and attempts are often made by the builder to obtain, through a court of law, the money alleged to be due, or a measure-and-value price; but such conduct on the part of the builder proceeds from a very imperfect view of his obligations under the contract.

When it is expressly stipulated, as it is in most contracts between builder and employer, that payment shall be made after the architect has certified such an amount to be due, the certificate is a "condition precedent" to the establishment of a claim; that is to say, in plain English, the absence of the certificate is an answer to an action at law, and prevents the contractor recovering, as it was stipulated no payment should be made without one. The case of "*Morgan v. Birnie*" is the leading decision which has established this point, and in another case ("*Milner v. Field*") it has been held that even if the certificate is withheld by fraud, the builder cannot recover if it is pleaded a certificate has not been given, though the builder can bring a special action for damages in such a contingency. Though this rule and its confirmation by the decisions we have referred to are in the abstract perfectly just, it would not be difficult to imagine a case in which the builder failed to obtain a fair consideration from the architect, where some slight provocation or trivial matter, having nothing whatever to do with the granting of a particular certificate, was made an excuse for refusing to give the contractor what he may be fairly entitled to. Differences of this kind often arise, as our practical readers will know. A contractor may have a claim for "extras" which has become a question of dispute between him and the architect, and the latter, by refusing to give a final certificate for the balance, exercises a kind of coercion prejudicial to the contractor's interest; or, the certificate is given for an amount less than the net balance payable in respect of works executed, and thus in effect, it compels the builder—if a man of small means—to relax his efforts to obtain the money to which he may be honestly entitled to. We do not entertain so low an estimate of the profession as to believe such a course is frequently taken, though we know undue pressure is often put on the builder in this way, and a kind of extortion is exercised which places the architect rather in the position of a despot than a judge. The builder has, however, his remedy in the event of his being able to establish by evidence, negligence, misconduct, or fraud on the part of the architect. If he can show that the certificate has been withheld by any of these causes he is entitled to the Court's protection. If he can prove the architect has fraudulently withheld a certificate he has a remedy against the architect, as in the case of "*Ludbrooke v. Barrett*," where the judgment showed that when the certificate is withheld fraudulently and in collusion with the employer, the builder can sue the architect for damages. In another instance ("*Batterbury v. Vyse*") it was shown that the architect had approved the work, but that he refused to certify in consequence of collusion with and by procurement of the defendant, and the Court held this was a good cause for action against the employer. In another decision ("*Pawley v. Turnbull*"), certificates had not been fairly made, and the evidence showed that the architect "acted improperly and unfairly in the exercise of the powers conferred upon him by the contract," and the plaintiff recovered from the defendant the full contract price and a sum for extra work. In like manner, if the certificates showed more money due to the contractor than he was fairly entitled to, the employer would be able to bring an action against the architect. The last decision ought to be a governing principle. If an architect plainly violates his duty, and has shown unfairness in the discharge of that duty, even though no case of actual fraud have been established, the rule of equity we have stated may be taken to be that which will be followed in the Courts.

As we have seen also, the effect of a certificate is equally binding on the employer as well as the builder, as was clearly

proved in the case of "*Laidlaw v. The Hastings Pier Company*."

A very important question connected with the subject is the position the architect or engineer occupies under ordinary conditions of contract. Recent decisions make it doubtful what exactly is the law on the point. We may refer here to the very important case of "*Stevenson v. Watson*," the facts of which are simply these. The defendant, the architect, supplied plans, specifications, and bills of quantities for a public hall, and the builder, the plaintiff, undertook to build the same, under the ordinary conditions of contract, the architect having the power to order any additions or deductions, the amounts of which were to be ascertained by him in the same manner as the quantities were measured, and at the same prices. There was another clause in which the contractor and the directors bound themselves to leave all questions or matters of dispute to the architect, whose decision was to be final and binding upon all parties; and the contractor was to be paid on the certificate of the architect. The quantities were found to be deficient in brickwork and stonework, and the builder requested the architect to measure at various times the omissions and additions which were made, but without avail, and the builder had these carefully measured himself and tested by competent surveyors. A claim was made amounting to £1,616 odd, of which £500 or £600 were for errors and deficiency in the quantities and the rest balance on the contract. The architect certified for a balance of only £251 odd, and refused to give any explanation to the plaintiff, or to furnish him with any data upon which this certificate was based. Stevenson then brought the action for £1,364 odd, and the claim alleged the defendant did not use due care and skill in ascertaining the amounts to be paid under the contract, that he refused to ascertain the amount of the additions to and deductions from the contracts, and refused to give any explanation to the contractors or to hear his objections to the certificate. Lord Chief Justice Coleridge, in giving his decision, said the architect was in the position of an arbitrator, and, therefore, not liable for want of care or skill. In brief, it was to the effect that a builder could not bring an action against the architect for not using care and skill in ascertaining the amounts to be paid under a contract which provided that the builder was to be paid on the certificate of the architect, and that all matters of dispute were to be left to his decision. The judge clearly regarded the architect under such conditions as an arbitrator, his functions called for the exercise of judgment, therefore the architect cannot be called upon by one of the parties to reconsider his certificate or to give reasons for it. The allegation that he knowingly or negligently certified for a less sum was not a cause for action, as there was no charge of fraud imputed. The decision is certainly not quite satisfactory, as pointed out by those who have commented on the case,—it certainly sets aside the principle of equity we have just mentioned; while with regard to the quantities, till this case, it was generally assumed the quantity surveyor was responsible for want of correctness in them. Moreover, the Court decided the case with the understanding that there would be an appeal in any event against their decision. The point, however, which most concerns us here, is the conclusion arrived at as to the architect's position. It has been contended, with some show of reason, that the architect is rather in the position of a valuer than an arbitrator; his function is to measure up and price the work as an agent of the builder. In another and still more important appeal ("*Laidlaw v. Hastings Pier Company*"), this question was discussed. In that case it

whether they were conclusive as to the facts ascertained in them, and the opinion of one of the judges was that the engineer in that case was not an arbitrator, but rather an agent of the defendants clothed with certain functions to be exercised in cases provided for by the deed. Differences of opinion arose on the bench. Lord Coleridge concurred in the decision of "*Goodyear v. Mayor of Weymouth*" that the engineer was an absolute judge as to extras and additions; but Mr. Justice Grove pointed out the control exercised by the defendant's in the provision to the effect that the contractors shall not plead any acts, orders, or directions of the engineer unless they shall produce special instructions signed by the engineer and countersigned by the chairman of the company, and that no extra work shall be paid for unless executed under such countersigned instructions. Mr. Justice Quain corroborated this view; and thought that the certificates given from time to time were merely provisional, and not conclusive. They were in fact "progress certificates" to enable the contractor to go on with the work, and not conclusive if the work contained in them was never done. Mr. Justice Archibald thought otherwise: the engineer, he considered, was in the position of a valuer, that he was to decide on extras upon the ground of his own skill and knowledge of those matters.

These references are sufficient to show the differences of opinion, even among lawyers, upon the question of the finality and conclusive power of certificates. The decision of the case of "*Laidlaw v. the Hastings Pier Company*" is pretty well known. The defendants were bound by the final certificate, and we may fairly take this decision as indicating which of the above opinions is deemed law. In another instance, where the architect was to certify the amount to be paid for work and extras, it was held that the certificate that a certain sum was due precluded the employers from raising the question. Again, it has been settled that if the final certificate takes no account of penalties, and advances have been made after the date of completion, it is evidence of the time having been extended, and the penalties cannot be deducted. Progress certificates, or those made from time to time to keep the builder in funds, are no doubt merely provisional, and the architect is not bound by them; but care and skill ought to be exercised in adjusting the amounts which may be advanced with safety in every case. On the whole, it seems pretty clearly established that the architect's certificate under carefully drawn-up contracts is a very binding and conclusive instrument on both parties to a contract, but one, nevertheless, requiring a great deal of discretion on the part of those who grant it.

PARTY-WALLS AND FENCES.

QUESTIONS touching the rights of tenants in respect of fences and party-walls are of such constant occurrence, that it may be useful to refer to a few principles which have been laid down and acted upon in courts of law in relation thereto. Of course, cases which come within the jurisdiction of the Metropolitan Buildings Act are pretty clearly defined by the provisions of that Act; but the law, as there laid down, is of limited operation, and does not apply generally. The rights and liabilities of tenants in common with respect to party fences walls, are subjects of constant litigation and misunderstanding. A and B are separated by a party-wall, and A desires to pull down his portion of the wall; but, in so doing, he disturbs the rights of B. Is A. liable for such disturbance, or has B. any remedy? Or, a party-wall is built at the joint expense of two parties, each contribut-

ing his share of land. One of these parties injures the other's portion of the wall. Is he liable? Another very common instance is the following:—A builder of two houses grants one. Does he, by such grant, give to either party the power to cut the wall in half? Again, how is the ownership of a wall, bank, or hedge to be established between two proprietors? These are a few of the questions which are continually cropping up and requiring solution, and most surveyors have, at various times in their practice, experienced doubts about the liability of vendors or vendees to maintain boundary fences, and the liability to repair between landlord and tenant. In most of the cases we have supposed, some easement has been acquired, or the common user of the wall, bank, or hedge belonging to different owners is *prima facie* evidence of its belonging to the owners of the adjoining lands, as tenants in common. When the extent of land originally belonging to each owner can be ascertained, each party becomes the owner of that portion of the wall or bank which stands upon his own land, and he has a remedy for any injury done to it by his neighbour. It oftener happens that the precise circumstances are not known, or have been forgotten, and, in such case, the presumption of the law is, that a tenancy in common exists, and that the wall or bank belongs to the two proprietors in equal moieties. Thus, if a builder of two houses grants off one, it is reasonably supposed that he grants the whole wall in undivided moieties, and that neither party has a right of cutting the wall in two. If half a party-wall, on the other hand, belongs exclusively to one proprietor, and the other half to another, either owner can pull down the part of wall standing on his own land, although sufficient support may not be left for the adjoining portion; and such a right can only be prevented in circumstances from which a grant of an easement conferring a right of support may be implied. If A. and B. are adjoining owners of premises, and if A. required to form a cellar, he would, according to this principle, be entitled to underpin or disturb the foundation-wall of B.'s house, after giving B. notice of his intention. It would be the duty of B. to insure the safety of his own premises by underpinning the walls to the same depth. In the case of *Trower v. Chadwick*, it was held that the mere circumstance of two walls being in juxtaposition does not give a right of support, nor is a person liable, in pulling down his wall, for not giving notice of his intention to the owner of the adjoining wall. One of the owners in severalty of a party-wall cannot pull it down, however, when there are cross-rights of easement, without being liable for disturbing the rights of the next owner.

As regards the easement of support, from recent decisions, it would appear that special circumstances must be adduced, giving the right of support, as for example, when two walls are built so that the removal of one will cause the injury to the other, and both at one time belonged to the same owner. In such a case, the legal presumption is that the owner, in granting away the house on one side, reserved to himself a right of support for his adjoining house, and, therefore, conferred on his grantee a similar right as an easement. (See *Suffield v. Brown*.) The legal textbooks give little decided information upon the moot point as to what constituted such an easement; mere lapse of time does not always give it, and it appears, from the case of *Solomon v. Vintners' Co.*, that the enjoyment of support must have been open, and as of right. In all instances this right must be founded upon prescription or grant, express or implied. We need not further go into the question, but refer the reader to the case just decided by the House of Lords, and commented upon in our last issue. Fre-

quently, questions arise as to the ownership of a wall, hedge, or bank; in all such cases acts of ownership must be proved. Thus, if a wall separates two properties, and it has been the habit of both to fasten anything to it, or to alter or add to its height in any manner, it may be safely affirmed there is *prima facie* evidence of its being common property. A more important question is, whether a person building has any right to allow his eaves to project over his neighbour's property, so that the rain-water is discharged from his roof upon it? However unfair it may seem, the right of building so as to overhang adjoining property, or of discharging rain-water thereon, may be acquired in the same manner by user; it is, in fact, the old right of *servitus projiciendi*, and other servitudes of a like character may be acquired, by which people often make themselves obnoxious to their neighbours. For example, how often the owner of a house can compel his neighbour to receive all the water from his roof or flat, for which greater provision of pipes has to be made by him. Or we hear of a man's party-wall being made use of to support an erection of some kind. Such rights, of course, must be acquired by prescription. It is often thought that if the dominant owner added to the height, or altered his wall in any manner, the right is destroyed, but it has been ruled otherwise. He can still let his rain-water discharge on the premises of his neighbour, so long, at least, as he does nothing to increase the burden.

The repair of party-walls is another cause of disagreement. A party or fence-wall between two properties becomes ruinous, and one of the tenants in common calls upon co-tenant to aid in the repair; but the law does not imply any obligation on the part of one tenant in common towards the other, and it appears, from cases decided, that a tenant in common cannot maintain an action against another for cutting trees or clipping hedges, nor for pulling down a wall with intent to rebuild it, so long as there is no misuse of the property, or no waste has been committed.

In measuring estates, the boundaries between fields are often the cause of much difference of opinion, as our own pages have shown. The law as to fences is, unfortunately, not very clearly understood, and the custom of surveyors in measuring seems to vary very much in different parts of the country. Thus, in one direction given in a textbook upon land surveying it is stated:—"If the ditch be inside the boundary fence, it usually belongs to the estate, and *vice versa*, although this is not universally the case." As to the breadth of ditch, we are told in some places five links from the hedge posts or roots of the quick are allowed, but this varies as much as ten links. Hunt, in his "Law of Boundaries," says:—"The idea which prevails very commonly in the country, that the owner of a boundary-fence, consisting of a bank with a ditch on the outside, is entitled to 4ft. of width for the base of the bank, and 4ft. for the ditch, is obviously an error. Such a doctrine would enable the owner of the ditch to cut into his neighbour's land till he obtained the requisite width for his ditch." In "*Vowles v. Miller*," the rule as to ditching was clearly laid down, the upshot of which shows that no rule about 4ft. or 8ft. has anything to do with it. No man can cut a ditch into his neighbour's soil, but he may cut it as wide as he likes on his ownland. The party who makes an inclosure digs his ditch on his own ground, and erects the bank in the inside. According to this theory, which is the only reasonable one, the boundary-line is coincident with the outer edge of the ditch, and hence, when two estates are separated by a hedged ditch, the legal presumption is, that both ditch and hedge belong to the owner of the land on which the hedge is

planted, though, of course, evidence may be brought to prove the contrary. Sometimes, there is only an old bank remaining between two properties, without a trace of a ditch, or there may be an old hedge with a ditch on each side, and the question of ownership may become a disputed point. In these cases ownership may be proved by acts of one party, as repairing the bank, clipping the hedge, or cleansing the ditch. If both owners can prove such acts, a tenancy in common is established. It would lessen much inconvenience and doubt if these general principles were kept in view, and if surveyors agreed among themselves upon the width to be allowed for ditches, quickset hedges, repairs, &c. Where there is no agreement between owners, the party who makes the fence must make it entirely on his own land. They regulate these matters better in the United States, for, by the statutes now in force, adjoining owners have to make and maintain a fair proportion of the fence between them, and each party is liable to contribute to its erection or reparation.

THE SPECIAL LOAN EXHIBITION — SPANISH AND PORTUGUESE ORNAMENTAL ART AT SOUTH KENSINGTON.

CHIEFLY owing to the exertions of Mr. J. C. Robinson, who was instrumental in enriching the South Kensington collection with many fine specimens of the various arts of Spain, and of Mr. Francis Cook (Visconde de Monserrat in Portugal), a fairly representative collection, as far as circumstances would allow, of works of Peninsular art has been got together in the right-hand hall at South Kensington, usually devoted to loans of china, glass and objects of *virtu*. In addition to the examples furnished by the South Kensington Museum itself, the description of which occupies no less than 96 out of 208 pages of the Catalogue, a fact showing how well the Peninsula was scoured for the benefit of the Museum, there are splendid contributions, many of the very highest interest and value, by her Majesty, the Kings of Portugal and Spain, the Duc D'Aumale, cathedral, conventual, and municipal bodies of Spain and Portugal, and a large proportion of the choicest collectors in Spain, France, and England. The Catalogue seems well prepared; but for reference it is a pity that in the larger collections numbers were not annexed to the articles, as was done ordinarily. It is true that each object has a cutting from the catalogue placed in front, but for some reason the numbers are cut off. Round the room are gorgeous specimens of textile fabrics and embroidery, many of the church vestments being of rare beauty and sumptuousness. The most remarkable specimen of this kind is No. 69, Mantle of the Infante Don Philip of Castille, brother of Alphonso X., richly woven in gold and silk. It is all the more curious for having a Cufic inscription, written from right to left and *vice versa*, running round the edge. This and the biretta, or cap, of the same Prince, embroidered in silk in various medallions with eagles and castles, were taken from the tomb of the Infante in Villacazar de Sirga. They are sent by the National Archaeological Museum at Madrid. The actual banner used at autos-da-fe is exhibited. Though not strictly within the conditions of the exhibition, some fine manuscripts are shown, dating from the 10th century to the 18th. Most interesting, and very remarkable for their comparative accuracy, are several beautifully-finished atlases—M. Spitzer's is the best.

There is nothing of greater consequence, or showing more dexterity of workmanship,

than the metal-work generally. Before the French invasion, probably no nation in Europe possessed such superabundance of church and other plate. From the Cathedral of Leon alone they took away 10,000lb. of old silver. It took ten camp-waggons to carry away the spoil from the Escorial in 1510. As it is, few countries could exhibit more important examples of their productions. The National Museum of Madrid has been lucky enough to secure a part of the Visigothic treasure found at Guarrazar near Toledo, the greater part of which is a conspicuous object in the Hôtel Cluny Museum at Paris. This specimen (No. 35) formed the arms of a processional cross, of gold and precious stones, of a distinct Byzantine type, showing, however, a great falling off from the earlier work. This, and many other works, show well how little really original art Spain has at any time produced, notwithstanding the great technical skill of the people. Ecclesiastical vessels abound. No. 130 is a very large chalice, as we often find in the earliest examples. It is very plain—in fact, a bowl on a low stand, the knob being ornamented with gold filagree and jewels. The date is fixed by an inscription saying that it was offered by Dulcia Regina (wife of Sancho the First), and so of the thirteenth century. It is not always easy to fix a certain date by the style in the Peninsula, for the workmen retained old types far longer than in England, France, or Italy—another proof of their want of inventive instinct. Nos. 103, 108, and 366 are all interesting chalices, of nearly identical shape and style, but the latter is supposed to be more than 100 years older than the others. They are of a similar shape to No. 130, but not so large. No. 367, from the collection of M. F. Spitzer, is a good instance of the common admixture of Gothic and Renaissance ornament. One of the grandest examples of the goldsmith's craft in the collection is a large monstrance, silver-gilt and jewelled, belonging to the Academy of Fine Arts, Lisbon. The open-work Gothic canopy is elaborate in the extreme. The middle portion seems to have been strengthened, a hundred years or more later, by two bold, but too heavy, Renaissance brackets. The date inscribed is 1104. The same owners show a first-rate specimen of late 17th-century work, a chalice, No. 112. The monstrance belonging to the Duc D'Aumale, which was formerly in the Cathedral of Braga, is unsurpassable for the richness and intricacy of its parts, shrine, and canopy work, enriched with small buttresses, pinnacles, and figures. His ewer and salver, of Portuguese work, are also very fine. There are innumerable jewels and enamelled ornaments, many of which, though found in Spanish or Portuguese churches and collections, were doubtless importations from other countries. A fine onyx of Philip the Second is a notable instance. Amongst the splendid domestic plate for which Spain has long been noted, nothing surpasses the ewers and plateaux of the 16th century, such as Nos. 362 and 363, the property of Mr. F. Spitzer, or No. 257, exhibited by Baron Seillière, and another by Sir R. Wallace. There are so many fine things of this kind that it is invidious to particularise. There is a profusion of finely-wrought spoons, jewellery, and personal ornaments. Of course the collection is strong in iron and steel work. From the Royal Armoury of Madrid, through the kindness of the King of Spain, we have a sight of a fine suit of half-armour, formerly worn by King Philip the Third, and two suits made in Pampeluna for the same Prince when young. His Majesty also exhibits a pair of stirrups made for the Emperor Charles the Fifth, by Alonso Micergillo, in the year 1535. They are simply marvellous for their chasing, engraving, and damascening. It would

require a volume properly to describe the riches of this kind—swords, maces, daggers, guns especially, and shields—which are to be seen in this exhibition. Very rare and very beautiful are the two Hispano-Moresco shields from the Royal Armoury. No. 20 is of the beginning of the 16th century, No. 21 is of the 15th. Each is of leather, elaborately embroidered in silk and silver, the latter with a religious inscription in Arabic characters.

Spanish and Portuguese ivories, except of early date, are not usually of a high class, and so in the present collection few of the ordinary type are exhibited. Of the more precious kinds we have several admirable specimens; foremost among them, and in fact equal in interest to most of the choicest ivory carvings in Europe, is No. 41—an ivory crucifix, presented to the Church of St. Isidoro of Leon, in the year 1063 A.D. The figure is placed, as in early Limoges enamels, upon a background—in this case, carved at the edges with a fringe of figures of grotesque dragons pursuing men. It, perhaps, may represent the state of torment in Hades, before the resurrection of Christ, which is represented in a small panel above the head of the Crucified. On the back the Evangelistic signs are represented at the four corners of the cross, the Holy Lamb, very stiff and conventional, standing in the middle. The intermediate space is filled by interlacing foliage, in the midst of which are fights of centaurs and other figures admirably designed and executed. It is difficult to imagine that an artist capable of inventing and carrying out such fine ornamental work could not have modelled the principal figure better. It seems most likely that he took the literal view of Isaiah's words "without form and comeliness," and so made the Saviour as ugly as he could. This view is supported by the extremely hideous bronze crucifixes belonging to Mr. Cook, &c. The nails originally were indicated by four inlaid spots—as the eyes are. The three large iron nails, one of which has broken the right hand, are comparatively modern. No. 42 is also a fine early piece—not altogether original—the back having been made up of various old fragments. It is of the 9th century. The figures representing the Beatitudes being arranged under semi-circular arches in pairs. There are several lovely circular boxes of the Hispano-Moresco period. One of the very best (No. 322) belongs to M. le Baron Davillier. Mr. M. F. Spitzer, among his other wonderful possessions, shows two very large ivory statues nearly 2ft. high, partly coloured, very stiff, and not without something of grotesqueness; but still the most important figures of the date (about 1320-30) that we have seen. The only other ivories worth mentioning are some coffers with metal mounts and ornaments in gold and colour upon the plain surface.

Of wood-carving and inlaying there are many interesting specimens. No. 315, a tabernacle in boxwood, of the latter part of the 15th or beginning of the 16th century, could not easily be equalled. In very minute figures the Jesse-tree is introduced as part of the decoration. This is a cabinet gem; but there are also many examples of a more substantial kind. The cabinets from Goa, in imitation of the finest Indian inlaying, are admirable. Mr. M. E. Odier's coffer of wood, covered with thin plates of copper, done by the Spanish Moors for the Christians, is well worthy of notice. No. 45, a pulpit of the 15th or early 16th century, is noticeable for its combination of Gothic and Renaissance detail. In pottery we do not learn much more than we already know from examples that have been long familiar to us. The finest early piece is No. 52, shown by the National Archaeological Museum at Madrid. It is a large wine-jar, jarron, or tinaja, in the style of Granada, very delightful in tone

and colour, light blue with light metallic lustres, though, alas! much injured by age. There are also fine pieces of lustre ware of different dates, all good in their way. Lady Charlotte Schreiber is the principal exhibitor of Spanish porcelain. She is to be congratulated as possessing two or three of the finest plaques, in imitation of Wedgwood, that have ever been produced out of England. In conclusion, we would draw attention to the painted-wood and terra-cotta figures, some of which were embellished by such good painters as Alonso Cano. The necessary painting of sculpture has always been a matter of great difficulty, seldom successfully met in our time, except, perhaps, in some of the lovely work of our dear, lost friend, William Burges.

CEMENT TESTING.*

By DR. W. MICHAELIS, of Berlin.

SINCE the criterion adopted in judging of the quality of Portland cement is the degree of cohesive strength which it attains mixed with 3 parts by weight of sand, and immersed in water for a definite period, and since in the testing of cement two other bodies enter into combination with it, the result naturally depends, apart from the nature of the cement, on the one hand on the quality of each of these bodies (viz. sand and water), and on the other on the method employed in the preparation of the briquettes for testing. It is evident that the finer the sand the greater will be the amount of surface exposed to the binding action of the cement; the latter will, therefore, be the more diffused, the result being loss of strength. The endeavour to obtain, even with the poorest quality of cement, the minimum strength stipulated in Germany—10 kilos. per square centimetre (142lb. per square inch) after 28 days—has led to the adoption of a sand as coarse in the grain as possible,—viz., such as is obtained by means of two sieves, containing 60 and 120 meshes per square centimetre (400 and 800 per square inch) respectively. Compared with the ordinary quality, this might more appropriately be named quartz gravel; it is obtained with difficulty, and is much more expensive, weight for weight, than the cement to be tested with it. In view of the fact that 3 parts of it must be used to 1 of cement, this may appear worthy of consideration.

Since the salts of carbonic and sulphuric acids, as known for a considerable period to professional men, exert, even in very small quantities, a material influence on the setting and hardening of quick-setting cements, and since the water employed in preparing the mortar for testing contains very variable quantities of these salts, it is inadmissible, especially in the case of thorough examinations, to leave the quality of the water entirely out of account. Not only, however, in scientific investigations, but also in the ordinary course of testing, this circumstance should be kept in view, since the same cement prepared with hard and soft water shows a variation which is by no means inconsiderable. Although the method of preparation of tests promises to become in the future a uniform one, it may nevertheless be of general interest to record, in a tabulated form, the variations which may be produced by different treatment in the preparation of the briquettes.

The following series of tests which were instituted at the time of the first official inquiry into the subject of cement testing in Germany, and which have now been brought to a definite conclusion, were occasioned by the above considerations.

I. In the first place, it was necessary to establish the difference in strength between

* Communicated by the Author.

a cement mortar of 1:3 and one of 1:5. (We may remark at the outset that only clean sand was used in all these experiments.)

(a) With the employment of a sand passing through a sieve of 60 meshes per square centimetre (400 per square inch), and retained upon one of 120 meshes per square centimetre (800 per square inch), but with the spheroidal grain of ordinary sand.

(b) With a similar sand, the grain of which lay between sieves of 60 and 240 meshes per square centimetre (400 and 1,600 per square inch), i.e., 50 per cent. between the 60 and the 120 and 50 per cent. between the 120 and the 240.

(c) With a sharp, angular-grained sand, such as does not exist in nature, and which is obtained by crushing quartz. The size of grain was that between the 60 and 120 mesh sieves.

The preparation of the briquettes was purposely carried out in precisely similar manner.

Every number furnishes the average of 20 single determinations.

Description of the sand.	Cement.	Sand.	Age.	Strength per sq. inch.		Water per 100 parts dry substance.	
				Hardened under water.			
				Tested wet.	Tested dry.		
(a) Sand between 400 and 800 meshes per sq. inch.	1	3	7 days	121	411	13	
			28	171			
			90	202

(b) Sand between 400 and 1,600 meshes per sq. inch.	1	5	7 days	64	290	13	
			28	100			
			90	122			
			270	136			
	1	3	7 days	122	200	13	
			28	168			
			90	170			
			270	109			
	(c) Sand (crushed) between 400 and 800 meshes.	1	5	7 days	70		12.5
				28	109		
90				109			
270				109			

The briquettes were prepared in the following manner: 500 grammes (17.6oz.) of cement, and 1,500 grammes (52.9oz.) of sand were thoroughly mixed in a dry state, passed through a sieve containing 400 meshes per square inch, and again mixed. 240 grammes (8.4oz.) of water were then added, and the mortar thus formed was well worked up until it was rendered thoroughly homogeneous. The moulds were at once filled with this mortar by means of a few light blows with a wooden mallet. The superfluous mortar was then removed, and the surface rendered smooth by means of an ordinary straight knife.

The quantity of water added was such that the mortar formed was in every case of similar consistency.

Those briquettes which were broken in a dry state, were removed from the water eight days before testing.

It follows from the results obtained from these examinations that:—

1. The difference in strength proceeding from the employment of a sand between 400 and 800 meshes, and one between 400 and 1,600 meshes, is so slight as to be scarcely worthy of notice. It is quite immaterial which of these sands is used; the latter (400 to 1,600) is preferable on account of the price being only half that of the other.

2. It is unnecessary that the sand be of a

sharp, angular character; it is sufficient that it be clean.

3. In the case of mixtures of cement and sand the tensile strength (as also the crushing strength) of dry briquettes is about 50 per cent. higher than that exhibited by moist briquettes. It may be remarked that in the case of neat cement the reverse occurs, in consequence of disintegration (decomposition of the hydrosilicate of lime) through desiccation. The sand employed in all of the above examinations consisted principally of quartz; a small portion may have been composed of felspar.

II. The following series of tests were carried out with a view to determining the influence exerted by the quality of the water on the strength.

Whilst observing a strictly similar treatment as regards other conditions, there were used in the preparation of these tests:—

(a) Distilled water.

(b) Spring water.

Every number is the mean of 20 single determinations.

The sand employed was of a mixed grain, viz., one of which 25 per cent. passed through a sieve with 4,000 meshes per sq. in., 45 to 50 per cent. through one with 1,300 meshes per sq. in., and 25 to 30 per cent. through one with 144 meshes per sq. in., i.e., such a class of sand as is constantly met with in nature.

The method employed was that described above, two proportions of water being used, because it had been invariably proved that with a sand of this quality the proportion of 12 of water to 100 of the dry material afforded more favourable results than that of 10 parts of water to 100 of the dry material.

Cement.	Sand.	Water.	Age.	Tensile strength in lbs. per square inch.
1	3	12 Spring Water	7 days	118
1	3	12 Distilled Water	28 ..	160
1	3	10 Spring Water	7 ..	110
1	3	10 Distilled Water	28 ..	155
1	3	10 Spring Water	7 ..	106
1	3	10 Distilled Water	28 ..	146
1	3	10 Distilled Water	7 ..	96
1	3	10 Distilled Water	28 ..	135

It will be remarked from this table that:—

1. Hard water gives on an average 6 per cent. higher results.

2. If the proportion of water be too small, the strength of the mortar is unfavourably influenced thereby.

III. In the following series of tests for establishing the influence of the method pursued in the preparation of the briquettes, the questions treated of under I. and II. were introduced to the extent of using three qualities of sand of different size of grain, and also different kinds of hard water.

The sands were:—

(a) That between 400 and 800 meshes.

(b) That between 400 and 1,600 meshes.

(c) The mixed grained employed in II.

The water used was:—

1. Spring water as in II.

2. A considerably harder quality of water coming from calcareous soil.

The methods employed were:—

a That described under I.

3 That which is now customary in Germany, viz., 500 grammes (17.6oz.) of cement and 1,500 grammes (52.9oz.) of standard sand are thoroughly mixed, 200 grammes (7.05lb.) of water are added, and the mass is worked up with a trowel until it presents an appearance of perfect homogeneity. With this mortar the moulds are at once filled and heaped up. It is then beaten in with an iron trowel of 150 to 200 grammes (5 to 7oz.) weight, at first lightly and afterwards more heavily until it becomes somewhat elastic; the superfluous mortar is then scraped off with a knife, and the surface levelled by means of the same, as under a. (See "Regulations for the

Uniform Delivery and Testing of Portland Cement.")

The briquettes were prepared by two persons, and each employed for the first time the method familiar to the other.

Each number under a and b is the mean of 5 tests, in the average column therefore of 10.

Cement.	Sand.	Kind of sand.	Water per 100 dry substance.	Age.	Tensile strain, lbs per sq. in.			Method of preparation.

1	3	"	10	7	158	154	156	a
1	3	"	10	28	171	212	191.5	
			harder water.					
1	3	a	10	7	202	216	209	a
1	3	"	10	28	230	235	232.5	
1	3	"	10	7	221	216	218.5	
1	3	"	10	28	208	203	205.5	b
1	3	"	12	7	146	150	148	
1	3	"	12	28	182	192	187	

The cement used for all of these examinations was "Stern" cement.

This comparative investigation proves that:—

1. The standard method gives the highest results, because in it the mortar is beaten more compactly into the moulds.

2. For coarse sand, such as a and b, 10 parts of water to 100 of the dry substance is the most favourable proportion.

3. With mixed-grained sand, 12 parts of water furnish more favourable figures; therefore, different sizes of grain require different proportions of water, which they likewise require in order to produce mortar of similar consistency.

4. The harder the water, the higher the resulting strength.

The explanation of this fact is very probably as follows:—By the separation of the alkali during the process of hardening, the carbonate of lime existing in the hard water is precipitated. This latter body is known, after lengthy separation, to become extremely compact and solid, and possesses in this condition high cementitious qualities, which, connecting themselves with those of the cement, must produce a higher effect. It is also well known that the sulphuric acid salts (e.g., gypsum), even in small quantities, exert a favourable action on the hardening process.

5. Ten kilogrammes per square centimetre (142lb. per square inch) after 28 days, by the method and with the quartz-sand prescribed by the German regulations, is a strength which any third-rate Portland cement may attain, and even Roman cement, which is known to give at least 50 per cent. lower results than Portland cement, may furnish such a result by this treatment.

6. By open structure of the mortar the increase in strength is small compared with that of the more compact mortar, showing that in the case of the loose mortar only the finest particles of cement adhering to the surface of the grains of sand come into action (on this account showing good results at seven days), but that through the coarser particles, situated at too great a distance,

the hardening process is impeded as compared with the more favourably, because more compactly, prepared mortar.

7. The mixed grained sand compared with the coarse sand (*a* and *b*) under otherwise similar conditions, gives 30 per cent. lower strength, and therefore the results obtained with the quartz-sand in general show far too high results, and run the risk of affording a false basis for the practical employment of cement.

DR. WALDSTEIN ON GREEK SCULPTURE.

LECTURE VII.

THE seventh and last of this course of lectures was a demonstration at the British Museum, illustrating the previous lecture at the King's College, Strand. Before proceeding Dr. Waldstein said he wished to direct the attention of the class to an interesting fragment of a marble shield, representing an Amazon battle. There could hardly be any doubt that it was a very sketchy reproduction of the shield of the Athené Parthenon by Pheidias. This so-called Strangford shield was of great interest, especially because of the two figures, one an aged bald-headed Greek, the other an armed warrior, probably the portraits of Pheidias and Pericles, which we hear were represented on the shield of Athené, and gave rise to one of the numerous accusations brought by the political opponents of Pericles against Pheidias. He begged the class to follow him into another room, where he described to them two statues of athletes binding the victors' hand round their brows (*diadoumenos*). The one was from Vaison, in France, the other formerly belonged to the Farnese collection. Authorities differed as to which of the two might be considered illustrative of the art Polykleitos, though they believed that the Vaison statue resembled most the extant Polykleitan Doryphoros, and represented the characteristics of that artist's canon, and he had described it in the previous lecture. It was, however, a considerably modified Roman copy.

He would now recall the description he had given of the Age of Pheidias, as that age manifested itself in the representative artists and in the conception and execution of their works, and of the corresponding transition to the succeeding periods. These changes in the character of the works of sculpture were most readily brought out in works of decoration, especially in sculpture in relief. In fact, he held that this class of plastic art was not pure sculpture, but stood on the boundary between sculpture and painting; and so the stricter laws of plastic art governing single figures in the round, did not apply with such firmness to this class of work. The transition from the spirit of the age of Hellenic Unity to that of the Peloponnesian Wars, from the simple broad and monumental style of Pheidias, to the more individual, mobile, and pictorial style of the succeeding periods, was well illustrated by the reliefs from the Temple of Apollo Epikourios, at Phigalia (Modern Bassæ), which we know was built by Iktinos towards the close of the 4th century B.C. The reliefs represented a Centaur battle and an Amazon battle. He directed their attention to the life and movement displayed in the attitude of the figures, as well as in the details, especially the flying drapery. It could not be denied that it was excellent work; yet, with all the comparative rest and dignity in the figures on the Parthenon, he maintained that had a fuller impression of life than was seen in these violently-moving figures. The longer we studied the Parthenon figures the more would it grow upon us, while the striking impression of the work before them would lose in strength with familiarity. The lecturer returned to the Elgin room, where he gave a full description of the east of the statue of Hermes with the infant Dionysos, recently excavated by the Germans at Olympia. The work by Praxiteles corresponded exactly to the description given of it by Pausanias, and it was found below ground on the very spot in the Temple of Hera where the ancient traveller saw it. In this work they would find the characteristics of the reflective, clerical and "romantic" mood which they had noticed in the illustrations of the works which have been identified as of Praxiteles. And this mood was carried out in the composition and in the execu-

tion of this admirable work. He had occasionally used the word "decline" for this period, but this did not mean to imply anything like subjective disapproval. On the contrary, he could not deny that works of this second Attic School immediately and strongly appealed to our feelings—perhaps because our age is more like the age of Praxiteles in many of its features. There was even no doubt an advance in the art of modelling, especially in the indication of texture, which they would notice in the blocky treatment of the hair, as contrasted with the smooth and elastic modelling of the nude, and in the rough fibrous surface of the drapery suspended to the tree. They would notice a similar style of modelling and of general conception in the beautiful statue of Demeter of Cnidus in another room, one of the finest works in the Museum, which had been added to the collection by Mr. C. J. Newton. Dr. Waldstein then proceeded to the room containing the sculptures from the Mausoleum of Halicarnassus, and after an historical sketch of this monument he proceeded to point out the characteristics of the art of Skopas, as shown in these remains. Finally, he dwelt upon the art of the Roman period, and in illustration of the difference between this art and the pure Greek work, he compared the Hermes (formerly of the Farnese collection) in the Græco-Roman room, with the Hermes of Praxiteles which they had just examined. This Græco-Roman Hermes was an adaptation of the type laid down by Praxiteles; but a certain affectation in the attitude, as well as a somewhat mercantile technique, as compared to the purely artistic modelling of the Hermes, must be ascribed to the style of Roman workmanship, where art becomes an *article de luxe*, and not an immediate expression of the deep inner wants and aspirations of an essentially artistic people such as the Greeks. He would finally beg them to examine some of the Roman busts, which were of high excellence. The feeling for individual personal life was highly developed in the Romans, and here they did good work. It is a common phenomenon that in periods when ideal art was at a low ebb the portrait still maintained its full vigour. He might merely mention the works of Bernini and his school, and refer to much sculpture and painting in our time.

Dr. Waldstein writes to correct a misstatement in our report of his lecture of the 21st June, saying:—"I alluded to a difference of opinion, with regard to the classification of the sculptor Polykleitos, between Mr. Murray and myself, especially because I had recommended the students to read his book. But it was as far from my words as it was from my intention to attribute 'a perversion of historical facts' to that archaeologist."

EXCAVATIONS AT CARNAC.*

THIS volume is the result of explorations in the neighbourhood of Carnac in Brittany. The author, the late Mr. James Miln, whose death occurred while the book was being printed, published some "Archæological Researches" in that locality in 1877, and the present work is a continuation of the same undertaking, and describes the author's researches among the alignments of menhirs at Kermario. The mounds at the Bossenno called Caesar's Camp were excavated, and the results of the work were embodied in the first book. The excavations amongst the alignments of Kermario were first prompted by a discovery of a Roman brick, and the author proceeds to describe in order the exploration of each field, these being illustrated by a general plan of the alignments and the remarkable Roman and Celtic remains found among them. The "the field of menhirs" as it is called, is the first part described, and the maps and plan of the early constructions engraved give a fair idea of the rude primitive stones exposed to view. The author illustrates by lithographic plates the objects found during the excavations on the floors of one of these erections, which consist of coarse pottery, Gallo-Roman and Celtic ware. The most important "find" is the upper part of a bowl in black Gallo-Roman lustrous ware, besides fragments of a spindle-whorl in red paste, ornamented pottery of rude character, horses' teeth, implements in

quartz, arrow-heads, &c. The illustrations which follow, of fragments of pottery of Celtic character, the menhirs and the remains found among them, are interesting, and impart to the reader a pretty correct idea of the discoveries, many of which are remarkable.

In the seventh alignment a fireplace was discovered, rudely constructed of stones, laid dry in a sort of moat. Flint-chips, charcoal, ashes, fragments of Celtic pottery and implements were found in clearing out the moat. We cannot devote space to follow the author into the detailed particulars of these discoveries; but we gather that between Kermario and Kerloquet there is a line of defensive works erected by the Celt anterior to the Roman invasion; these were occupied partly by the Romans on their arrival, who constructed more substantial works in certain positions. Among the Celtic works the long talus is placed, and the author points out that the "Romans must have been cognisant of the alignments of Carnac, and had no scruples in utilising them." It would be tedious and unprofitable to give at any length the conclusions of Mr. Miln without a map, reference to which is constantly made. Speaking of the alignments consisting of ten rows of undressed stones called menhirs, the author describes them as composed of a close-grained granite of greyish colour, which changes into red when subjected to a strong fire, indicating the presence of iron. The menhirs have the cubic and quadrangular forms of cleavage natural to granitic rocks, and the stones partake of the character of those of the district. Alluding to the age of the alignments, the author instances the proof of their being older than the walls, as some of the menhirs belonging to the alignments are built into the walls which are obviously of early Roman origin. Further evidence in favour of this opinion is adduced from the peculiar weather-markings and grooves to be seen in one of the menhirs of the 10th alignment, an overthrown monolith, which markings are estimated to be produced by an exposure to the atmosphere for centuries, and show conclusively the position it had formerly occupied and stood in to have become so grooved by the action of the atmosphere. The author concludes the alignments must have been erected as sepulchral monuments. Ashes, charcoal, flint-chips, pottery, &c., have been found at the base of the menhirs as in the case of dolmens. Into the elaborate question of the correlation existing between the alignments, cromlechs, and dolmens we cannot enter; suffice to say the conclusion arrived at by Mr. Miln is that these rude constructions are the mutilated remains of an immense necropolis, the construction of which must have extended over a long period. The work is well illustrated, and cannot fail to enlist the attention of antiquaries.

LAND-SURVEYING IN PENNSYLVANIA.

IMPROVEMENTS in the present methods of land-surveying carried on in the United States have recently been made the subject of a convention of engineers and surveyors in Pennsylvania. A Committee of the "Engineers' Club," of Philadelphia, was appointed to promote the subject, and questions were issued in circulars, to which numerous replies were received, suggesting the most important points for discussion. The principal of these replies had reference to the magnetic variation and its causes; the location of a true meridian line in each county; fixing corners and marking lines; location of lines independent of the needle; location of street lines; triangulation; examination and fees of surveyors; periodical tests of instruments; erection of permanent monuments; metric system; creation of a state board of engineers, &c. The communications are chiefly confined to these questions, and we find a few suggestions of value, such as the establishment of a system of triangles in each township. The author of this proposal, Mr. George Platt, county surveyor, Erie, suggests that a base line of 500 ft. or more be carefully measured on level ground in each township, and that at its ends permanent trigonometrical points be set up securely. At a point which will form an equilateral triangle or nearly with this base line, another point will be established, and the angles at base very accurately measured so as to reduce any error. In this manner the other two sides can be ascertained, and the triangle may be used to afford bases for

* Excavations at Carnac, Brittany. By JAMES MILN. Edinburgh: David Douglas.

other triangles. The angle of the base line with the true meridian ought to be found, which would govern the bearings of the different triangles in each township. The periodical testings of chains and compasses, and the examination of surveyors, were generally regarded as necessary. Opinions were unanimous upon the unreliability of the needle for correct work, on account of yearly and diurnal variations, local attraction, &c., and various plans of establishing a true meridian are hinted. Mr. Kaufman alludes to the broad belts of iron ore which manifest strong local attractions and render the needle very unreliable in places, and to the badly-centred and sluggish needles used by surveyors. In chain work it appears matters are worse; and it is conducted in a very slovenly manner. The chainmen are furnished usually by the landowners, and are often labourers: the work is done by turns by neighbours who happen to be present to see the lines run along their own land, and as soon as their tracts are passed, they disappear, and others take their place. Little effort is made to keep the chain straight or taut, or to carry it level over hills and valleys, and the accounts of the "pins" are seldom tested. A survey of the State in blocks of one mile square, the intersections being marked with proper monuments, was proposed as one of the alternative schemes. It may be mentioned a statute requiring surveyors to compare their compasses with an established meridian line, and adjust their chains by a standard measure, was passed in 1850, but does not seem to have been generally complied with.

The proposed Act to provide for the better regulation of surveys in Pennsylvania is too formidable a document to transcribe. There are 15 sections; a board of State surveyors is proposed to examine candidates for the practice of land-surveying in this commonwealth, and issue licences to those deemed competent; the board is also to establish meridian lines, examine and approve instruments, &c., and establish rules and regulations to insure accurate work. All lines are to be run to the true meridian, and the magnetic bearing noted: the use of the magnetic needle to be avoided as far as possible, and the angles of intersection of all lines given from the vernier, and all measurements in surveys shall be made with improved steel measuring chains, lines or rods, or such other accurate methods, as may be allowed by the board, to be tested by the standard United States measure, and shall be reduced to horizontal measurement; in marking angles in surveys of property, or of roads, landmarks of stone are to be used not less than 24 in. long with one end squared 5 in. by 5 in. Lines of township to be marked also by stones, not less than 3 ft. long with end squared 8 in. by 8 in., set in ground so as to project 6 in. above the surface, &c. The other sections allude to the duties of county surveyors, their qualifications, &c., and these regulations are to begin from the 1st of January, 1882. Such are in general the recommendations which were made at the convention, and an Act somewhat more condensed has been prepared and submitted to the Legislature by the executive committee of the convention and has been under consideration. The proposed regulations will place land-surveying on a better footing, and will make it unlawful for any person to practise the profession until he shall have passed an examination before the State Board; those only being excepted from the operation of this provision, who shall have been engaged in his profession as surveyor for 15 or more years at the time of the passing of the Act, and who may receive a license without a technical examination. The Government Survey of the United Kingdom has rendered a similar Act almost unnecessary among surveyors in England, Scotland, and Ireland; yet the day is not far distant when English land-surveyors, among others, will deem it to their advantage to possess a diploma, or to require some kind of test of proficiency from their members.

THE CITY GUILDHALL.

AT the annual meeting of the London and Middlesex Archeological Society, on the 22nd of June, Mr. Horace Jones, the City architect, read a paper upon the Guildhall, in whose council-chamber the members were then assembled. Built a few years after Westminster Hall, the Guildhall bore, he said, in some of its features a resemblance to its contemporary; it was much smaller, although in proportion more

lofty and better adapted for hearing in than the Hall. The Guildhall was second only to that edifice in the civic buildings of England. It was built for three purposes—(1) chiefly for the assembly of the guilds and meetings of citizens for election of mayors, sheriffs, and burgesses in parliament, or for discussions; (2) as a court of justice for trials of the highest kind at the Hustings Court, as well as trivial offences and the recovery of small debts; and (3) as a banqueting hall. The first Guildhall of which he had been able to find mention was referred to in 1212. The second Guildhall and its chapel, according to the Corporation rolls, was in building from 1326 to 1379, and a portion of the crypt of this building still existed, under part of the present hall, but was much defaced by fire. The only entrance to that Guildhall was from Aldermanbury. The present, the third Guildhall, was begun to be built in 1411 by Thomas Knowles, then mayor, but as finished was very different from the building in which they were met together. They had probably entered by the south porch, which consists of two divisions formed by an arch and columns, crossing in the centre and vaulted. The wall on either side is divided into small compartments, with tracery and quatrefoils. The groined roof with the stone ribs springing from the sides are intersected in the centre with sculptured bosses, having various devices and the arms and bearings of Edward the Confessor. Above the porch is a commodious chamber, approached by an external staircase, still possessing the remnants of panel tracery and canopied niches. A well proportioned and wide archway leads from the porch into the hall itself. This apartment, 152 ft. long, and averaging 49 ft. 6 in. wide, is divided into eight bays by seven buttresses on the north side and five on the south. At the corners are four massive turrets, with circular or spiral staircases in each, communicating between the hall, its crypt, and its roof. Between each buttress is a lofty window filled with stained glass, representing various scenes of civic history, including the Restoration of the City Charter, 1688; the Reception of the Five Kings by Sir Henry Picard; the Dream of Rahere, minstrel to king Henry VII. and founder of Bartholomew's Hospital; the Death of Wat Tyler, &c. The clustered shafts, dividing each bay, internally project 2 ft. on each side, and their height to springing of arch-ribs is 3 ft. The height from the present pavement to the underside of ridge is 8 ft.; the collar of beam between the queen-posts is 29 ft. long, and was cut out of timber 2 ft. 8 in. square. The east window, which is nearly the width of hall, is filled with stained-glass executed by Messrs. Clayton and Bell, and presented as a grateful offering by the Lancashire Operatives in memory of aid offered during the cotton famine; the west window has a memorial to the Prince Consort. The *coup d'œil* of the hall, with its stained-glass, its monuments to Nelson, Wellington, the Earl of Chatham, and his illustrious son William Pitt, and Beekford, the quaint wooden effigies so dear to *Punch* at the west end, and the massive open roof of oak, presents a grand and dignified appearance, and which need not fear comparison with any similar structure. This roof, it is well known, is a modern one, and there is reason to suppose, from descriptions of the effects of the Great Fire of 1666, which injured this building, that the original roof was not dissimilar to the present one; others suppose that it either had or was intended to have, stone ribs and vaulting, as at Mayfield Hall, Sussex, and other well known if not numerous buildings of the same period. The crypt is one of the most ancient and perhaps the finest example of the kind now existing in London. It, however, only extends under the eastern portion of the hall. It is divided into three aisles of equal width by two rows of piers, which are clusters of four small pillars with plain capitals, from which the arches and groins spread over the roof. The bosses at the intersection of the arches are, many of them, very large and bear shields of the arms of Edward the Confessor, of the City, and some well carved roses. In close contiguity to the Guildhall, on the north side, stands the Court of Exchequer, built soon after the Hall, in the 3rd year of Henry VI. The Court of Common Council held its meetings till 1614, when a new room, now the Aldermen's room, was erected at a cost of £1,740. A flat ceiling now covers the Exchequer Court, which was formerly united, and the chief windows are stopped up; all that

remains, indeed, of its decorative features are two niches of figures at one end and a curiously ornamented square-headed doorway near the entrance.

ARTIFICIAL VENTILATION.

THERE are many who believe ventilation should be effected by an artificial process, in which mechanical appliances, such as rotating fans, ought to be employed in impelling air into buildings. In a recent paper read before the American Society of Engineers, the author endeavours to show that no system is so independent of accidental natural conditions as that of impelling air by direct means with a fan wherever it may be required. The fan adopted in the United States Capitol is referred to as being the type of most of those used in America. This consists of fan-blades or vanes placed upon the face of a disc, and the fan thus made is placed in front of a circular opening in the wall of building, "the wall forming one side of the zone of blades, in opposition to the outer edge or face of the disc. In this construction no case whatever is required for the fan, which receives its air through the central circular opening in the wall, and delivers its air at all points of the periphery into a large but close room, from which room ducts for conveying air branch in any desired direction." This kind of fan was taken from a type described by a French author, M. Combes, in *Aéragé des Mines*, though slightly altered. The most efficient number of blades is found to be about 16, and the fans are generally driven by an engine directly connected, or by a belt and pulley from an independent engine. In arranging for ventilating machinery of this kind, the author gives the following rule: For a hall occupied by occasional sessions of one and a half hour, 10 ft. may be taken as the total quantity of air needed per minute, while for an assembly hall for long sessions, 30 ft. may be taken as a maximum. The sectional area of duct near the fan is got by dividing this figure by 600 (the desirable rate of flow of a forced current in a duct per minute). This rule, stated without algebraic symbols, gives the diameter of a fan which receives its air on one side only, as 0.073 times the square root of the number of feet of air to be moved each minute. The inlet or air-duct to a fan should, for the supply of air, be 1.4 times the area of outlet, and the areas of distributing ducts should be increased to compensate for resistance of air in small passages: the area of each branch in fact will gradually increase or become trumpet-shaped, expanding from the fan inwards. It is necessary also that these air-ducts be smoothly formed, have all the angles rounded, and be unobstructed; the outlets should also be extended so that the velocity of discharge be not greater than 2 feet per second near the surface. The direction of the discharge or efflux should be upwards. The ducts for removal ought to be also of sufficient size and of equal dimensions, and it is justly pointed out that the labour of impelling air is lessened by the ascensional currents of air in the building due to the difference of temperature, so that greater power is needed to impel the necessary amount of air in warm weather. In the design of the main education-shaft some care has to be taken to avoid down-currents and to prevent eddies. The points of junction of the ducts with this main shaft must be properly formed, so as to assist in the ascending current and not leave spaces for return currents. Into the details of boilers and heating surfaces we need not enter here, though the loss or transmission of heat by windows and exposed walls in every case must be taken into the calculation. The volume of air to be admitted per minute ought to depend not entirely on the size of the room, but on the amount of heating surface necessary to warm it, and a certain area of exposed outer wall or window surface. Mr. Briggs, in the paper we have referred to, enters into various steam-heating arrangements, such as coils, and much of what he says may be accepted as a contribution to the subject. Architects, and those who plan buildings, have much to answer for in not providing suitable ducts and chambers for heating apparatus and distributing flues in order to render efficient the plans of the engineer. Mr. Briggs' remarks are accompanied by illus-

trations of the fan used by him, with a table giving the diameter, revolution per minute, quantity of air delivered, horse-power required to deliver air at certain pressure, and sectional area of delivery duct. The idea of a ventilating tower receiving its air from a relatively pure level is revived, and a sketch is shown of one with a fan and auxiliary-coil chamber with underground ducts. As to height, the purest air, it is asserted, is to be found from 6 to 40 ft., and the most impure, 70 ft. to 90 ft. above level of ground—a statement rather at variance with the opinion of many who have proposed to ventilate large buildings by drawing air from considerable elevations. We believe, however, that over any great city, such as London, the stratum of air above the chimney-level is the most impure, and air brought down from such a level must be largely impregnated with smoke and gaseous exhalations. Every one knows what a dense cloud or haze settles over a large city on a still day, and any tower, to be of service, ought to pierce this stratum of the atmosphere.

SOCIETY FOR THE PROTECTION OF ANCIENT BUILDINGS.

THE fourth annual meeting of this Society was held on Friday at Westminster Palace Hotel. The American Minister, the Hon. J. Russell Lowell, occupied the chair, and in opening the proceedings alluded to the deep interest which his fellow country people felt in the ancient buildings of Europe and especially of England, and added, that while he sympathised in the main with the objects of the Society in so far as they uttered their protests against obliteration executed in the name of restoration, he could not allow that an old building should be allowed to tumble down rather than that it should be repaired, as he understood the opponents of the Society alleged was the opinion of some extreme men.

Mr. William Morris, M.A., hon. sec., read the annual report, in which the Committee, while expressing their belief that the principles of the Society were being more and more accepted, but confessed that "ignorance and thoughtlessness are so busy, and so entirely unchecked by any more direct influence than that opinion of cultivated men of which they knew little or for which they care little, that the destruction of the art and history of our ancient monuments is still going on with terrible swiftness, both in this country and elsewhere; and unless those who really care about the preservation of these treasures bestir themselves, and sacrifice some time and money to furthering a distinct agitation against restoration, it will not be long before there will be no ancient building which can be looked on by men of sense and knowledge without suspicion and discomfort; and very few which will be able to sustain a claim to be considered as ancient buildings at all." The report proceeded to enumerate the cases in which protests, generally unavailing, had been uttered against works of alteration of old buildings, these including the Magdalene Bridge, Oxford, proposed to be widened; Wimborne Minster, about to be repaired at a cost of £3,000; Oakwell Manor House, of which the committee made a careful survey for the owner; Stratford-on-Avon, where the opposition to the intended rebuilding of the tower and spire had caused Mr. Butterfield to decline to act as architect; Ashburham House, Westminster Cloisters, to save which a special committee had been formed, and the Town Hall of Genignano and the Bigallo, Florence. The operations of the Society were hampered by the smallness of its funds. The Hon. Percy Wyndham, M.P., moved the adoption of the report, and in doing so defended the Society from the charge often brought against it, that it preferred to have a building reduced to ruins rather than see it restored. The chief of the demolition of the City churches appeared at first sight to be one of the strongest that could be put for destruction, but a recent report to Parliament had proved that the funds realised by the sale of the sites of churches, for the erection thereon of business premises, had not resulted in that increase of churches elsewhere or the augmentations of poor livings that was anticipated. Mr. R. Stewart Poole, of the British Museum, in seconding the resolution, referred to the progressive destruction of ancient Arab monuments in the neighbourhood of Cairo, and Miss Amelia B. Edwards entered minutely

into this topic, and stated that the injury to the monuments of Egypt was partly due to the carelessness of the Government and theupidity of the natives, but chiefly to the English speaking tourist, who bribed the people to sell relics and fragments, scratched his ignoble name on every available surface, and incited the guides to blacken and injure the tombs with torches, bonfires, and magnesium lights. Miss Edwards suggested that the Society should correspond with Professor Masperou, the successor to M. Mariette Bey, as to the best means of checking these acts of destruction. Professor Sheldon Amos having also spoken on the wanton defacement of Egyptian monuments, the report was adopted. Mr. George Howard, M.P., moved the first resolution, and appealed for wider and greater pecuniary support to the Society, which he should like to see constituted a Court of Appeal in all matters of restoration. Mr. C. Kegan Paul, in seconding the resolution, remarked that the Society occupied the position of an *avvocato del diavolo* to structural restoration, inasmuch as it adopted an attitude of opposition to any projected repair or rebuilding till it should be shown by the proposers that the work was necessary and would not injure the building. The injury done to Wimborne Minster in the restoration of 20 years since, and to numberless other edifices before and since, showed the utility of such a society as this. Mr. W. Morris having spoken at considerable length on the manner in which the town and colleges of Oxford were being transformed and robbed of interest by the restorer and the utilitarian, the resolution was carried, and a vote of thanks to the Chairman, moved by Lord Houghton, closed the proceedings.

ST. PAUL'S ECCLESIOLOGICAL SOCIETY.

THE members of this Society visited on Saturday afternoon three parochial churches on the Metropolitan boundary of Essex. That of *East Ham* was the first church seen, and within it a paper written by Mr. G. H. Birch was read, in the author's absence, by Mr. A. Paxon, hon. sec. of the Society. The church is a small one, chiefly of the Transitional Norman period; it consisted of aisleless nave, western tower opening to nave by a Late Norman arch, chancel also Norman, and apsidal sacristium. Several of the windows are widely splayed lancets, cut through the thick walls, but one or two are modern Decorated windows or plain casements. On internal north wall of chancel is a richly-treated Norman arched, having intersecting arches decorated with the chevron, and traces of similar work exist on the south side. The walls of chancel and apse retain traces of mural decoration of the 14th and 15th centuries. The church is a typical specimen of an unrestored building. The chancel and nave are filled with high, square pews, covered by dingy green baize. The Norman arched below the pew ledge is painted and grained, in imitation of some wood known only to the grainer; in the chancel, close to pulpit, is a very large enclosure, comfortably cushioned and provided with a modern stove of uncompromisingly ugly pattern; in the apse is a large Jacobean monument to Edmund Nevill, 7th titular Earl of Westmoreland, inclosed by a large railing, which prevents the altar from occupying its proper place; the tower arch is blocked by organ-gallery, the chancel arch is replaced by a beam, stating that "this church was repaired and beautified, A.D. 1816," beside which are hung the Creeds and Commandments; the walls appear to need structural repairs as well as thorough cleansing. Mr. Birch, in his paper, severely commented on these matters, remarking that the present condition of the church ought to delight the Society for the Protection of Ancient Buildings, but reminded him of the text, "How dreadful is this place." The vicar, the Rev. S. R. Reynolds, acknowledged that the church was in a bad state, but the parishioners had refused to sanction plans for restoration prepared by Mr. Butterfield at the instance of the lay rector, who was a clerk in holy orders, the Rev. R. F. Wilson. The members next paid a hurried visit to the large church of *Bark up*, which has the peculiarity of having two north aisles to nave, as well as a south aisle, the arcades being of Late Perpendicular character. The nave and chancel have elaborate plastered ceilings of Jacobean character. Here Mr. Hugh Romieu Gough, F.R.I.B.A., read a

paper in which he traced the history of the great Benedictine Abbey which formerly stood to the north of the church; of this building, whose abbess was one of the four who were Baronesses by right of station and claimed precedence over all others, the only remains were the foundations of the eastern end of Lady-chapel, excavated a few years since by Mr. J. King, of Barking. Attention was called to the 15th century Gatchouse tower at the entrance to the churchyard, the upper story of which was formerly a chapel of the Holy Ghost. *Rainham Church* was the last place visited. It is a very small unrestored building, almost entirely in the Transitional Norman and Early English styles. It comprises low thirteenth-century west-tower, with shingled dwarf spire, a nave separated from shallow aisles by massive square piers, having scalloped capitals and moulded angle shafts, and a chancel, furnished with pews (in one of which is a richly carved stall elbow) and low forms. The east-end was walled up, apparently in 1768, but the reveals of a circular window and several lancet lights show on the exterior the former beauty of this thirteenth-century east front. A stove-pipe pierces the white-washed vault over chancel; the floors have been altered to a uniform level, and the whole church is covered with one roof, blocking up peculiar ranges of oviform clerestories in the nave. Mr. Gough read a paper in the church, which he said was the only one dedicated to SS. Giles and Helen; its founder, Richard de Lucy, Lord of Dixe, and Governor of Falaise, died in 1179. He called attention to the noteworthy features of the church, including the hagiocope and remains of rood-screen near chancel arch, the areaded work in nave, and a so-called leper's window in chancel. Mr. H. W. King, secretary to Essex Archaeological Society, said he had never heard a more satisfactory explanation of these low side-windows than that propounded by Mr. J. J. Cole, who quoted John de Peckham, a writer of the early portion of the fourteenth century, as authority for supposing that they were used for ringing a handbell to announce to the parishioners the elevation of the host. In churches on the Continent, built round by houses, similar side-windows existed high up in the chancel walls.

CITY CHURCH AND CHURCHYARD PROTECTION SOCIETY.

THE second annual meeting of this Society was held on Thursday, the 23rd inst., at the Egyptian Hall, Mansion House. The report stated that since the founding of the Society no City churches had been destroyed, but it was to be feared that a more drastic scheme might be prepared on the publication of the Census returns. At the beginning of the Parliamentary session notices were served on the rector and vestry clerk of St. Mary at Hill, again threatening the church with destruction and the churchyard with desecration; but attention being called to the matter, a saving clause was inserted in the Bill. A detailed report had been made as to the condition of each of the City churchyards by the hon. secretary, Mr. H. Wright, and those which were not found in a satisfactory condition formed the subject of correspondence between the Society and the responsible authorities. The report concluded by remarking that the City churches have peculiar and special claims upon the world and the Church, and the success that had been so rapidly attained by this Society, was chiefly owing to the widespread interest in these edifices, most of them the work of one remarkable man at an eventful epoch in the growth of modern England. The report was adopted on the motion of Messrs. H. C. Richards and C. Kegan Paul, and a second resolution moved by the Rev. Canon Venables (Lincoln), and seconded by the Rev. Canon Shuttleworth (St. Paul's) expressing satisfaction at the success of the Society's efforts, was unanimously adopted, as was also a resolution pledging the meeting to support the council in carrying out the Society's objects.

ACCURATE JOINTING IN IRONWORK.

THE value of accurately fitting the joints of buildings has been pointed out by all authorities on construction. In stonework and terra-cotta laying, too much attention cannot be given to the bed-joints, so that no inequalities

of surface exist; and all builders know the importance of bedding the stones of columns and piers evenly to prevent fracture or "flashing at the joints." All surfaces should be fitted with accuracy. "Where iron comes in contact with stone or concrete," says Mr. Matheson, "the inequalities of surface may be made good with lead, iron cement, Portland cement, or bitumenised felt; wood, if joined to iron, will adapt itself to the harder material; but iron and iron will not in certain positions fit properly unless the surfaces are faced in the lathe or planing-machine." As an example he instances a tier of iron columns supporting floors. Although these may have been carefully designed the strength is often reduced one-half by bad fitting. A heavy load causes undue strain to take place, and the tier of columns is weakened, or the pressure, instead of being transmitted in the line of axis, comes on one side, causing dangerous strains of a bending nature. In other instances, the floors sink, or excessive strain comes upon certain parts. Machine processes are now so cheaply performed that, as Mr. Matheson says, the saving in first cost by the neglect of much precaution is only trifling.

THE SCIENCE AND ART OF SANITARY PLUMBING.—IV.

TRAPS AND TRAP VENTILATION.

THE Society of Arts room was again crowded on Tuesday evening by an interested audience, on the occasion of Mr. S. Stevens Hellyer's fourth lecture on plumbing. The special subject was the siphonage and ventilation of traps, and was illustrated by numerous practical experiments, as well as by diagrams. Mr. Noble Smith occupied the chair.

The lecturer remarked that there were many traps which befuddled themselves besides the \odot and bell traps already examined and condemned in his third lecture; but before passing on to consider self-cleansing traps, he must refer to some of the former class used outside the house in connection with drains. The first of these stoneware traps he would notice was the Mansergh-trap, which although it had only been in use a few years, had an extensive sale, and was much liked by many. He condemned it, first, because it was non-cleansing; and, secondly, because it did not leave the end of waste-pipes (discharging into it) open to the air. The illustrations on the wall would show all practical men that this flat-bottomed, trunk-shaped trap did not cleanse itself. The body of it was shaped like a box with a partition across it dividing into two unequal compartments for holding water in each. An opening was made in the middle or upper part of this partition for the discharge to pass from the inlet compartment to the outlet compartment. A dwarfed partition was taken down from the top of the trap to screen the outlet and to prevent the drain-air from escaping. A round, bent pipe, called the "inlet," was found in the side of the inner compartments for receiving the end of a waste-pipe, and this pipe was dipped into the "standing water" of the trap. The outlet of trap, a round pipe, was at the opposite angle. Provision was made for ventilating the drain with which the trap was connected. A large opening over centre of top of trap was made for receiving surface-drainage, and also for allowing any gases generated in the trap to escape through the grating, instead of passing through the inlet to the sink or lavatory-waste into house. A trap of such construction was by necessity dirt-holding; it must become a "collecting box," for there were no less than eight corners for filth to accumulate in, and no amount of water sent through such a trap could be made to scour the parts fouled. The bottom was flat, the sides were vertical, the partition dividing the two compartments was upright, and the area of the surface water of trap was several times greater than its inlet or outlet; so that the standing water of the trap, with its decomposing matter, could not get changed by any single nor by many flushes of water sent through its inlet. The bad air from this contaminated body of water, if it did not escape through a waste-pipe into house, would at times get in through a window or door. Again, the arrangement of inlet was bad in principle; for it water-locked the discharging end of waste-pipe, instead of allowing it to be exposed to the atmosphere. Another evil in

connection with this trap was that the waste-pipe discharging into such a trap, being trapped at its remotest end from sink, exposed the house to any bad air or decomposing matter left in such a waste-pipe. This trap was not, therefore, of a right kind to receive water from sinks, lavatories, or urinals, as such water, remaining in the trap, would become offensive. The lecturer here exhibited drawings of a trap which he designed some years since for receiving waste-pipes, and intercepting them from the drain. This trap had three dips to prevent drain-air from reaching the ends of waste-pipes discharging into the waste-receiving compartment, and like the Mansergh trap it had two separate bodies of water. It was specially constructed for receiving waste-pipes from baths and lavatories when fixed on bedroom floors and for protecting them from the drains. It had, he claimed, two important advantages over the Mansergh traps: 1st, it left the end of any waste-pipe discharging into it open to the atmosphere; 2nd, the bottom of the trap was rounded, and its configuration made it easier to cleanse. But this trap was not self-cleansing, or as much so as he wished it to be—i.e., an ordinary flush or flushes of water sent through it would not cleanse it. When a trap could not be thoroughly cleansed, and the whole of the water standing in it changed by a good flush of water sent through its waste-pipe it ought never to be used; and so, though he held a patent for it, Mr. Hellyer said he condemned it. He had also illustrated the well-known gully-trap, because it was now being used for receiving waste-pipes from sinks, &c. It might be a good trap for catching detritus, and therefore just the one for use in yards and streets for surface-drainage; but as traps for receiving the discharge from waste-pipes were not wanted for "catching" anything, it should not be employed for sink, urinal, and lavatory wastes. It formed a catch-pit for filth, and ordinary flushes would not cleanse it. He would now consider the much-used drain-siphon for trapping off sewers. This being a round-pipe trap, would be self-cleansing, if it had no manhole and was provided with means for a waterfall into it. But no pressure of water was (or only very rarely) brought to bear upon the standing water of the trap, and consequently it never became perfectly changed by a flush of water sent into the drain. Then the manhole formed a collecting place for filth, and soon needed cleansing. Another defect in this siphon-trap was its want of ventilation. When foul matter was discharged into a trap, with a water-flush after it, it should pass through it, leaving no substance behind. He hoped to prove that certain traps which he had called "self-cleansing" did this; but before doing so, he would lay down the principles on which they should be constructed, and the conditions on which they should be fixed. (1) The trap should be free from all angles, corners, and places where filth could accumulate. (2) A free way should be made for the discharges to pass through the trap without breaking their form; i.e., the trap should be like a round pipe, so made or bent as to form a water seal. (3) The body of the trap for fitting in horizontal pipes or drains should be smaller than its inlet, so as to hold as small a quantity of water as possible, consistent with the position in which it would be placed and the work it would have to do—to admit of easy changing every time a flush of water was sent through it. (4) The minimum-sized trap should be used consistent with circumstances, but governed somewhat by the size of the waste-pipe or drain on which it was fixed, and the flush of water likely to be sent into it. (5) The water-way into a trap for fixing the flat-bottomed vessels with gratings over its mouth should be larger than its body part, or than the waste-pipe with which its outlet might be connected, so as to be able to send efficient water flushes through the trap to cleanse it, and also to cleanse its waste-pipe. When the trap was smaller than the waste-pipe, no good flushes could be sent through such piping to cleanse it. (6) The inlet or mouth of the trap should always be so arranged that the flushes should fall upon the standing water of the trap with a vertical pressure, so as to drive everything foreign out of the trap and to entirely change its previous contents. (7) The inlet side of all traps fixed upon drains outside the house should be open to the atmosphere in some way, so that any bad air

rising from foul matter decomposing in the trap or coming through it from the drain or sewer might readily pass into the open air, or be largely diluted with fresh air before passing into any waste-pipe, soil-pipe, or drain discharging into such traps. In cold countries, where the water standing in the trap would be liable to freeze in severe frosts, the mouth of trap should be sealed over, and the foot ventilation or air-induct should be taken into the waste or soil-pipe, or drain, some little distance away from the standing water of the trap, to prevent the cold air currents from playing upon it and freezing it. In this country in sheltered places there was little risk, and if the trap (for dis-connecting) was kept well down into the ground in exposed places, there was no danger from frosts.

Ocular demonstrations that round pipes were self-cleansing were now given on the platform, and occupied a long time; Mr. Hellyer being frequently interrupted by suggestions for making the experiments more complete and fair, or questions as to the modes of working. The lecturer explained that in order to show the working of the insides he had had the traps made in glass. Having coloured the water in his round-pipe trap by putting blue water into it, he passed a small flush of clean water into the trap from the basin, when the whole of the blue-water was washed out and the trap left clean—a result greeted with loud applause. Next, indiarubber cut into small pieces was put into the trap, and was completely flushed out by the discharge from the handbasin; plumber's soil and gravel were next put into the trap, and equally well removed by a flush of water. A glass \odot trap was then used, and after several flushings remained half-full of plumber's soil. But these round-pipe traps, the lecturer added, had a defect in that they were siphoning traps, especially where long vertical legs were attached to the outlets. Unless such siphonage could be prevented, such traps were not only useless but dangerous. By another series of experiments it was shown how in practice traps were often siphoned and thus unsealed. A model bath and lavatory basin were fitted up on a stand, and by discharging a small quantity of water from the bath the lavatory on the floor beneath was unsiphoned. By discharging a basinful of water in this lavatory the trap to bath above was similarly unsiphoned. Experiments with the \odot -trap and Bower-trap showed that though these were not unsiphoned with anything like the ease that the other traps had been, they were by no means proof against the action of discharges through the pipes on which they were fixed. Like siphon traps, they required ventilation. In these \odot and Bower-traps the water was much agitated while flushes were passing through the piping, and water was to some extent siphoned out of them by any discharges, although not, perhaps, enough to unseat them. Next, the stop-cock was opened so as to ventilate the main waste-pipe at top and bottom, and, by letting a little water through the bath-trap, it was unsiphoned, notwithstanding that the main waste was well ventilated. He thought he need hardly say to practical plumbers that unless siphonage could be perfectly remedied, round-pipe or self-cleansing pipes were worse than useless, for while they would impede the cleansing force of the discharges through the waste pipes, they would be no protection to the house. If absolute safety was needed, the Eclipse, the Bower, and even the \odot -trap must be ventilated.

He wished now to show, by one or two severe tests, that trap-siphonage was prevented by trap-ventilation. They would see that an air-pipe was taken out of the lowest trap and continued above the highest, branching into the main waste or air-pipe. Into this ascending air-pipe, from the lower trap, the branch air-pipe from the upper trap was taken, so that each trap was ventilated. He now opened the stop-cocks (which were shut during the former experiments) and gave the traps ventilation, when the waste was left undisturbed, or if disturbed, it was only very slightly in either trap, notwithstanding that full and rapid flushes were sent through the waste-piping. This was exemplified both with the bath and basin flush, and it was then shown that if the ventilating-pipe on the top of the main waste-pipe was shut off by turning the stop-cock, the result was just the same; so long as the ventilating pipe to the trap remained open, neither the working nor the idle trap were unsealed by good discharges sent

through the waste-pipe. A good deal of ignorance prevailed on this question of ventilation. Many simply ventilated the main waste or soil-pipe, but not the individual traps. They insisted on the soil-pipe being carried up full size to the open air, and, in some cases, were willing to give it foot ventilation, but were then satisfied. The lecturer had been amused, a short time since, by reading remarks on the "bends" of a ventilating-pipe to soil-pipe, written by a gentleman who was called on to report on some plumbing. He found two or three bends in a fin. ventilating pipe, and he wrote that the pipe should have been carried up "straight." If the gentleman had had more experience, he would have known that bends in pipes of full bore would make but trifling difference, and not enough to notice in a report. Mr. Pridgeon Teale, of Leeds, had rendered good service by his book "Dangers to Health"; but though he showed valuable improvements on old plumbing practice, his methods were not perfect. Some of his diagrams exhibited traps which would be readily unsiphoned. In a series of experiments the lecturer made a month since with a tier of lavatories discharging into a common waste-pipe, he found that if they were only ventilated by an open top to the waste, a painful of water discharged through any one basin partially unsealed them, and another flush unsealed all of them. The traps were then ventilated by taking a 1½ in. pipe from the outgo of lowest trap, continuing it up and connecting it with the air-pipe of the main waste above the highest trap, and branching 1½ in. air-pipes from the other traps into it on its way up. Three heavy flushes caused visible agitation in the other traps; but they only lost 1-16 in. of water, and the trap flushed was left fully charged. The experiments had been repeated, Mr. Hellyer said, with large pipes and traps, the results being precisely the same. Another arrangement of bath and lavatory wastes was shown in diagrams, and described as very commonly adopted. A bath was fixed on the chamber floor with 1½ in. waste-pipe from it to discharge in the open air. The waste-pipe from lavatory on ground floor was branched into the bath-waste, and though he had on diagram shown an air-pipe to top of waste, many people were satisfied with an opening to air at the discharging end. With both the air end and discharge end of waste open, the lavatory trap was not only siphoned out by the emptying of a bath of waste, but 130 ft. lineal of air was drawn through it into the waste-piping, as registered by an anemometer. Another test was made similar to the last, but with a Bower-trap instead of the 1½ in. "patent east-lead trap;" when the bath was emptied, the ball in lavatory-trap lost its seat, and 110 ft. lineal of air was shown by the anemometer as having passed through the Bower trap, which still, however, returned about ½ in. of water as a seal. An air-pipe on the Bower-trap prevented any action upon it by discharges through the waste-pipe. Another arrangement experimented upon was a stack of 2 in. waste-pipes with a bath and two glass slop-sinks upon it. There were no fewer than four traps placed upon the middle floor (or upper slop-sink) trap; a 2 in. "patent east-lead trap" was fixed under the bath and each of the two sinks, with 2 in. lead branches into the main waste-pipe. A 2 in. ascending pipe was taken off the top of the outgo of the lowest trap, and continued up and branched into the main air-pipe above the highest trap with branches from each trap connected with it on its way up. This ventilating-pipe was shut off when not needed by a stop-cock. The first experiment was made without trap-ventilation. The bath-cock was opened and the bath discharged; but before one-fourth of the contents had passed through the waste-pipe, all the traps to slop-sinks were unsiphoned, and ½ in. of water was drawn out of the first of those on the upper sink. The experiment was repeated, opening the ventilating-pipes, and though 60 gallons of water passed through the waste in 2½ minutes not one of the traps was unsealed.

A detailed explanation was given of the course of siphonage—i.e., the displacement of water in traps by discharges sent through a pipe on which such traps were fixed. Trap-siphonage was chiefly caused by the atmospheric pressure being greater on one side of the trap than on the other. When a body of water was sent through a soil or waste-pipe it interfered

with the pressure of air on the standing water in the outlet of the trap fixed on such pipes. The pressure of air being removed from the outlets the water was forced down on inlet side of the traps, and rising on the outlet side, it escapes through the branch-wastes, unsealing the traps, and allowing all to pass through them. To prevent the standing water from being displaced, the weight of air should be equipoised on both sides of seal, and this was readily done by fixing a ventilating-pipe on the outlet of the trap.

He had now, he thought, brought the trap question to its present point by easy stages (1) by showing that traps under sanitary fittings were necessary; (2) that the traps largely used for such purposes were unsanitary—i.e., non-cleansing; (3) that traps could be made sanitary—i.e., self-cleansing; (4) that self-cleansing traps, when fixed in certain positions, were easily unsiphoned, and so did more mischief than good; (5) they had found out how to remedy the evil of siphonage. All that remained to be done was to look at a few characteristic traps which were self-cleansing. The siphon or round-pipe trap, whether made of earthenware or lead, was self-cleansing, and although he wished plumbers to cease making O-traps, he did not want to prevent them from making traps. If his hearers could not bend lead pipes into siphon traps by hand, they could knock them up from sheet lead in two halves and solder them together. Mr. Hellyer also showed his V-dip east-lead trap, which he said was self-cleansing, and not so easily siphoned as the round pipe traps. Of outside traps were shown Buchan's stoneware trap for disconnecting pipes from drains and drains from sewers. This trap was self-cleansing. The cleansing-power was aided by its water-drop, and by having a vertical opening to the atmosphere right over the inlet, any sewer air passing through the standing water of trap could readily get away or be largely diluted with fresh air. In the lecturer's ventilating drain-siphon and sewer interceptor the principle was the same as in Buchan's. It had a greater water-drop, and the body of trap was much smaller than the inlet and the outlet. "Weaver's drain-ventilating trap," next shown, was a great improvement on the manhole drain-siphon; but the want of a vertical fall on the standing water prevented it from being so self-cleansing as it should be. The "Croydon siphon trap" had been largely used of late. It was infinitely superior to the old siphon, but was not absolutely self-cleansing, as the body of the trap was too large for the standing water to be washed out by a flush. In conclusion, the lecturer said many of these and other traps would be on view at the forthcoming Sanitary Exhibition at South Kensington.

PRACTICAL NOTES ON PLUMBING.—III.*

By P. J. DAVIES, H.M., A.S.P., &c.

JOINT-MAKING (continued).—SHAVING.

SHARPENING the shave-hook has been before referred to. Some plumbers throw this tool about as at Q, Fig. 1, or into their bag with hammers, chisels, files, &c. I wish to impress upon the young plumber's mind the necessity of keeping it free from notches by proper protection and care. Shaving may be learnt in a few days. You should practice on a piece of pipe to see how round and true you can shave it; shave it clean and even, not too deep, round the edge, see E.F., Fig. 6. Having all your work prepared, fix the joint together, as at section Fig. 5, which is a round joint to be made either upright or underhanded. You see at K that the male fits, but a little recess is left for the solder to get into. Many plumbers close this; they cannot do a worse thing, as it is very useful in joint-making. At Figs. 7 and 8, you see a full-sized 1 in. joint; this is how the joints should appear when finished; Fig. 7 is a short, and Fig. 8 a long joint. On examining the full-sized section, Fig. 5, you will notice the dotted lines H I, shows the outer line of the solder on the long joint, and F N, the outer line of the small joint. The small joint does not take the amount of solder of the large joint, and on further examining same across the centre of joint at D, you will perceive an equal thickness of solder, therefore the joints are equally strong

across the actual joint. There is one advantage with the long joint—it is easier to make, because you have a larger quantity of solder to play with, which retains the heat, and also a larger cloth; its length also renders it less liable to show imperfections as to roundness, &c. The large joint should be first practised upon, and then try to reduce same, keeping in mind that the centre thickness of solder is the principal point to watch. This substance of solder is generally about twice the substance of the lead at that point, not merely for strength, but for other purposes to be explained. Every plumber should know that solder is much stronger than lead, taking it bulk for bulk; still this thickness cannot be made the rule, inasmuch as some waters are chalybeate or impregnated with iron, &c., which readily attack the metals composing the solder; in such cases you must use discretion as to the substance of metal around your joint.

COLLARS.

Suppose you have your joint upright, as at Fig. 9, you will require something to catch your metal (solder); then, if you have a piece of sheet-lead handy, cut a collar, which is generally made by cutting it round or otherwise with a hole in the centre the size of the pipe; if too large, pack some newspaper between the collar and pipe. Well soil same and tie a piece of string round your pipe, as at A, Fig. 9, which will support the collar and prevent the solder running through; to support the outside part of the collar, tie your compasses as shown at M N, and the ends of the compasses will act as props, but if no compasses to hand two pieces of stick tied across the pipe, or an iron chisel or screw-driver driven into the wall, &c., will answer. The collar should be put on as shown at F G, as level as possible, as it is much better for parting your solder round the bottom. When fixed as at D E, the solder drops down and sets round the bottom, and is at times very difficult to remove without the iron, as it cools much quicker when in a small body.

Before you begin to wipe your joint stop the ends of your pipes to prevent draughts. "The metal's hot—bung it!" is the cry. During this time you should select your cloth. In this case, for a 1 in. upright joint, the size is 2½ in. by 2½ in. The metal's here: you give your cloth to the mate, who will get the face side warm by holding it over the metal-pot (or, if you can trust him, he will get your cloth for you and bring it ready warm). Take a felt, that is a piece of old carpet, 9 in. long or so to hold your ladle with, then take your ladle full of solder and set to splashing your metal on the joint with the splash-stick as shown at H, I, J, K, L, Fig. 9, taking care not to burn the pipe with the solder, that is, by splashing too much in one place; look sharp and get up your heat by getting on as much solder as you want, and as near the shape as possible. Keep it alive by working it up with the splash-stick. If it drops down push it up again with the stick, warm it up with fresh metal, keep at it until you have the joint to look as at I, J, K, L; now take another ladle of hot metal and splash it up the soiling about and round B. To get a little more heat on your lead, keep splashing and patting it up to the proper shape with your splash-stick. It is just hot enough; now take your cloth, well hot on the face side, in the left hand, and with a sharp sweep wipe quickly and clean round the top and back part of the left-hand side of your joint, then the bottom, next the centre, change hands and do the other side, that is, round I K, and finish by wiping down from B to H, and from H to K L, and your joint is done. Whilst hot, part your metal so that it will leave the pipe. You do not require an iron for this; keep practising at this until you can do it without. Pray don't use irons if you can do it without: you will do better hereafter. The time required to make this joint is about one and a-half minutes, that is getting up your heat and wiping included. The wiping alone should not exceed 20 seconds.

OVERCASTING.

Before we leave this kind of joint-making, let me say that in London you will not require to overcast your joints, as was the custom in the time of the old architect Vitruvius, 100 years before Christ, but when in the country you may, that is to say, when your solder has to be used very coarse. This is done as follows:—Suppose your solder to be four of lead and one

of tin, the solder would set quickly and be very porous; then you will want an iron to warm or liven up your solder. The same iron will do your overcasting, as follows: Having shaped your joint, well touch the same; take the handle part of the ball of the iron and rub it from bottom to top of the joint, just to glaze the joint, then bring it down again the same way; this gives the glaze or ribbed line, which should not exceed half an inch wide, G, Fig. 10. Next do H,

University College, and we find active preparations are being made in allotting spaces to exhibitors. The exhibition will be on a very extensive scale, the Committee having at their disposal the east and west quadrants, or annexes, of the Albert Hall, inclosing the Horticultural Society's Garden, besides the long eastern arcade leading to the eastern quadrant and the western gallery. Entering from the centre of Exhibition-road,

part. We find spaces have been allotted to some large firms. Messrs. Rosser and Russell, A. Smith and Stevens, Strode and Co., Crossley Bros., Bellman and Ivey, C. Drake and Co., Eureka Concrete Co., T. J. Constantine, A. Walker, Hobbs, Hart, and Co., T. Potter and Sons, R. W. Winfield and Co., F. Edwards and Son, Verity Bros., J. Weeks and Co., Musgrave and Co., occupy conspicuous stalls. The Universal Ventilating, Sanitary, and Engineering Co., Comyns, Ching, and Co., C. Kite and Co., J. Haworth, Ritchie, and Co., the Silber Light Co., have also stalls. Filtering apparatus, lighting and ventilating contrivances will be found in this quadrant. The corresponding western quadrant has been set out for medical exhibits of all kinds, and the exhibitors in this department are very numerous, though in both sections we find a few spaces still to let for single articles. In the sanitary section we must not forget to mention a long space in the east arcade set apart for exhibits of journeymen plumbers, which will attract some attention. A part of the western arcade is to be devoted also to a variety of medical and sanitary exhibits, such as extract of meat, disinfecting fluids, prepared milk, the Aylesbury Dairy Co., the Sanitas Co., and we understand it is in contemplation to show an electric railway in operation at the end of this arcade. Another of the plans shows the western gallery, which is devoted chiefly to medical objects. Those who require space should lose no time in applying for it. The exhibition opens on July 16th, and will remain open till August 13th. The plans are drawn to a large scale, and show the allotments, the names of exhibitors and the spaces unoccupied, and are signed by the chairman, John Eric Erichsen, F.R.S., president of the Royal College of Surgeons; and the secretary, Mr. Mark H. Judge, curator of the Parkes Museum of Hygiene. The superintendents are Messrs. J. Douglas Dick and E. Smithson, from whom all information as to space may be obtained.

CHIPS.

Mr. W. Mattien Williams, F.R.A.S., F.C.S., author of "The Fuel of the Sun," "Through Norway with a Knapsack," &c., has been appointed to the management of the Royal Polytechnic Institution, and commences his duties forthwith.

The *Rock* states that a considerable portion of the superstructure of the shrine of St. Frideswide at Oxford has been lately found thrown carelessly into a well in the rear of one of the Canons' houses at Christ Church. It is hoped that a further search will bring the rest of this most interesting structure to light.

Mr. F. J. Price, for some years leading assistant in the construction department of Mr. J. T. Chappell, 149, Lupus-street, Pimlico, S.W., has been elected to the office of Inspector of Works to the Plymouth Corporation.

At the Midsummer Quarter Sessions for Glamorganshire, held on Monday, the committee of lunatic-asylum visitors were instructed to procure a plan for the erection, in sections, of an asylum on the recently acquired Parc Gwyllt estate, to accommodate 700 patients. It was also agreed to enlarge the chapel at the present asylum from plans prepared by Mr. Alexander Bassett, C.E., county surveyor, from 240 to 300 sittings. The estimated cost was £500.

On Wednesday the Prince and Princess of Wales attended the opening of a sick asylum which the Guardians of St. Marylebone have erected in Backham-street, Notting-hill. The new building will accommodate 700 persons. The architect is Mr. H. Saxon Snell.

Mount Zion Chapel, Illogworth, is to be reopened on Sunday next, after repewing in pitch-pole, the substitution of a restrum for pulpit, and the execution of decorations, reglazing, and painting. Messrs. Leeming and Leeming, of Halifax, are the architects. Mr. J. Farnell is the contractor for joinery, and Mr. Carr, of Halifax, for decorations.

The local board of Old Swindon recently elected a Mr. Dickenson as surveyor, but at a recent meeting of the board it was reported that he had been attacked by mental illness. As Mr. Dickenson had discharged his duties satisfactorily, the generous offer of a member of the board, Mr. W. E. Morris, was accepted that he should undertake the duties, the salary to be paid to the wife and family of Mr. Dickenson. That officer has not recovered, and his resignation has been formally tendered and accepted, Mr. Morris continuing to perform the duties of surveyor while negotiations are going on with the local board of New Swindon for an amalgamation of the authorities.

taking care to let the outer line cut the glaze of G; next do IJ: begin at the other side and bring round as at L, M, N, O, and finish at K, or if you want it to look even all round, begin at one place and go all round until you come to where you began, keeping an eye to your ribbed lines.

INTERNAL "JOINT-WIPING."

In some cases when upright or underhanded joints it will be found impracticable to wipe round the back of the pipe; for instance, suppose you want to wipe a 4in. joint round a pipe which was lying within half an inch of a ceiling or wall, it would be impossible for you to get your hand round. In this case, prepare your joint as at Figs. 11 and 12, so that you may wipe half from the inside as at S, Fig. 12, which is done by cutting the pipe in front and opening same, of course you must wipe your solder flush with the pipe, III shows the soiling, and E, F, G, D, the lead laid open, PP the centre of the joint or lead; having wiped the inside, either close the opening with the lead E, F, G, D, or, as is much the best, let a fresh piece in and wipe it there, as shown at NKP, Fig. 13. When practical, use a short mandrel. When fixing the door put NKP, Fig. 13, be sure to have the water-way free from rough edges.

INTERNATIONAL MEDICAL AND SANITARY EXHIBITION.

AN exhibition of medical and sanitary appliances is to be opened shortly at South Kensington, under the auspices of the Exhibition Committee of the Parkes Museum of Hygiene,

the visitor finds a rather tortuous passage brings him to the eastern arcade, a very long corridor, about 600ft. in length and about 20ft. in width, skirting on one side the Horticultural Society's Gardens. Along the wall of this corridor numerous sanitary exhibits will be ranged, and we find, from the large plans issued by the Committee, the names of several well-known firms. Paint companies, such as the "Sanitary," the "Albissima," the "Silicate," have spaces near the entrance end; and we observe that Fred. Walton and Co., the Stone Drainage Company, G. Barnard, Shanks and Co., Thames Bank Iron Company, Willeck and Co., of Leeds, Joseph Cliff and Sons, J. E. Ellison, Banner Brothers, W. P. Buchan, R. Boyle and Son, G. Jennings, Tylor and Sons, Stiff and Sons, H. Doulton, Macfarlane and Co., W. Tonks, J. Warner and Sons, Haywood, Tyler and Co., Ilhee and Ilhorn have stalls among many other firms. From the end of this arcade extends the eastern quadrant, and here we find the large hall at the junction has been allotted to various exhibitors, among them to Howard and Sons, the Wilson Engineering Company, W. Ramsay, C. W. Durham, Crossley Brothers, F. W. Clark. The quadrant, or curved annex, forms an admirable building for the display of appliances of a sanitary kind, and being about 300ft. in length by 22ft. wide, there will be ample space for two lines of exhibits, one occupying the black-wall side and the other the window arcade, with a wide corridor between for the public. We find the allotment in this part is for sanitary objects, though every sort of manufacture or improved appliances and furnishing will be exhibited. Stoves and gas apparatus, ventilating arrangements, lavatories, and art metal-work will be very largely represented in this

PROPOSED QUADRANGLE, MAGDALEN COLLEGE, OXFORD.—
SOUTH HILL, BROMLEY.—HOUSES IN HARRINGTON-GAR-
DENS.—ST. CHAD'S CHURCH, HOPWAS.—COFFEE TAVERN
AND HOSTELRY AT NEWARK ON TRENT.

OUR LITHOGRAPHIC ILLUSTRATIONS.

PROPOSED NEW QUADRANGLE, MAGDALEN COLLEGE,
OXFORD.

THE drawing published shows the street facade of a proposed new quadrangle for Magdalen College, Oxford. It was submitted by Mr. Basil Champneys in a competition to which Messrs. Street, Bodley and Garner, and Wilkinson were also invited. Messrs. Bodley and Garner, whose designs were illustrated in the BUILDING NEWS for Dec. 24, 1880, were selected to carry out the work.

SOUTH HILL, BROMLEY.

SOUTH HILL, BROMLEY, by Messrs. Ernest George and Peto, is a compact little house just erected for Mr. Gainsford Bruce. The ground-floor is of red brick, and the upper story of weather-tiling upon quartering, banded and felted. The dining-room has an angle with settles, and the walls are panelled to the ceiling. The hall is panelled to the height of the doors, and the drawing-room has a panelled dais and an enriched ceiling in low relief. The bedrooms are all on the one floor, except an attic and a box-room above. The stables, with dove-cot, adjoin the offices. The weather-tiled gables are well grouped, and the house has a home-like, pleasant aspect. The contract for the house (without the stable) was taken by Mr. B. Payne, of Bromley.

HOUSES IN HARRINGTON-GARDENS, KENSINGTON.

Our illustration shows two pairs of houses by Messrs. Ernest George and Peto, now being built. The larger pair have the advantage of a corner site, the roads and gardens allowing the four elevations to be seen, three walls to each house enjoying windows. The houses are square in plan, avoiding the passage-like strip that generally accommodates a town house. The reception-rooms are entered from a square panelled hall in the centre of the house, well lighted and with a fireplace. The drawing-room is on the ground-floor, occupying the length of the principal front. On the same floor is the library and dining-room, with scervy by the back stairs, and small dinner-lift. There is also a larger lift for coats, luggage, &c., to the top of the house. By the entrance lobby is a good cloak-room and lavatory. In this larger pair of houses the billiard-room is in the principal gable of the roof, with lofty-arched ceiling, and the main stairs go to this room, which is

quite separate from the attics or servants quarters, approached from the back stairs. Externally the houses are of red brick, with brick mouldings, pilasters, &c., and the roofs are of red tile, while the window openings have casements with lead lights. These houses are to cost £18,000 the pair. The pair of smaller houses, costing £11,000, are somewhat similar in arrangement, but here the billiard-rooms are in the basement floor. They have, however, their own flight of stairs, connecting them with the principal rooms. In one house, which is building for Mr. Arthur Peto, there is an ingle-nook to the dining-room. This room is panelled to the ceiling.

SAINT CHAD'S CHURCH, HOPWAS, STAFFORDSHIRE.

THE above church, which has been built mainly by the exertions of the Vicar of Tamworth, the Rev. W. MacGregor, is situated on a beautifully wooded and elevated site just off the high road from Tamworth to Lichfield, about three miles from the former town. As will be seen from the drawings, a somewhat novel treatment, at least in church-building, has been adopted in the construction of the nave walls, which, from the level of the window-sills, are of timber-framing filled in with brickwork, the panels outside being cemented and left rough. The whole of the timber used inside and outside of the church is of oak; both the outside framing and internal fittings being left without having had anything put on them. The walls outside underneath the framing, &c., are of red local bricks; Codsall red stone being used for all dressings. The internal walls of the church are lined with warm-coloured buff bricks. The roofs are covered with brown Staffordshire tiles, and the spirelet is shingled. The work was carried out in a satisfactory manner by Mr. John Dakin, of Lichfield, from plans, &c., prepared by Mr. Douglas, of Chester.

COFFEE-TAVERN AND HOSTELRY, NEWARK-ON-TRENT.

THE coffee-tavern and hostelry shown in our illustration is to be built and endowed by Viscountess Ossington, for the benefit of the town of Newark, and will be carried out from the designs of Messrs. Ernest George and Peto. The building is arcaded along the principal front in the manner of many old houses in Newark. The arcade will form a pleasant shelter in hot or wet weather, and tables can be placed here for those who like outdoor refreshment in the "café" manner. There is also a large garden on the river-side of the tavern, overlooking the Trent, and its bridge (formerly a part of the town ramparts). This garden has an entrance from the bar, and here refreshments will be served, while music will be provided in summer evenings, after the custom of the pleasant German "Bier Garten." Along one side of this garden is an alley for American bowls. The ground-floor is occupied by a large bar, adjoining which, on the same floor, are the kitchen and offices. A smaller bar, separate but served from the same counter, forms a room for boys, a feature found very necessary, both for the comfort of the men and boys. There is also a small manager's parlour adjoining the bar. A separate entrance and staircase leads to a large assembly-room on the first floor, a room that will be used for concerts, lectures, and various large meetings, as well as for the farmers' ordinary on market-days. On this first-floor are also a reading-room and a club-room, for the meetings of the various friendly societies. The second floor is formed in the spacious roof, where is provided a large billiard-room for two tables. "Cubicles," or dormitories, for twelve lodgers, as well as for the rooms for the manager and servants. A bath-room is provided for the use of the cubicles, and lavatories, &c., conveniently for billiard-room, assembly-room, and the yard. There is also a ladies' cloak-room. Externally the building is treated with an arcing of red brick, and above these arches the mullioned bay-windows project. There are wide-spreading eaves and moulded cornices above, against which these bay-windows stop. Above are long mullioned windows, over which the gables are tiled in with oak framing and panelling, giving a rich effect. The tenders will be opened in a few days for this work.

A new police-station is in course of erection at Siltley, near Birmingham, from the designs of Mr. Luit, County Surveyor of Warwickshire.

THE ILLINOIS PLUMBING LAW.

THE Chicago Times gives the text of the law regulating the inspection of tenement and lodging-houses, recently passed by both branches of the Legislature of Illinois. We quote it substantially entire: "Any architect or architects, builder or builders of, or other person or persons interested in, any projected tenement, lodging-house, or other places of habitation, in any incorporated city of 50,000 inhabitants, shall submit plans and specifications of any such buildings to the Health Commissioner, for his approval or rejection, as to the proposed plans for the ventilation of rooms, light and air-shafts, windows, ventilation of water-closets, drainage, and plumbing.

"Any plumber or other person or persons interested in the contract for the plumbing work of such buildings, shall receive a written certificate from the Health Commissioner before commencing work on the said building or buildings, and shall proceed according to the plans, specifications, and instructions approved by the Health Commissioner.

"Any plumber, or other person or persons interested in the plumbing work, after the completion of said plumbing work and before any of the said plumbing work is covered up, shall notify, in writing, the Health Commissioner that said building is ready for inspection; and it shall be unlawful for any plumber or other person to cover up or in any way conceal such plumbing work, until the Health Commissioner approves the same."

The violation of the Act on the part of architects is punishable by fines of 100 dols. to 200 dols.; and on the part of any plumber by fines of the same amount for the first offence, and of 10 dols. additional for each day that, after the first conviction, he refuses to comply with the provisions of the Act.

The Act concludes as follows, expressing the conviction of the legislation as to the importance of the law: "[Emergency.] Inasmuch as the health of the people is endangered, an emergency exists requiring this Act to take effect immediately, therefore, this Act shall take effect and be in force from and after its passage."

ACTION OF FROST ON GAS-PIPES.

THE winter of 1879-80 will long be remembered throughout Central Europe as one of comparatively great and long-continued cold. The *Journal für Gasbeleuchtung*, 1880, contains an article on the "Action of Frost on Gas and Water-Pipes," being the experience of the engineer at the Karlsruhe Gas-works. At these works there are six gas-holders, the three largest of which are provided with small boilers for heating the water. In the present instance, however, this was insufficient to keep the tanks free from ice, which began to form in the interior of the small holders, while the water on the outside was several degrees above freezing. This certainly is a very unusual occurrence, for the circulation of the heated water from the outside, together with the higher temperature of the gas, would seem to be sufficient to prevent the formation of ice. The difficulty at Karlsruhe was obviated by passing a pipe into the holder and blowing steam in, which after two days removed the ice. A plan commonly employed in other works, is to place in the tank outside of the holder a steam-pipe from 1½ in. to 2 in. in diameter. This is arranged parallel with and about 2 in. below the surface of the water. The steam produces a circulation of the water around the tank and keeps everything free from ice during the coldest weather. The holder cups are kept clear by passing into them a small steam-pipe provided with joints which allow a rising and falling with the holder.

The article referred to also states that 4-8 per cent. of the gas-meters fixed in private houses were stopped by the frost, but were made to work again by the addition of glycerine or alcohol.

The choking of service-pipes with naphthaline is one of the difficulties generally experienced in the distribution of illuminating gas. At Karlsruhe it was easily removed by means of the force-pump. This treatment is not always effective however, and in many cases it is necessary to use a little methyl alcohol or some other solvent to remove it entirely from the services.

OUR COMMONPLACE COLUMN.

ORNAMENT.

MANY definitions of ornament have appeared, more or less correct, into which it would be unnecessary to enter, although a really scientific definition of the term would be a gain. Many people, and artists among them, fall into the idea of thinking ornament to be any addition to an object which merely enriches or embellishes it. Thus, they would call the most unmeaning detail or enrichment applied to an iron girder "ornament" as much as if it was really appropriate. Real ornament ought to add to the meaning and intention of the work to which it is implied, and impart effect and beauty to it, and perhaps Pugin's definition may be taken as a fairly good one. In his "Glossary of Ecclesiastical Ornament" he says: "Ornament, in the true and proper meaning of the word, signifies the embellishment of that which is, in itself, useful in an appropriate manner. Yet, by a perversion of the term, it is frequently applied to mere enrichment which deserves no other name than that of unmeaning detail, dictated by no rule but that of individual fancy and caprice. Every ornament, to deserve the name, must possess an appropriate meaning, and be introduced with an intelligent purpose and on reasonable grounds." So far as it goes, this explanation of the term is perfectly correct, though not quite satisfactory as a philosophical definition. The words "appropriate meaning," for instance, may be differently taken and expressed, so with regard to "intelligent purpose," which might be extended to a great many meanings by different minds. We think Fergusson's division of ornament into *constructive* and *decorative* a very useful one in architecture, as it serves to show that all ornament may, more or less directly, spring out of construction. Thus, a capital, a bracket, a cornice, are contrivances which arise out of the actual construction; and they became ornamental in an eminent degree as they give expression to the construction; but when they appear to fall short of or to exceed this function, they become unnecessary, coarse, and showy. Mouldings, frets, foliage, and such-like features, belong to the second class, though even these may be said to be only further removed from the actual construction. Indeed, it may be generally held that the less apparent the connection such features have to the construction, the less are they real ornament. In fact, we should say that *true* ornament is to be regarded as an organic outgrowth of the work of art inseparably bound up with the construction and functions of utility, and conceivable only by the artist as the perfection of his detail. When we come to analyse ornament, or to consider of what elements it consists, we find a few prevailing characteristics in it which admit of generalisation. We find, for example, in a Greek fret, or guilloche, honeysuckle, or egg-and-tongue ornament, a repetition of given lines, curves, or points, together with a certain variation, forming a pleasant sequence to the eye. It is possible to discover a general law of harmony in such a series in which simple elements are so mixed as to become rhythmical; a certain form is caught up and repeated at intervals, and in general we discover an alternation of harmonies and contrasts. Wornum, in his "Analysis of Ornament," alludes to contrast, repetition, and series as the leading elements. The history of ornament forms a very important indication of the progress of civilisation, and a very full bibliographical list will be found in the "Arch. Dictionary." It is not necessary here to describe the characteristics of the various styles of ornament, which are well-known; we may, however, give the names of a few of the leading works on the subject. On antique and classic ornament the following may be consulted:—Beauvallet and Normand's "Fragments d'Ornement dans le style Antique"; Penrose's "Ornaments of the Parthenon"; Villiamy's "Examples of Ornamental Sculpture"; Jenkin's and Hosking's "Selection of Architectural and other Ornaments, Greek, Roman, and Italian"; Cottingham's "Collection of Architectural Ornaments from Stuart's 'Athens, &c.'"; Gaudon's "Collection of Antique and Modern Ornament"; Redman's "Ornaments from the Antique"; Whitwick's "Selection of Vases, Chairs, &c., from the Vatican." Of Early and Mediæval ornaments the student may consult Colling's "Gothic Ornaments" and "Art Foliage," published in the

BUILDING NEWS; Pugin's "Glossary of Ecclesiastical Ornament," "Gothic Ornaments"; Zach's "Ornements d'Architecture du Moyen Age d'Angleterre et de France"; Waring's "Arts Connected with Architecture from 13th to 15th century in Central Italy"; Cottingham's "Drawings of Gothic Ornament"; Fergusson's "Celtic Ornamental Art"; Shaw's "Handbook of Mediæval"; Owen Jones's "Alhambra" and "Grammar of Ornament"; Le Conte's "Ornements Gothiques Renaissance." Of Renaissance and Italian, Late English and French, see Salandris's "Architectural and Ornamental Specimens of Italian Ornaments"; Adams's "Polychromatic Ornaments of Italy"; Baldus's "Recueil d'Ornements d'après les Maîtres des XV. au XVIII. Siècles"; Shaw's "Details of Elizabethan Architecture"; Wornum's "Catalogue of Ornamental Casts, Renaissance at S. Kensington Museum"; Mr. Audsley's "Japanese Ornament." We may refer also to the illustrations of ornament given in the BUILDING NEWS from time to time: See Davis's "Illustrations of Early Classic, Greek, Assyrian, and Egyptian ornament," in Vol. for 1868, XV., p. 604, and XVI., p. 99, XVIII., p. 228; the same author's illustrations of "Greek and Etruscan," in Vol. XIX., p. 470; also Burges's "Conventional Ornament of 13th Century," Vol. IV.; Davis's "Indian Ornament," Vol. XVIII., p. 480; of Mexican Art, Vol. XXIV., p. 445; papers by Colling, Statham, and Hulme on Principles, and many recent papers and contributions in recent volumes. G. H. G.

OXIDATION.

THIS very destructive process ought to be thoroughly understood by those engaged in building—at least, as it affects building materials. The oxidation of iron is now found to be principally owing to the carbonic acid in the atmosphere, and not the oxygen or aqueous vapour in it. The caustic alkalis are found to prevent the oxidation of iron. A humid atmosphere charged with acids is most destructive to iron, especially wrought iron; but oxidation is often accelerated by contact with other substances containing acid, and by galvanic action assisted by humidity in the air, as in the case of iron in contact with lead. Wrought iron is much more rapidly affected than cast iron. Steel oxidises more quickly than wrought iron, according to M. Mallet, and the degree of durability depends probably on the proportion of carbon. But though cast iron does not rust rapidly in air or salt water, it becomes soft and porous, and converted into a sort of plumbago. Paints are of little use where iron is exposed to damp or rain; Dr. Angus Smith's application of gas-tar or asphalt has been found advantageous for iron exposed to the action of acids; but a zinc coating is better for iron immersed in seawater, although the coating must be entire and perfect. The action of seawater on metals is decided, especially when the iron is exposed to the alternate influence of air and sea, as in the case of iron piles exposed to the rise and fall of the tide. See Craze Calvert's papers in BUILDING NEWS, Vol. XII, 312. Lead paints set up a galvanic action between the paint and iron, and are, therefore, more injurious than oxide of iron paints and bituminous paints. There are certain well-known methods of coating iron with bronze or copper, as in Turner and Allen's process. Barff's treatment by superheated steam, has also been described in the BUILDING NEWS, but seems better adapted for small articles than large structures of iron, as the articles have to be subjected to heat in a chamber raised to a high temperature, say, of 500° Fahr., and then steam be admitted into it and the articles kept immersed for 5 to 7 hours. Iron heated and covered with a coating of asphalt or mineral bitumen has been known to last a number of years, and various coatings of indiarubber, naphtha, varnish, paraffin, &c., have been found of use. Zinc-covered or galvanised pipes have been found to corrode when used as water-pipes. In setting iron in stone Portland cement has been found better than lead; and sulphur has been used in preference to it. We refer the reader to Mr. G. R. Burnell's remarks on this subject, to "Notes on Building Construction," and to Mr. Matheson's "Works in Iron."

OVEN.

THE construction of ovens, although a matter of everyday building, is not very generally understood. For baking purposes ovens

are generally built of brick; the dimensions of an oven are usually about 4ft. by 3ft. inside, either round or square, and from 18in. to 24in. high. It ought to be lined with fire-brick. The flue is towards the front, and serves to carry away the smoke of the wood fuel that is burnt, or the steam from the bread. A specification for a brick oven for a dwelling-house is given in the BUILDING NEWS, Vol. VI., p. 765; see also the Intercommunication Columns of this journal, Vol. XXX., p. 410, and Vol. XXXI., p. 485. A dresser for making bread, a kneading-trough, and a flour-chest, should be placed at a convenient part of the bakery.

UNIVERSITY COLLEGE AWARDS.

THE following are the awards in the architectural section of this college:—

Construction, Second Series. Donaldson Silver Medal. A. W. Glasson of London. Prize. T. R. Clemence, of London. Second Class. G. Havill of London. Third Class. A. Gillespie of Blackheath, H. W. Teed of London, Charles Turner of London. First Series. Prize. H. C. Clarke of London. Certificate 2. F. A. Gerrish of London. Second Class. F. C. Nichols of London, G. C. Nichols of London. Third Class. John Briggs of London, E. Crisp of London, H. W. Parkinson of London. —Fine Arts, Second Series. Donaldson Silver Medal. A. B. Cottam of Watford. Prize. A. W. Glasson of London. Second Class. C. J. Tait of London, K. Tatsuno of Japan. —Modern Practice. Prize. A. Ashbridge of London. Second Class. C. H. Bedells of Crouch End, W. J. Lander of London, C. E. Pertwee of London. A. B. Pite of London. Third Class. J. D. Butler of London, W. Grellier of London, W. A. Pite of London.

The students in the first and second series were this year examined separately. Several of them passed creditably on both occasions, but, following the precedent of other years, the council of the College have only granted to such students a certificate or prize for the more important of the two examinations.

The award of the Donaldson medal was made by Professor Lewis. That of the other prizes was made by other architects familiar with examinations, at the request of Mr. T. Roger Smith.

CHARITABLE AND PAROCHIAL ESTABLISHMENTS.*

BUILDINGS erected for parochial purposes, such as workhouses and infirmaries, have generally been so hampered by restrictions and regulations of an official character, that few architects have cared to publish examples of this class of buildings. Mr. H. Saxon Snell, F.R.I.B.A., has just brought out a selection of executed and unexecuted designs of buildings, meant to solve the question of how best to arrange buildings for the accommodation of the poorer classes, and as this is the first work of the kind devoted exclusively to the subject, it will probably be found of service to architects engaged in the planning of buildings of this class. The designs illustrated are exclusively the author's. They must be taken not as embodying the most perfect principles of construction, but rather as some approach to the solution of the problem. The great difficulty with architects intrusted with public buildings of this kind, as pointed out by Mr. Snell, is the disinclination of committees to contemplate any but immediate wants, the consequence of which is that when old buildings have to be dealt with a piece-meal scheme has to be adopted, instead of one contemplating ultimate remodelling on an approved plan.

In turning over the designs we meet with a variety of plans, from infirm-wards, added to St. Marylebone workhouse when workhouse construction was little understood, to designs for infirmaries based on the more recent principles of the Local Government Board. Of course there is little new or original in the arrangements, as every workhouse infirmary or ward is more or less a copy of another. St. Luke's workhouse for chronic and infirm paupers is arranged with the wards placed in the axis of the main building lengthwise. There are two male infirm wards for 42 beds, and two female infirm wards for 36 beds on the ground-floor plan; these are separated by the administrative block in centre, and by the staircases, lavatories, &c., in each wing. The chief peculiarity in the wards is the projection

* Charitable and Parochial Establishments. By H. SAXON SNELL, F.R.I.B.A., &c. London: B. T. Batsford, High Holborn.

of bay windows on one side; there are four of these to each ward, the beds being arranged transversely in rows. The advantage of this plan is that the wards combine the cheerfulness of day-rooms. There is a connecting corridor between the wards on each floor, and the bath-rooms are carried up as ventilating towers. St. Olave's Union Infirmary, erected in 1879, is another illustration, though it is chiefly an enlargement, and presents little of interest; St. George's Union Infirmary, Fulham-road, opened in 1878, is more perfect in the plan, especially of the sick-wards, which are arranged as pavilions, with recreation grounds between. The narrow spaces between the pavilions, and the planning of the conveniences, are certainly defects in an otherwise good plan. A bird's-eye view, plans, and sections of the Holborn Union Infirmary follow, a work we have already described and illustrated in the BUILDING NEWS, after which the newly-erected building for St. Marylebone Infirmary, Notting-hill (opened by the Prince and Princess of Wales on Wednesday last), is given. The wards are arranged as long blocks or pavilions, each of which has a centre block connecting each pair of wards with a day-room, nurses' rooms, stairs, and lifts. We do not like the architectural treatment of this infirmary so well as the one in the Fulham-road; the pyramidal-shaped roofs, springing from the summits of the end latrine blocks, have a very awkward effect. No less than four plates of plans and sections are given of this work. The other illustrations include a design for an infirmary with circular wards on Professor Marshall's principle, with the corridors thereto radiating from the administrative centre building, and the author quotes largely from the Professor's pamphlet, in which the advantages of this system are pointed out, and endorses the opinions expressed. Alterations and additions, a convalescent home for children at Norbiton, plans for casual wards, and designs for Kensington district schools, for an industrial school, a dispensary and proposed lunatic-wards at Hendon Union, baths and wash-houses are among the other illustrations, which are all photolithographs to a good scale. Perhaps the most useful portion of Mr. Snell's work is that treating on the data of cost and the extracts from Local Government Board Memoranda and other official documents relating to construction, which architects often require in preparing their plans. Details are also given of the combined casement and lifting sash for sick-wards, as adopted in most of these buildings, and also of the author's "Thermohydric fireplace."

PREHISTORIC RUINS IN ARIZONA.

DR. R. T. BURR, M.D. (U.S.A.), while exploring White River Canon, situated in the Chiricahui Mountains, in South-eastern Arizona, about 55 miles south of Camp Bowie, and 25 or 30 miles north of the Mexican line, has discovered the remains of an ancient settlement. The ruins are located in the forks of two branches of White River, or where Henley's Branch joins the main stream from the south. The land is at present a military reservation. They are less than 100 yards from either branch of the stream, on a ridge 40 or 50 feet above the river-bed. The land is rather rocky, but in many places there is excellent alluvial soil along the streams. In the vicinity of the ruins are at least 1,000 acres susceptible of irrigation. The canon has now a growth of pine, oak, juniper, some walnut, and a few sycamores. The surrounding mountains are well covered with pine and oak. It is impossible to tell what changes have taken place since these ruins were occupied. They must have been considerable, as the water supply in the dry season is now limited, the river ceasing to run, and only holding water in a few places.

Rucker's Spring is a large basin of water that contains as much at one season as at another. The water is strongly impregnated with sulphur.

The remains occur in groups, some consisting of from two, four to five squares or circles, showing that at the time they were built defence was not a primary object. Isolated in the heart of the mountains, this community would be first exposed to the hostiles, and probably fall a prey to the Apache invasion from the north.

The other two isolated groups are small, the nearest having three or four squares and no

circles; the second, on the east of Rucker's Branch, having five or six squares from 10ft. to 20ft. by 20ft. or 30ft. The ruins described seem to be the most important ones. Dr. Burr took a sketch of the ground-plan of the ruins. He traced out the walls of the main building as well as he could, the only guide he had being the upright stones placed singly from 6in. to 12in. apart. No remains of a wall exist save these stones that are placed on end and partly buried in the ground. Walls or lines are, with one exception, due north and south, and east and west. Dr. Burr tested this by means of a compass, and, making allowance for variations of the needle, they are certainly wonderfully correct. The walls, if they were walls, must have been made of adobe, and the heavy rainfalls of the canon, about 30 inches this year, would have destroyed all traces, as this building was erected on the incline of the ridge, while the circles are on the level ground. The large circles, all about 30 feet in diameter, have the walls much better preserved than the squares. The mounds are from 12 inches to 2 feet higher than the surrounding land, and, in some cases, spread out some 4 to 10 feet. The walls seem to have been made of adobe and stones.

Near the centre of most of the mounds is quite a depression, caused by the washing down of the walls. There are no evidences of special construction in the centre. The materials could be obtained in abundance in the immediate vicinity. On the ground Dr. Burr found an abundance of pottery in small pieces, some of it glassy, one piece ornamented in colours, many bits carved or marked.

These mountains have long been the stronghold of the Apaches. The Indian scouts have a tradition that this canon has evil men living in it. There are no recent signs of occupation by Apaches.

Dr. Burr seems to think that the quadrangles and the circles were to be attributed to different peoples and different dates. The circles, seemingly more recent, may have been built by the Apaches in ages past, or by people less advanced in civilisation than the first inhabitants. The small circles, about 3 feet in diameter, were ovens. They have a floor of flat stones well fitted, around which a wall is built up 8in. to 12in. There is no indication of a covering. Dr. Burr found here a stone mortar weighing about 100lb. The cavity is 4in. in diameter, and as many deep, perfectly round. It is conveniently located near the four ovens. On the hillside he also found another mortar that had been turned over, and two broken metates.

Near the mouth of the canon, and distant from camp about 6 miles, are some ruins not examined with care. They consist principally of quadrangles of small size, 15ft. by 20ft., and but few together. One group was at some distance from permanent water. There is a small ravine close by that now affords water in the wet season. This last group was on a high hill, and no agricultural ground was near, the ravine having precipitous banks. Other ruins are scattered along the banks of White River after it reaches the open plain outside the canon; but where they are placed no water is to be found in the dry season, it being at least two to five miles to the nearest permanent supply.

THE MECHANICAL ENGINEER'S OFFICE BOOK.*

MR. NELSON FOLEY, of Cardiff, late assistant-manager, Palmer's engine works, Jarrow, is the author of a very convenient form of office-book for mechanical engineers, the principal feature of which is the employment of diagrams for facilitating calculations. The application of diagrams for this purpose has become recognised of late years, and the use made of graphical modes of computation promises before long to revolutionise most of our textbooks. To the practical man, the diagrammatic form of table has decided advantages: he is enabled to obtain the result at once without the trouble of working out a difficult formula, and he can vary his known quantities without having to repeat a troublesome calculation every time. There is less risk of error also in using a diagram. Mr.

* The Mechanical Engineer's Office Book: Boiler Construction. By NELSON FOLEY, late Assistant manager Palmer's Engine Works, Jarrow. London: Crosby Lockwood and Co.

Foley has extended the usefulness of co-ordinate curves, and claims to be the first to design combined curves and to apply other devices to enable four or more quantities to be used. By the diagrams given, the designer of a boiler can easily see what thickness of plate will give the required percentage of strength at joint. The use of the diagrams is simple and self-evident. Diagram I., for instance, gives the Board of Trade rules for cylindrical boiler-shells, the strength of iron being taken at 47,000lb. per square inch. A series of rectangular lines, with curves diagonally drawn upon them, is the principal part of the diagram. The curves are figured at each end with the thickness of the plates, from 5-16ths of an inch to 1 1/4in. At the side are a series of scales for diameters for different factors of safety; and below is another series of scales for different percentages of strength at joint. When it is required to read the diagram, one edge of a set-square (for convenience) is placed at the proper diameter line on the left hand side, and the square moved till the right-angle corner touches the curve of proposed thickness of plate, then the vertical edge of square will pass through the scale with the pressure below at the required percentage at joint. Each diagram, of which there are 28 in the book, has a note explaining its use at the corner. These several diagrams relate to the Board of Trade rules for boilers of iron and steel, flat plates of iron and steel with different constants; girders, furnaces of iron and steel; after which follow Lloyd's rules for boiler-shells, flat plates, and furnaces, tables for riveting—giving the diameter, pitch, and length of rivets, and the consumption of fuel. Most of these tables are constructed of rectangular lines or ordinates and diagonal lines, and are very intelligible to the engineer. We may add that these diagrams are numbered, and the ledger-form of margin reference enables the consulter to refer to the table at one opening of the book; and the same system has been adopted in indexing the other matter. The letter-press gives a variety of practical information of everyday value to the engineer. The Board of Trade rules for boiler-shells are given, showing the factors of safety and the additions to be made under certain circumstances which are specified. But for cylindrical boilers made of the best material, with all rivet-holes drilled in place and all the seams fitted with double-butt straps and double riveted, and when the boilers have been open to inspection during their construction, 5 is the factor of safety. The boilers must be tested by hydraulic pressure to twice the working pressure and to the Board's surveyor's satisfaction. The memoranda on riveting are useful, and comprise every detail of boiler-construction, butt-straps, manholes, flat plates, stays, dished ends, girders for flat surfaces, circular furnaces and flues. Lloyd's rules for determining working pressure in new boilers are printed, and the chapter on riveting may be profitably consulted, and is full of useful formulae, tables, and examples. Speaking on this subject, the author says, "The diameter of a rivet must always be found before determining pitch, by assuming desirable percentages of strength at joint both for plate and rivets. The diameter being found, the pitch is arrived at by making use of the same percentage of plate section as was assumed." The tables of areas of small circles, of circumferences, areas, squares, and cubes, and weights of plate-iron, bars, boiler-tubes, &c., are very complete, and the book will be found to be an indispensable guide in the office or the factory of the mechanical engineer.

A CHIMNEYLESS LAMP.

THE use of paraffin lamps in country churches and other public buildings would have been more common by this time if chimneys and glasses could have been dispensed with as with gas. The *English Mechanic* describes a new lamp constructed on a totally different principle to that of any we have ever seen. The "Empress" lamp, as will be seen from the annexed illustration, is one of those which dispenses with a chimney, and yet, unlike others, it gives a white smokeless flame which is not affected by draughts. In the ordinary paraffin or kerosine lamp, the object of the chimney is to create a current of air, which aids combustion and produces the flame that gives the light with which we are familiar. The inventor of the "Empress" lamp, a Mr. Heyne,

of the United States, has taken a new departure, for instead of trying to create an artificial draught of air by chimneys or by plates deflecting the current on the flame, he fits the pedestal of his lamps with a clockwork movement driving a small fan at a high velocity. This fan draws in a current of air through the holes seen at the base of the pedestal and drives it out through the cone, thus supplying the place of a chimney in a more effective manner. The invention does more than that, for it robs paraffin lamps of the objection which has in certain quarters been strongly urged against them, by preventing all smell. The basin-shaped portion of the lamp seen in the illustration, is the top of the pedestal, and the reservoir of oil fits into it, being supported by the flanged rim. An air space is thus left all round the reservoir, through which a current of air is being constantly driven by the fan. The result

is that the oil in the reservoir is kept perfectly cool, and even the cone itself may be clasped while the flame is burning. Turned high or low, then, such a lamp evaporates no more oil than it consumes, and there is consequently a complete absence of smell, while the motion of the clockwork is heard only when specially listened for. Explosion with such a lamp is practically impossible. The flame of a 3in. wick is flat, almost perfectly white, and expands to a steady spread of about 3in., without any sign of flickering or waving even in the draughts of a room with open doors—in fact it cannot be easily blown out when turned fully up. The clockwork runs about 13 hours when fully wound, and in the lamp inspected by us the oil reservoir contains sufficient to last 8 hours. We have not tested the economy of the lamp; but inasmuch as there is no waste by evaporation and escape of unburnt gases, the consumption must be very low—the minimum, in fact, for a wick of the dimensions used. The clockwork is made to gauge, so that in the event of any part giving out or being damaged by accident, a duplicate can be at once supplied. To screen the eyes an opal reflector is used, supported slightly above the flame by means of a simple skeleton gallery. The lamp is especially recommended for those who read or work by night, for microscopists (it has been exhibited at the Royal Microscopical Society and the Royal Institution), and particularly for artists and others, who want an artificial light enabling them to distinguish colours in their true tints.

The town council of Yarmouth considered on Wednesday week alternative schemes for the drainage of the low-lying and thickly-populated district of Cobholm Island. The one was prepared by Mr. J. H. Bly, a member of the town council, who proposed to deal with the sewage by gravitation; the other was that of the assistant-surveyor, and proposed pumping, as the street-level was but 3ft. 4in. above low-water mark. After a long discussion, the latter plan was adopted: the estimated cost is £2,000.

A meeting of the subscribers to the Caxton Memorial Fund was held at St. Margaret's Vestry, Westminster, last week, when it was reported that £400 had been subscribed, more than enough to place a stained-glass window at the west end of one of the aisles of St. Margaret's church, but not enough by £200 to fill up one of the principal windows. It was decided to make a fresh effort to raise the balance.

Building Intelligence.

BRADFORD.—On Tuesday new scarlatina wards of the Bradford Fever Hospital were opened. The new section of the building has been in course of erection since September last. It is a double-storied building, and is substantially built throughout, the stone-dressing of the outer walls being of Idle stone, whilst the whole of the walls are lined with brick. The roof is of slate, and the entire building is well-lighted by six double windows in the front, with a large circular light at the top for lighting the staircase and corridors, in addition to which there are a number of side-lights. The entrance is in the centre of the front of the building, and the appearance inside is highly satisfactory. There are four wards on the ground-floor, two on each side of the entrance, and there are also four on the upper-floor. Each of these wards is 18ft. wide and 19ft. 6in. long, the height being 14ft., so that they will be very comfortable and airy. The ventilation is very perfect, Sherrington's patent ventilators having been used to secure an abundance of fresh air. The following have been the contractors for the various works:—S. Jackson, mason; Messrs. Toothill and Bamford, joiners and carpenters; Mr. Nelson, plumber; Mr. B. Dixon, plasterer; Mr. A. Nelson, slater; and Mr. D. Lynn, painter. Mr. Margerison has been clerk of the works. The cost of the new building is about £2,000, but in addition to this there is the expenditure necessitated by the furnishing of the wards.

GAINSBOROUGH.—On the 20th ult., the first stone of the new church of St. John the Divine, Gainsborough was laid. When completed, the church will consist of a nave six bays in length, with north and south aisles, a chancel of two bays, with north and south aisles and sanctuary; preparation is also made for a western tower. The vestries will stand at the east end of the north aisle of the chancel. The total length of the nave is 113ft., divided into six bays, with a width of 36ft. in the clear. The nave arcade is surmounted by a clerestory of two-light windows in each bay, the total height to the wall-plate being 51ft. The aisles of 33ft. in height, and 17ft. 6in. in width, are covered with a flat roof of 15th-century type: the nave with a pitched roof, boarded and panelled, with moulded ribs. The chancel and nave are of the same internal section, not separated by a chancel arch. The roof-truss, taking the place of the chancel arch, is more richly decorated than the trusses of the nave roof. The clerestory is continuous throughout the length of the church, of two-light windows, with tracery in the heads. The sill of east window is raised 27ft. above the floor-line, and has seven lights with flowing tracery in the heads. The total internal length of the church will be, without the tower, 169ft.:—viz., 113ft. in the nave and 56ft. in the chancel; the height, to the ridge of roof, internally, about 70ft. The columns, arcades, and all other stone-work are of Ancaster stone. A passage is arranged at the level of the clerestory string, 33ft. 9in. from the floor, to give access to the windows, this is also carried across the sill of the east windows. Externally the church is built of red brick with Ancaster dressings. The intermediate surfaces in the interior are plastered. The work now commenced consists of three bays of the nave, and the whole length of the chancel up to the clerestory string, the arcades being filled in with temporary walls. The builder is Mr. Johnson, of Doncaster. The architects are Mr. Somers Clarke, jun., and Mr. J. T. Micklethwaite, of 6, Delahay-street, S.W.

LEADENHALL MARKET.—On Tuesday was laid the corner-stone of the New Leadenhall Market. The new market and gangways will cover an area of about 26,900 square feet, and form the shape of a cross, the passage or gangway being 30ft. wide. The four entrances are:—West, from Gracechurch-street; north, from New-street to Leadenhall market; east, from Lime-street-passage; and south, from the side of the old gangway of Leadenhall Market through Beehive-passage. There will be 29 shops on the principal thoroughfares, the general principle of construction being somewhat allied to that of the poultry market. The basements are constructed for the storage of provisions. The cost has been estimated at £50,000. The principal entrance is in Gracechurch-street, and

will, with the other entrances, be kept always open and free from any gates whatever.

NEW BRIGHTON.—The foundation-stone of a New Roman Catholic Church, at New Brighton, was laid in September last. To Mr. Edmund Kirby was confided the work of designing the building. The church, in which accommodation is provided for from 350 to 400 persons, is arranged with a nave and gallery, whilst at the east end are the chancel, a transept, and a sacristy. Early English is the order of architecture which has been followed in the execution of the design. Mr. William Owen, of Liverpool, is the contractor. The church was opened on Wednesday.

PECKHAM.—The foundation-stone of the new Unitarian Chapel, Avondale-road, Peckham, S.E., was laid by Sir James C. Lawrence, Bart., M.P., on Tuesday, the 23rd ult. The style adopted by the architect, Mr. Henry G. Brace, A.R.I.B.A., of Chancery-lane, is Early English, and will be of red brick and stone dressings externally. The chapel will hold 250 persons on the floor-level, and 50 in the gallery. Internally the facing will be of Luton brick with red bands and open-timber roof. After the ceremony above stated, the school-room just completed, in connection with the chapel, was formally opened. The room is 33ft. by 50ft., with stock brick facio and red bands internally, the roof being partly open. The builders of the chapel are Messrs. Hoare and Son; and of the school Messrs. Watson and Dennett.

TOLLINGTON PARK, N.—The inauguration ceremony upon entering the new buildings for the collegiate school recently erected, at the cost of Mr. R. Wells, for the principal, Mr. W. Brown, B.A., F.R.G.S., took place last Tuesday evening, under the presidency of Mr. T. L. Roberts, barrister. The new schoolroom (which is on the first floor) has been built upon the site of stables and coachhouses, which were connected with the houses on either side, and is 62ft. long by 29ft. wide, and 23ft. from floor to apex of roof, with communications on each side to adjoining houses, the one at entrance being the residence of the principal, the other house being devoted to the use of the masters and boarders, and the ground floor is arranged as class-rooms, connecting with the schoolroom. The roof is of composite construction, having wrought-iron trusses, with fir wrought purlins and ridge, covered with wrought V-jointed boarding, roofing-felt, and is slated. The lower portion of walls are protected with wrought and beaded dado, 5ft. high, with moulded capping. The room is lighted by twelve windows, which have double-hung sashes, those at north end having additional sashes hinged, and with quadrant stays. The floor, which is also composite, is carried by rolled iron girders resting on piers built in cement, with buttresses on outside of wall, and by cast-iron columns in centre of each girder. At the west end of room a platform is constructed to receive the organ; also for the use of pupils during examinations. The ironwork was supplied by Messrs. Measures Brothers. Every consideration has been given to ventilation, which is by inlets from below the floor, and opening into the room at dado-level; also to the artificial lighting, for which two sunlights are provided, and as a medium for extracting vitiated air. The space immediately under the schoolroom is devoted, as a cloister, for the use of pupils during hot weather. At the north end, and communicating with the schoolroom, is the cloak-room, forming also the pupils' entrance, and adjoining which are the w.c.'s, planned so as to be easily accessible and under cover. The sanitary system is so arranged that no sewer-gas can enter the premises, and is well ventilated with vertical tubes, all surface-water emptying into interceptors. The playground is laid with tar-paving. The walls of schoolroom are faced externally with picked stocks. The front elevation, which is of a Queen Anne character, is built of stocks, relieved with red brick dressings, with terra-cotta balustrade and capping. The entrance and light to cloisters is provided with wrought-iron gate and grill. The works have been carried out by Mr. Harold, from the designs and under the superintendence of Mr. F. H. Stringer, the time occupied being about eleven weeks.

WICKERSLEY.—On Tuesday the church of St. Alban, Wickersley, after undergoing renovation, was reopened. There was a church in the

parish at a very early period, doubtless of Saxon origin. The present church is a stone Gothic building, consisting of chancel, nave, embattled tower, and three bells. The old pews have been removed and replaced with open benches of pitch-pine. The unsightly gallery at the west-end has been taken away, and the tower-arch has been opened out. New pulpit, lectern, choir stalls, and Communion-rails have been provided. The organ has been repaired, and the case and pipes have been redecorated. The wood from the old seats has been utilised as a dado round the walls. The works have been carried out by Mr. E. I. Hubbard, architect, Moorgate, Rotherham; and Mr. Wm. Earnshaw, of Treeton, was contractor.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

BIRMINGHAM AND MIDLAND INSTITUTE.—On Saturday about fifty members of the Archaeological section of the Birmingham and Midland Institute left Snow Hill by train for Stourbridge, and began the programme with luncheon at "The Talbot," an interesting old inn, retaining a part of its galleried courtyard, some rooms with oak-panelled walls and carved chimney-pieces, and a good staircase, all probably of the early part of the last century. The party then visited Kinver Church, the appearance of which as approached from the south-east is pleasing, the long south aisle, with its steep tiled roof and row of traceried windows, having a striking effect. The continuous ridges of the roofs are happily broken by the picturesque tower, and the stone being of a soft reddish brown, it stands out with fine effect from a background of rich foliage. It is as yet unrestored; there is, nevertheless, on the north side a modern aisle, to make room for which the wall of the Norman nave was pulled down, leaving only the two western flat buttresses and a bit of string-course to mark the previous existence of a church of the twelfth century. The south aisle and arcade and the tower are of the 11th, and the chancel, with north and south chapels, of the 15th centuries. The north or Foley chapel is of Tudor character; in it lies a mutilated effigy of a knight, one of the Hamptons; in the south chapel is a fine tomb of Purbeck marble, on which are embedded somewhat rudely-engraved "brasses" of Sir Edward Grey, son and heir of Humphrey Grey, 1528, and his two wives, the second wife with small groups of effigies of her seven sons and ten daughters, and a marginal inscription. Among the curiosities of the church are three old volumes, and the oak desk to which they were once chained, and a framed charter, with seal of King Charles II. The windows contain many interesting fragments of stained glass, and some valuable detached pieces of heraldic glass of Early 15th-century date have been saved from destruction by the vicar. The font and pulpit are both good examples of their periods, the first of the 15th and the latter of the 17th centuries. The Rev. J. Hodgson, the vicar, having recounted the history of the fabric, its endowments, and its many historical associations, the party walked to the camp on Kinver Edge. Whatever was its origin, the camp was occupied by the Saxon King of the Mercians, Wulfhere, son of the terrible pagan King Penda; and here he held a position in his rebellion against Oswy. The banks are still in good condition, and it is believed that the camp was kept up and occasionally occupied during the middle ages, until as late as the time of Henry IV.

Shropps Park, on the north side of Halifax, was opened by the corporation on Thursday. It is 25 acres in extent, and is planted with about 60,000 trees and shrubs; amongst the alterations are a drive, surrounding the grounds, a drinking-fountain, a summer-house, and a cascade of water carried over a cliff into pools below. The cost has been £11,000, of which £2,000 was borne by Col. Ackroyd, and the remainder by the corporation; the site has been leased for 999 years, at a nominal rent, of Mr. H. Saville, of Rufford Abbey.

The board of Breamford, at their last meeting, decided to retain the services of Mr. Figg, the late surveyor, as consulting engineer for three months, and voted him the sum of £50 as remuneration for that period.

"To a practical man with a taste for mechanics, and the bumps of constructiveness fairly well developed, we can give no higher mental treat than a couple of hours spent over the June numbers of that truly marvellous publication the *English Mechanic*. In a hundred and fifty odd pages that make up the bulky mass of letterpress, there is recondite information on almost every conceivable subject, ranging from how to construct a mouse trap, to the latest method of calculating the phases of Orion"—*The Englishman*. Price Two-pence of all newsmen, or post free 2½d.—31, Tavistock street, Covent garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.
Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is ONE SHILLING for TWENTY WORDS, and SIXPENCE for every eighth word after. All Situation advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in serial advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33s. 30c.). To India (via Brindisi), £1 10s. 10d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

Mr. CHARLES WILSON, of 13 and 15, Laight-street, New York City, is authorised to receive American subscriptions at the rate of 6 dols. 40c. per annum.

Mr. R. M. TUTTLE, of Titusville, Penn., U.S.A., is also authorised to receive subscriptions at the same rate.

Cases for binding the half-yearly volumes, 2s. each.

NOTICE.

With this number commences Vol. XLII. The title and index to Vol. XL, completed in the last issue, will be published next week, July 8, and bound volumes and cases will be ready shortly after.

N.B.—Bound volumes of Vol. XL should be ordered at once (price Twelve Shillings), as only a limited number are done up. A few bound volumes of Vol. XXXIX. may still be had, price Twelve Shillings; all the other volumes are out of print. Most of the back numbers of former volumes are, however, to be had. Subscribers requiring any back numbers to complete Vol. just ended should order at once, as many of them soon run out of print.

RECEIVED.—M. and B.—P. and S.—T. E.—J. H.—S. Bros.—H. B. and T. Co.—J. T.—R. S. and Co., Ltd.—W. S. and S.—J. C. and Co.—H. C. C.—T. P. F.—F. R. K.—Rev. E. A. W.—C. R. F. L.—N. C.—J. W.—J. H.—G. B. and L.—J. S.

YOUNG ARCHITECT. (House agents are generally appraisers also, and have to take out licences; but any architect can advertise houses to let without a licence. It is not necessary that an architect should have a valuer's licence; many make valuations without, but valuations required for arbitration purposes can only legally be made by licensed valuers. If an architect intends to make valuation a feature of his business, we should certainly recommend him to take out a licence.)

Correspondence.

COMPETITIONS.

To the Editor of the BUILDING NEWS.

SIR,—Taking in your paper every week, and which I have done for now nearly three years, I have certainly been amused at the frequent outbursts of indignation against competition.

I myself have been, and still hope to be, a competitor; but, standing entirely on neutral grounds, I am fully persuaded that no good will accrue as long as your correspondents entertain the spirit which, it seems to me, runs through the mass of letters on this subject, a spirit of "the dog in the manger"—they do not want to compete themselves, and yet they object to others doing so.

The fact is, Sir, the profession is doing itself an injury by these jealous epistles. Take four cases only, and in the half-year: on Feb. 4th, architects are requested to decline competing on any terms whatever; on March 11th, "Yankee Doodle" writes a sarcastic letter, headed "A

Practical Young Architect"; on May 27th a request is made to close the advertisement columns of the BUILDING NEWS against competitions; and on June 24th (last Saturday) a letter appears, re Wincheombe School, in which it appears a county surveyor figures amongst the competitors, "and, indeed, he appears to be the successful competitor."

Now, Sir, underlying all these letters is a nasty feeling, which it must be plain to anyone brings the profession into derision. If a county surveyor or a young amateur both by their own intelligence succeed in winning a competition, all honour to them; surely England is big enough to contain all its architects, barring, however, one section—viz., the jealous-disposed, whom I should advise to settle in the islands of the Pacific, one in each, and where they can design and build without fear.

But about the competitions themselves. I know a reform is needed; but surely, Sir, the men who have got the sense, or rather non-sense, to write you correspondence complaining of this and that, surely have the sense to be able to understand the conditions of a competition, which if not satisfactory to them it is their fault if they enter it and if they are hurt, follow the example of a little child when it says "I'll tell ma." Competitions in my opinion are admirable things when conducted properly—they bring out the powers of men who otherwise could not show them, and they give everyone a fair chance of success. But in reference to those that are not conducted properly, the best and certainly most exalted method is to pass them by, and not—which is the main point of my letter—squabble over them in a paper. Pass over them, and let those compete who will; but in very love of this noble profession I appeal to all its members to stay this paper warfare, which is doing a silent but sure mischief.—I am, &c.,

A BELIEVER IN HONEST COMPETITION.

BUILDING-STONES.

SIR,—The only thing I can see in the recent correspondence on this subject is a lavish eulogium on the quality of Beer stone as a building material; a Bath and a Caen-stone merchant claim their stones to be equal, or superior, to Beer.

One might let the matter rest here, were it not that Mr. Masey, in his zeal, states that "Beer stone is better than many (*i.e.*, building-stones), and equal to any, for external purposes."

I think he has left out the little words, "at the price." Surely he does not intend to say that Beer stone, which is only one remove from chalk, is equal in durability to Aucaaster, Bramley Fall, Portland, Craigleith, Cullif, Corsehill, Grinshill, Hollington, Horsley Castle, Howley Park, Finsdale, Hayshaw Moor, Shepley, Seotgate, Seotgate Head, Spinkwell, Wild Carr, and a host of other well-known weather-stones, all of which are not used so largely as they ought to be for external purposes in consequence of cost.

A graphic history of any of them would be interesting, or a pilgrimage to the quarries, and the abbeys and mansions near thereto, would be a delightful trip.

Internal Work.—For internal work there is no stone equal for warmth and richness of colour to the Aucaaster and Caen stones. Forty years ago I lined two large buildings internally with Aucaaster, both of which are as good to-day as when first put up. Aucaaster stands equally well externally—evidence the Lincolnshire churches. Not so Caen. This is only good for internal work. Mr. Masey tells us Buckingham Palace was built of Bath stone. I think he will find it was built of Caen stone.

Bath.—There are many buildings in London built of carefully-selected Bath stone, which stand exceedingly well. The Grosvenor Hotel, Victoria Station, is one. This is built out of selected Corsham. Nevertheless, I could point to numbers of failures where Bath stone had been used in London, especially during the last three winters; but deprecating one stone does not make another the better.

Colour.—Colour is a large element in the choice of stone for façades of buildings; hence the present use of coloured stones and red brick.

I venture to think that few gentlemen, after examining the colour of Beer stone in work, will become enamoured thereof. An instance in London may be seen at the corner of Brook-

street, Holborn, in a recently-erected building, the dressings of which are out of Beer stone: the appearance of the stone now is like that of dirty chalk.

Some of my friends and myself tried Beer stone some years ago; but the colour in work we found an objection, although the cost of labour is in favour of Beer stone.

"A Mason" has a practical way of looking at the matter when he states that a glowing description might be made of a visit to many other quarries.

Many of us remember Harry Hems' graphic description of a visit to the Beer stone-quarries published in your journal some months ago, of which it may be said that Mr. Masey's looks like a second edition, save that those of us who know Harry Hems, know also that he will not affirm Beer stone to be a thorough weather stone, or in this respect to be "equal to any."

At the same time it is a sign of progress when professional gentlemen visit and inspect stone-quarries for themselves: all interested in the use of durable stones must heartily wish they would largely extend their visits to stone-producing districts. I can promise them a glad welcome from many.—I am, &c.,

SAMUEL TRICKETT.

Sir,—We did not notice the letter by "Durability,"—appearing in your issue of the 17th inst.—until too late to reply in time for your last publication.

It was with great astonishment that we perused the statement contained therein with reference to Box Ground stone, it being quite inconsistent with the character of this stone.

Our experience, in point of time, is considerably more than double that of "Durability," and, counting it by the number of buildings with which we have been connected, in which Bath stone has been used, must be far greater than his can possibly have been.

The experience we have gained of Bath stone generally—in consequence of the position we hold for supplying parties in the trade—is necessarily very extended; and we have, too, the great advantage of receiving a continual flow of independent testimony from those by whom the stone has been used.

The experience thus obtained, with reference to "Box Ground" is—that it is a weather-stone of great merit and undoubted repute for durability in the most trying situations.—We are &c.,

PICTOR AND SONS.

Box, June 29.

Sir,—Having been connected with the building trade and the use of stones, including Bath stone in particular, in all parts of the country under some of the most eminent architects for upwards of 30 years, and having used a vast quantity of "Box-ground" in particular, I think it only due to the public generally to state that my experience of "Box-ground" is quite the reverse of that of "Durability." My experience is that "Box-ground," of all oolites, is the very best as a weather-stone, and I would advise architects, or any one about to use Bath stone, to make their own inquiries, which I feel confident will confirm my own experience of this stone.

I quite agree with "Durability's" remarks as to the injurious practice of leaving the cleaning down of the building until the conclusion of the work, and I think it is important that the stone should be completed on the banker, so that the case-hardening process, which commences after fixing, should not be disturbed.—I am, &c.,

FAIR PLAY.

Sir,—Mr. Sumson perverts my meaning. Permit me to say that I cast no reflection on the statements of Mr. Kirkaldy—a gentleman I much respect. No one, I am sure, could take more pains and care than he does. My doubt was in respect of the specimens being representative of a quarry. It is not agreeable to common-sense to suppose that Mr. Sumson's quarry is so different to all the rest of the oolitic deposit. There is a hard bed, I know.

It is a base assumption that I have any other than a professional interest in the matter.

I can adduce no other than the St. Stephen's Chapel instance of Beer stone in London, for the simple reason that the great fire of London effaced all medieval work, and since then the stone has not been used here, and but little elsewhere, the quarries being out of the way. A seaside specimen can be

seen at Charmouth, built, I believe, about thirty years, and in excellent condition.

As I spoke in reference particularly to city endurance, the specimens quoted by Mr. S. of old buildings are not admissible.—I am, &c.,

PHILIP E. MASEY.

21, Old Bond-street, W., June 23th.

BUILDER AND ARCHITECT.

Sir,—"Bear's Heart" need not feel discomforted because he has not been article'd, or never worked for an hour in the office of a professed architect. I know a dozen men who have never enjoyed these so-called privileges, but who yet are good architects, some doing a large business. An architect, "architect-builder," and "builder-architect," are merely conventional expressions, and signify really nothing more than that some architects busy themselves more with building than others. Why not, it may be fairly asked, is not building the legitimate field of the architect's artistic labour? Of course there are, as in other things, architects and architects—some who can design, others who cannot; some who devote their time to artistic designing, and others who practise only as architects. There is no royal road. It is really what a man can make of himself, whether he be architect or anything else. Artisanship without ability counts for little.—I am, &c.,

ARCHITECTUS.

CONSTANT SUPPLY OF WATER TO LONDON.

Sir,—Noticing with great pleasure your great kindness in allowing your valuable paper to become the medium for calling public attention to various necessary improvements and requirements, I have ventured to place the following remarks before you on the above subject for publication.

It is now some years since public attention was first called to the necessity existing for a good and constant supply of water to London. Great interest was at first evinced; scientific men, medical and otherwise, entered energetically into the question. The Metropolitan Act of 1871 was an important result, although strenuously opposed by the several water companies; its aim was to solve the difficulty existing between the public and the water companies. Certain regulations were made describing the necessary fittings and method of supply to houses; copies of these "in an abstract form" were made and printed for distribution by the water companies, and everything seemed to point to a speedy and universal unanimity of purpose. A constant supply was the prevailing theme. The late Government entered into the question, but in such an incomplete manner that dissatisfaction was the result, and it soon became evident that the public and the water companies would never become reconciled by "Cross" purposes, and so although a constant supply has been given to small sections of London and its suburbs, yet it is far from being what it ought to be—viz., "universal." Now, no doubt, to many persons the question arises, Why is this the case? It may arise from two causes—Firstly, the indifference of the several water companies to anything except securing good dividends to their shareholders, and secondly, the ignorance of some of their engineers as to the working of, and the advantages derivable from, a constant supply. The indifference of the companies, even under the present system, is shown by the state of cisterns containing the daily supply of water. Covers wanting, full of weeds and dirt, even used as baths by the small boys of the house—this is, I am happy to say, very exceptional—and nearly always allowed to be placed over w.c.'s ready to absorb all noxious gases, all which defects could be remedied if the companies chose to exert themselves, and use their legal powers. This description is not a fancy sketch, as anyone travelling by the railway lines which overlook the back-yards or gardens (:) by which they pass can verify by ocular demonstration. This state of things is a disgrace. As regards the engineers, some of them have shown a laudable desire to do away with this state of things; but even they seem to lose energy when they see the increasing coolness of their directors as to the constant supply: of course they have their own interest to study, and I am sorry to see it made the ruler. An engineer (if he can honestly claim the title), should be fearless in expressing his opinion and in carrying out his works, and not be swayed by directors, who, if they understood the question as they ought to, would be only too glad to hear and uphold their engineer when he laid before them an expanded and practical view of the subject. If Watt, Stevenson, Brunel, &c., had not been men of determination, where would the commerce of the world be? And but for the same trait in Sir Hugh Myddelton's character, where would water companies be? This is, however, a digression. In calling attention to what I consider ought to prove an inducement to the companies to make the constant supply universal, I would refer to the very great superiority in the

designs of the various fittings—viz., taps, ball-valves, waste-preventers for w.c.'s, in w.c.'s themselves, detectors of waste, &c., &c., necessary for providing houses with a constant supply, and if fitted as laid out, and directed by the Act, the storage of water in imperfectly-covered and objectionably-placed cisterns for drinking purposes would become an abomination of the past. An arrangement of supply to a house may be as follows: A lead pipe when size is determined (the regulations obtainable at any of the companies' offices, according to which gives the supply of water, will show the necessary weight, &c.,) coming direct from the company's main, fitted with screw-down stop-cock near entrance, and continued through the house to upper cisterns, with ball-valve, &c.; on this pipe are to be fixed, "as may be required," one or more screw-down draw-off taps for obtaining the water for drinking purposes direct from the company's main. The upper cistern, with necessary fittings, cover, &c., to be placed at such an elevation as shall be necessary for the required supplies. (If hot-water is required, it is best to have a separate cistern, which can be supplied by a branch from the pipe referred to.) The down-pipe from cistern, supplying bath, and the different waste-preventers in the several w.c.'s, can be continued from the supply to lowest w.c., and to the scullery, or other sink, and have a draw-off tap put on it, thus making the cistern available as a reserve for domestic and sanitary purposes should an accident occur requiring a suspension in the supply. The continuation of the pipe from last w.c. to sink has been objected to, as the water was liable, by not being drawn off regularly, to become impregnated with lead, and so become dangerous to health; but as this chemical action does not take place in a few hours, and as a tap over an ordinary sink in the scullery is seldom long unused, I venture to think the objection may be put on one side. Should, however, this be made an obstacle to having a reserve, another simple plan might be adopted. Let a wrought-iron cylinder, water-tight, with only holes with unions for inlet and outlet pipes capable of withstanding the co.'s pressure, be fixed in a vertical position, where most convenient (it should have capacity sufficient, say, for 30 gallons), and supplied by a branch-pipe from the main-pipe in the house, with a proper joint where connected to cylinder at top, and also again where draw-off pipe and tap are fixed at bottom. A valve opening inwards must be fixed on top of cylinder; this will be kept close when pressure is on, but when the pressure is removed by Company's main being shut back, &c., it will open, and allow the contents of the cylinder to be withdrawn. A manhole in the side, having door and proper joint made, would admit, by its removal, the cleansing of the cylinder, which would be about once in three years; here is a reserve without the nuisance of ball-valve or chance of contamination. All cisterns should be well covered and placed so as to admit of their being easily cleaned and examined. I would also impress upon architects the desirability of making the proper positions of pipes, cisterns, and w.c. part of their original plans, and not, as is too often the case, "after-thoughts" to be placed where convenient; not only does the water supply require protection, "especially during frost," but sanitary considerations demand its attention. By the before-mentioned arrangements, as good water as it is possible for the companies to deliver can be drunk without fear of contamination from sewer exhalations, &c., and would always be fresh, cool, and unlimited in quantity. The cistern is, to the companies, as the "old man of the sea," hard to shake off. As regards the quality of the fittings, if the companies would insist on the materials and workmanship being first-class, those makers who sacrifice reputation to cheapness would be compelled to come up to the standard, and not only would the companies gain, but the trade would generally assume a healthful and substantial tone. This improvement in the fittings combined with the simplification of the method of laying on the water, would materially reduce the waste of water. The constant supply also acts as a preventive of waste by causing annoyance from a dripping or leaky tap, or an impromptu shower-bath from cistern overflow, due to defective ball-valve, &c., the annoyance from such causing the most careless to have repairs done, and be careful in future not to abuse the fittings, or hold in contempt the power behind them. The removal of the extra cistern will be a source of gain to the companies, as there is emptying of cistern to obtain a fresh supply (the general idea of cleansing). Yet it is really waste of water. Although useful in flushing the drains, it is not the legitimate purpose for which it was delivered. This, I think, conclusively proves that the companies stand in a great measure in their own light by withholding a constant supply. I trust my remarks may again call Government attention to the subject, and not leave us to imagine that the Irish Land Bill has completely imbibed the moisture from the Water Bill. I am sure honourable mem-

case, Dalton having been the contractor employed by the Commissioners.—HUGH McCLACHLAN.

[6547].—**Measuring Up.**—The following is from Hurst's "Architectural Surveyor's Handbook":—"The charge for measuring works in small new buildings and in repairs, including a bill of the particulars is 2½ per cent. For large new works of plain character the usual charge is 1½ per cent. When the works are of elaborate construction the charge will vary from 1½ per cent. upwards, according to the additional trouble entailed in measuring." Surveyors vary much in their charges, from 1½ to 2½ per cent. being charged by experienced men for the same class of work, 2 per cent. is also very usual; this I believe arises from there being no recognised scale, as is to be found in the architectural profession.—HUGH McCLACHLAN.

[6549].—**Portland Cement Mouldings and Flat Surfaces.**—Thoroughly saturate with water the surface of cement-work before applying the finishing coat so as to remove all irregular suction. The finishing coat to be of same proportions sand and cement as preceding coats, only the sand to be of a finer grain. Apply as much as can be safely finished before it gets too dry for floating. Float with wooden float until the glazed and watery appearance leaves the face of the work, which will come out a nice and uniform colour if carefully done. Mouldings: After getting the moulding as full as the mould, let it stand until hard. Apply water same as preceding. Mix fine sand and cement, same proportions as surface finish, and keep part of it dry. Give the moulding a coat of fine stuff, gauged very soft, then pass the mould across it, keeping it very tight. Take the cement and sand that you have kept dry, and damp it sufficient to make it bind together. Throw it all over the moulding (be sure that it is all covered), run the mould across it quite slack, so as it will not take off all the dry stuff. With practice you will make it come out the same colour as the plain surface. I hope this will suit "Stone Finish."—PLASTERER.

[6550].—**Egg-Shell Polish for Antique Furniture.**—This is done by first bodying up your work the same as before directed, and, after standing twelve hours, again body up with white polish. It is then rubbed down with a felt rubber and pumice-stone until sufficiently dull. It is then wax-polished, giving the work a gloss instead of a polish. Dry shining is a new system of polishing or shining called the American system, and is used mostly for American black walnut. First oil, fill in then with a wet rubber passed smartly over the work straight from end to end until a shine or gloss appears. No oil to be used in the rubber, and no spiriting off is required. Be careful to dry rubber well, and have the work free from rubber marks. This system is becoming very popular in the trade.—C. W. S.

CHIPS.

The Cambridge Improvement Commissioners recently wrote to the Local Government Board, asking if that authority would be likely to sanction the adoption at Cambridge of a sewerage scheme similar to that in operation at Coventry. At the last meeting of the commissioners a reply was read from the Local Government Board, informing them that, while it was not the usual practice of the Board to express any opinion as to a scheme until plans and details were submitted, they would, in this instance, state that the Coventry system could not be recommended as the best for the disposal of the sewage of Cambridge. On the contrary, the Board were advised that it could best be dealt with by a system of broad irrigation over land, or intermittent filtration through land.

The Brecon town council inspected, on Wednesday week, the system of sewers and sewage-tanks and works which have just been completed in that town.

A brass eagle lectern has just been placed in the pro-Cathedral, Liverpool, and it is a fine example of ecclesiastical brass-work, and reflects credit upon Messrs. T. Potter and Sons, of South Molton-street, London, by whom it was executed. It stands about 8ft. high, and the book is supported by three massive feet of brass, with a lion crouching at the base of each; and, immediately under the globe are three finely-executed figures of angels, with their wings outspread. Round the base of the lectern, and also in the Bible which accompanies the gift, is an inscription.

Christ Church, Blakenhall, was reopened on Wednesday week, after the addition of a tower with pinnacles of stone, like the other part of the edifice. The enlargement of the structure was done by Messrs. Barker and Sons, contractors, Handsworth, from the designs of Mr. Naden, architect, Birmingham, and the internal renovations were carried out by Mr. Fryer, of Bloxwich.

Extensive alterations and additions are about to be made to a Primitive Methodist Chapel at Noland, near Halifax, from the plans of Mr. Thomas Firth, architect, of Elland.

The Plumstead district board of works, at their last meeting, accepted the resignation of Mr. T. C. Haworth, surveyor of Eltham, tendered, after 26 years' service, on account of advancing years, and granted Mr. Haworth a retiring allowance of £60 per annum; it was resolved to offer the salary of £150 a year to the successful candidate for the appointment. At the same meeting Mr. E. L. Rumble was elected surveyor for Plumstead parish in succession to Mr. Thorne, resigned.

PARLIAMENTARY NOTES.

RAILWAY EXTENSION TO RICKMANSWORTH.—A Select Committee of the House of Lords on Wednesday passed a Bill, which has already received the sanction of the House of Commons, authorising the construction of a line from the Uxbridge branch of the Great Western Railway to join the Watford and Rickmansworth Railway to Rickmansworth, a distance of over eight miles. The line will be constructed by an independent company, who have powers to raise capital to the extent of £150,000, and to borrow any sums not exceeding £50,000. The cost of construction is estimated at £114,425, which provides for the erection of stations at Uxbridge, Denham, and Harefield, and for enlarging or building a new station at Rickmansworth.

LEGAL INTELLIGENCE.

LOCAL BOARDS AND CONTRACTORS.—**FLETCHER v. HUDSON.**—This case, tried in the Court of Appeal on Tuesday, before Lords Justices Bramwell, Brett, and Cotton, raised a question of some interest, especially to members of Local Boards—namely, whether, if a member does an act—as taking a contract with his Board—which is declared to vacate his seat, he is also liable to a penalty imposed on a member acting when disabled from acting. It was an action against a member of the Local Board of Grasmere, in Westmoreland, to recover from him a penalty of £50 for acting as member when disabled by such a contract. It appeared that there were several contracts between the member sued and the Board (for work to be done by him in carting materials for roads), the contracts extending from March, 1877, to March, 1878, under which payment was made to him on the 6th of March, 1879: and on that day he sat and voted as a member of the Board. He was sued for the penalty, and at the trial, at the Assizes at Appleby, the Judge (Mr. Justice Stephen) held him liable. This was an appeal by the defendant from that judgment. There was also, besides the main point, another objection to the action that the plaintiff is not a "party grieved," and that the action was not sanctioned by the Attorney-General. By the Act of 1875, section 61, any member who accepts or holds any office or place of profit under the Board, or in any manner concerned in any bargain or contract entered into by the Board, or participates in the profits thereof or of any work done under the Act, shall cease to be a member and his office shall become vacant. Section 65 says that any casual vacancy occurring by disqualification or otherwise shall be filled up; and then section 70 says, "Any person who not being duly qualified to act as member, or not having made the declaration required by the Act, or being disabled from acting by any provision of the Act, acts as member, shall incur a penalty of £50." Sir J. Holker and Mr. Crompton, for the defendant, who appealed, argued that he was only temporarily "disabled" during the continuance of the contract, and not afterwards, or at the time he sat and voted: that he was not disqualified, though his office was vacated, for he might be reinstated; and therefore he was not liable to the penalty, not being "disabled" when he sat and voted, though as his seat was vacated he was not a member. The statute contemplated the case of a member disabled from acting while still remaining a member, whereas here he had ceased to be a member and was a mere stranger. Lord Justice Brett observed upon this that it would be strange if a member acting wrongfully when legally disabled from acting was liable to the penalty, and a mere stranger sitting and acting not liable. Lord Justice Bramwell put the case of a mere stranger intruding into the House of Commons and sitting and voting. Would he be liable to the penalty for sitting and voting without taking the oaths, &c.? The House, of course, would turn him out, and so could the Board in such a case as the present. Mr. Charles, Q.C., with Mr. Addison, Q.C., argued for the plaintiff that the action was maintainable, and that there never was a case more clearly within the mischief met by the Act, and it would be a strange construction of the Act to hold that the case was not within the Act. Mr. Crompton having been heard in reply, the Lords Justices conferred together, and then said they would take time to consider their judgment, but that both the parties would do well to agree to a *set process*.

STAINED GLASS.

ALL SAINTS' CHURCH, SOUTHPORT.—Three stained-glass windows have been erected in this church. The central four-light east window is an illustration of the "Te Deum," containing groups of figures representing the angels, apostles, prophets, martyrs, and the Holy Church. The principal tracery contains a figure of Our Lord seated in majesty, and the smaller traceries, the four archangels, and groups of cherubim and seraphim. This window is flanked on either side by a two-light

window: that to the north contains, beneath rich canopies, figures of SS. Matthew and Mark, and the tracery above a seated group of "Faith, Hope, and Charity." The window on the south side has figures of the other two Evangelists, SS. Luke and John, and in the tracery is another seated group, representing "Temperance, Justice, and Fortitude." The border to these windows shows a conventional rendering of the Vine, through which, clad in white, are small delicately-drawn angels, bearing the various emblems of Our Lord's Passion. The windows were designed and executed by Messrs. Shrigley and Hunt, of John o'Gaunt's Gate, Lancaster, and 28, John-street, Bedford-row, London.

BARTON-ON-IRWELL CHURCH, NEAR MANCHESTER.—A rich medallion stained-glass window, in the Early English style (in character with the architecture), has been erected in this church. The subject illustrated is the "Parable of the Sower," the principal figure occupying the central medallion, and in the upper and lower medallions are subjects—"The End of the World, with the Reaping Angels," and the "Euemy Sowing Tares while the Husbandmen Sleep." The window is full and rich in colour, much in the manner of the celebrated Canterbury glass. The window was designed and executed by Messrs. Shrigley and Hunt, John o'Gaunt's Gate, Lancaster, and 28, John-street, Bedford-row, London.

STATUES, MEMORIALS, &c.

BRIGHTON.—A memorial has just been erected in the Extra-Mural Cemetery, over the grave of the late Mr. Albert Creak, M.A., Principal of Wick House School. The design is by Mr. Arthur Cawston, of Clement's-lane, London. It consists of a massive cross, with the sacred monogram at the intersection of the arms, supported by a moulded base, on which is the text, "In Thy light we shall see light," beneath which is the inscription. The monument is in Carrara marble, and has been executed by Messrs. B. and W. Bennett, of Brighton.

WATER SUPPLY AND SANITARY MATTERS.

GOOLE, YORKSHIRE.—This town is about to be supplied with water by the New Gas and Water Company, the Bill having passed. Mr. E. C. Buchanan Tudor, C.E., the town surveyor, has completed his scheme for the remaining portion of Old Goole, and tenders are being invited for the works, which are to be commenced immediately.

CHIPS.

A free public library was opened at Richmond, Surrey, on Saturday week. The building is Gothic in character, and has cost £2,000; Mr. J. S. Brunton, of Richmond, was the architect, and Mr. J. J. Osborne, of Turnham-green, the contractor.

A scheme of sewage is about to be carried out for the Brownhills local board, the works including the laying of 5,000 yards of stoneware pipes varying from 6in. to 15in. in diameter, and 600 yards of 12in. iron pipes. The engineer is Mr. J. H. Shipway, of Colmore-row, Birmingham.

At a meeting held at Newport, Mon., on Thursday week, plans prepared by Mr. Fawcner, architect of that town, were adopted for the enlargement of the infirmary and dispensary by 20 additional beds, and the widening of staircase and doors and other works.

New premises were opened last week by the Yorkshire C. and C. Bank in High-street, Doncaster. They have been refitted and altered by Mr. William Anelay, of Doncaster; the architect was Mr. J. Demaine, of York; and Messrs. Maw and Son carried out the decorations.

At the annual diocesan conference held on Tuesday week, the following grants towards increase or improvement of church-accommodation were made:—In Ely archdeaconry: restoration of Barton church, £60; mission-room at St. Andrew the Less, Cambridge, £10. Sudbury archdeaconry: Glemsford mission-room, £20. Bedford archdeaconry: restoration of Eggington Church, £30; of Toddington Church (renewed), total cost £1,200; £10; of Thurleigh Church, £25; and New chancel, Christ Church, Luton, £40.

An exhibition of sanitary and labour-saving appliances will be held in the Ironmasters' Exchange Hall, Wolverhampton, in August next.

The memorial to Earl Beaconsfield, to be erected by the City of London Lands Committee in the Guildhall, has been intrusted to Mr. R. C. Belt, and the bust of Earl Russell, to be placed in the same building, will be executed by Mr. C. B. Birch, A.R.A.

Our Office Table.

A SPECIAL meeting of the Metropolitan District Railway Company was held on Monday, to consider a Bill authorising the making of a railway from the London and South-Western Railway Company's station at Surbiton to the Fulham extension terminus of the district system. The Bill, which has passed the House of Commons, and is now in committee of the House of Lords, is the outcome of the more ambitious project, the Guildford, Kingston and Fulham scheme, of which the other section, that from Guildford to Surbiton, is to be constructed by the South-Western Co. The line under notice will be $7\frac{1}{2}$ miles long, and will proceed from the South-Western Station at Surbiton in an almost direct line outskirting Wimbledon Common to Putney, crossing the river to Fulham by a bridge of five arches. The cost will be £750,000, the bridge and a mile of tunnelling greatly augmenting the estimated outlay. The meeting, with but one dissentient, approved of the scheme, which is to be carried out by the independent company already formed, under the direction and at the joint cost of a committee of the South-Western and Metropolitan District Companies.

In order to enable the night-work at the new Swansea Docks to be carried out with greater regularity, the contractor, Mr. Walker, has had recourse to the electric light. Six lamps on the Brush system, worked by a 12 h.p. portable engine, have been hung near the lock excavation since Thursday, last week, and the result has been satisfactory. A staff of 500 men—one half the number at work by day—are now employed each night in the lock excavation, which is 600ft. long, 150ft. wide, and 40ft. deep, and is said to be well illuminated by the half-dozen electric lights.

On Sunday last the members of the Sunday Society paid a visit to Apsley House, by permission of the Duke of Wellington, and the same afternoon the United Arts Gallery was opened for the first time on Sundays. The members of the society visited this gallery to the number of 574, and next Sunday both the United Arts Gallery and the Herbert Exhibition Gallery are to be open to the public by free tickets, which may be had by all who make written application and send a stamped and addressed envelope to the honorary secretary, Mark H. Judge, 8, Park-place-villas, W.

THE arrangements for the International Medical and Sanitary Exhibition, to which we have referred more fully elsewhere, are now complete: the offices are removed from the Parkes Museum to the Exhibition Buildings at South Kensington. The Right Hon. Earl Spencer, Lord President of the Council, has accepted the office of president, and will preside at the opening ceremony, on Saturday, July 16th. The exhibition is to be complete on Wednesday, July 13th, and the judges will make their examinations for the awards on the two days previous to the opening.

THE late Dr. Edmund Lambert, a Bath physician, bequeathed a sum of money to the "Trustees for Improving the Dwellings and Sanitary Condition of the Poor of London." It having been decided in Chancery that the Society for Improving the Condition of the Labouring Classes was entitled to the bequest, the matter on Wednesday came before the Probate Court to decide the amount, the testator having left a blank before the word "thousand." Upon the finding of the jury, Sir J. Hannen ordered the probate of the will to be recalled in order to fix the bequest at two thousand pounds.

PROF. IRA REMSEN, of Johns Hopkins' University U.S.A., who has been engaged for some time past experimenting on carbonic oxide as a source of danger to health in apartments heated by hot-air furnaces and cast-iron stoves, has finished his investigations, and will report shortly to the National Board of Health, for whom the work was undertaken. Prof. Remsen states that he has examined the different methods in use for the purpose of detecting small quantities of carbonic oxide, and then applied the best of these methods to the study of the air of a large number of buildings. A specially-constructed cast-iron stove was used in a second series of experiments, and the air of the room in which the stove was situated was

examined under different conditions. The results, Prof. Remsen states, cannot well be given in a few words, but in general, he is of opinion that there is practically not much danger from the carbonic oxide involved in the use of hot-air furnaces and cast-iron stoves.

COMMON glue has most enormous strength and adhesive powers, if it is good. But to be good it must not have been injured in the making by decomposition, to which the material and the glue itself are peculiarly subject. If offensive, it cannot be trusted to hold wood. The strongest known glue is that made from the skins and sounds of fishes, and the strongest of this class is made in Lapland, from the skin of a perch. The Laplanders use it in making their bows, which are both strong and durable. In making it their cold climate is greatly in their favour; here a fishskin will begin to undergo decomposition before it can be dried. In making it the skins are put into a bladder, which answers for a water bath, and heated in water until a sort of glue results.

ACCORDING to the *Industrial World*, to make brick masonry impervious to water, there may be employed two washes or solutions for covering the surface, the one caustic soap and water, the other alum and water, the proportions being three-fourths of a pound of soap to a gallon of water and a pound of alum to four gallons of water, both being well dissolved. The wall must be perfectly clean and dry, and the air at least 50° F. The soap wash should be laid on boiling, with a flat brush, and so as to form no froth. After remaining 24 hours to become hard, the alum wash is applied in the same manner, but at the temperature of 60 to 70 degrees. After another 24 hours a second soap wash is put on, this being repeated until the walls are impervious.

CHIPS.

A meeting of the Architectural and Archaeological Society of St. Alban's was held in that city yesterday (Thursday) afternoon, under the presidency of the Earl of Verulam.

The music-hall in De la Beche-street, Swansea, is being reconstructed and improved, the new works including the addition of a minor hall, 50ft. by 35ft., provision of kitchens and retiring-rooms, and rearrangement of lavatory accommodation. The contract for the works has been taken by Mr. D. Morgan, of Brunswick-street, at £1,070.

At Llangennech, a village four miles from Llanelly, the foundation-stone of a new Congregational chapel was laid on Monday. The building will cost £1,500, and is erected by Messrs. Walters and John, Contractors, of Morriston.

The cemetery at Doncaster is about to be extended; the plans for the enlargement have been prepared by Messrs. Wilson and Masters, of Sheffield and Doncaster.

The annual meeting of the Sussex Archaeological Society will be held on Thursday, August 11th, and will include a visit to Ashburnham-place, near Battle, the seat of Earl Ashburnham.

The Mayor and corporation of Swansea have advertised for the name and address of "Progress" whose plans were recently submitted under motto in a competition.

The railway station at Pickle-bridge, near Halifax, is in course of entire reconstruction on a site 300 yards off, and when completed in December next, will be renamed "Wyke." The contract has been taken by Messrs. Henry Siddall and Co., of Sowerby-bridge, at about £4,000.

The Congregational chapel at Eastbourne has been reopened after the completion of extensive internal improvements. Mr. George Mitchell was the architect, and Mr. Martin the builder. The foundation-stone of a new Baptist chapel in Grove-road, Eastbourne, was laid on Saturday. Beneath the chapel, which will seat 700 people, will be the schoolroom and class-rooms, vestries, &c.

An inquiry was held at Doncaster on Tuesday week before Mr. S. J. Smith, C.E., an inspector of the Local Government Board, into an application from the corporation of Doncaster for sanction to borrow a further sum of £10,000 towards the completion of the new water-works. The town clerk stated that the works consisted of three storage reservoirs holding 290 million gallons, from whence the water is conveyed to another reservoir of a million gallons capacity at Warneford, and so into the town. The sum of £160,000 had already been borrowed; but £165,819 9s. had been actually expended; the original estimate was £80,000. The works were practically completed except about

£800 of work; but certain claims had yet to be met. Mr. B. S. Brundell had been the engineer. The inspector inquired closely into the admitted waste of water, and suggested that the district be divided into sections, and test-meters be put down. The excess money spent must be met out of current rates, and could not be borrowed.

The Steyning Union Rural Sanitary Authority is about to erect a new infirmary, in two blocks, for male and female patients, at the workhouse, Shoreham, Sussex. Tenders have been invited for the 9th inst. The works will be carried out under the superintendence of Mr. S. Johns, district surveyor, Station-road, Portslade.

Leadenhall-street and Gracechurch-street are about to undergo improvement as regards new buildings in the immediate locality of the Market, now undergoing reconstruction. A large block of shop and other property, extending in Leadenhall-street from the corner of Gracechurch-street to a distance of about 100 feet eastward, and the same length southward along Gracechurch-street to the boundary of the approach to the Market in that thoroughfare, is at present in course of demolition, preparatory to the erection of a large block of new property on the site, which covers an area of 17,000 superficial feet, and which includes the site, adjoining the market, on which the leather market formerly stood. The new premises will have handsome frontages to Leadenhall-street and Gracechurch-street, and a frontage of 113 feet to the new street leading out of Leadenhall-street to the market, which is to be formed as a part of the new scheme.—*City Press*.

Holloway's Ointment should be well rubbed upon the pit of the stomach and region of the heart in that particular form of indigestion which gives rise to palpitation, shortness of breath, and a suffocating sensation. Every distressing symptom soon yields, digestion becomes easy, the spirits light, and good health returns.—(Adv't.)

MEETINGS FOR THE ENSUING WEEK.

SATURDAY (TO-MORROW).—London Association of Foremen Engineers and Draughtsmen. Discussion upon Mr. W. Lloyd Wise's paper on "Mr. Anderson's Patent Bill." 8 p.m.

EXAMINATION UNDER THE

METROPOLITAN BUILDING ACT (18 and 19 Vict. cap. 122, Sect. XXXIII).—The Board of Examiners, appointed by the Royal Institute of British Architects to examine all persons presenting themselves for the purpose as to their competency to perform the duties of DISTRICT SURVEYOR IN LONDON, and to grant CERTIFICATES to Candidates deserving of the same, will hold an Examination on the 28th and 29th inst. Each Candidate must, on or before FRIDAY, the 22nd inst., send to the secretaries an APPLICATION, which must be accompanied by a statement drawn according to a form to be previously obtained from them; and each Candidate will be required to attend at the Royal Institute of British Architects on THURSDAY, the 28th inst., from TEN a.m. until ONE p.m., and from TWO p.m. until FIVE p.m. for the WRITTEN and GRAPHIC Examination, and on FRIDAY, the 29th inst., at TWELVE noon, for the ORAL EXAMINATION. Each Candidate on sending in his formal statement and application, must pay to the Royal Institute of British Architects a fee of TWO GUINEAS; and each Candidate, on receiving his certificate—should the same be granted to him—must pay to the Institute a further sum of THREE GUINEAS. No person will be admitted to the Examination unless he declare that he intends to offer himself as a Candidate for the Office of District Surveyor in London.

J. MACVICAR ANDERSON, Hon. Sec.
WILLIAM H. WHITE, Secretary.

TENDERS.

. Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender—it adds to the value of the information.

BRIGHTON.—For completion of works at Brighton New Club. Messrs. Linsion and Son, architects:—
Cheeseman and Co. (accepted) ... £4,278 0 0

THE BUILDING NEWS.

LONDON, FRIDAY, JULY 8, 1881.

DESIGNERS AND ARCHITECTS.

IT seems a rather remarkable circumstance in the education of the young man destined to follow the profession of architecture, that he so invariably halts on the threshold of his career, and so often feels at a loss as to his future position as to deem it necessary to ask the opinion of his friends whether he has made the right choice—as if they were better judges of the matter than himself. While the young student in the law who is reading preparatory to his examination, or the student of medicine who has duly served his time and has “walked the hospitals,” knows exactly the kind of work he will have to perform, and feels fully confident of his ability to discharge the duties of his avocation, the architectural tyro seems less fortunate in obtaining a clear idea of his duties, for he is constantly found stumbling over doubts and perplexities in his own mind, or has probably received a very mistaken notion of the work of the architect. Indeed, we know that a very large percentage of those articulated to the profession follow other avocations. It would be an easy task to prove that these difficulties and misunderstandings which beset the pupil arise from the unsatisfactory mode in which our architects are trained, the payment of premiums for terms of years, the want of a probation, and the very one-sided view of the architect's work obtained in most offices. It is not our purpose to enter into this question; we simply accept the fact, sufficiently notorious, that in a large number of cases the pupil gets a very imperfect and vague idea of the practical architect's work, and is allowed to drift for himself in a hopeless, helpless sort of a fashion into whatever class of practice he can pick up. While it has turned out many good architects, the “pupilage” system has been a rock on which many hopes have been wrecked. It is our more immediate object in the present paper to point out that the system has favoured the production of two very different types of individual, described at the head of this article. There is the young man with business proclivities and a taste for drawing, and the born artist full of enthusiastic love for his art. One turns out a business man or a practical man, the other often a mere enthusiast or an artist, whose ability is measured by his very modest assertion of his real powers. The qualification for business stands its possessor in very good stead. If he happen to be a fair draughtsman, he can invariably obtain a livelihood as an assistant, if he cannot enter into practice on his own account. In nine cases out of ten, however, he quickly gets into the latter position. In the architectural profession we may discover what has been called a good “all-round” man: one who is a good accountant or quantity-surveyor, knows a good deal about practical detail, and can write a specification, or make out a builder's account with as much facility as he can get out a set of drawings. As a matter of course, success in business awaits him. But there is another manifestation of the architectural draughtsman—the “designer” as he is sometimes ironically called. The demand for designers as assistants to architects, art manufacturers in ceramics, wood, metal, or woven fabrics, has tended to separate the designer from the architect, and the correspondence which has been going on in our pages on the relative claims of the builder-

architect and designer, or art architect as he may be more properly called, shows in what manner this class of artists has affected the architectural profession. A provincial architect who has a comfortable practice in the erection of small residences, shops, and surveys, who is not inflated with the claims of “high art” or æsthetics, and does not trouble himself about the rival claims of Gothic or Queen Anne, finds the “designer” occasionally a useful help in the preparation of perspectives, competition or show designs. The designer, not unnaturally, has the assumption to call himself the architect and his employer a “builder-architect,” and as long as such bargains are made we cannot exactly draw the line where the claim of each in the production of the design begins and ends. We consider that an architect who places himself entirely in the hands of a draughtsman as regards the preparation of his design has forfeited all right to be called its author, and must not be offended if he gets the name of a “builder-architect,” even if he does not undertake the contract himself. It is very usual, too, as one or two correspondents have shown, for the designer to become the paid servant of a contractor in a large way of business, and we know perfectly well that many of our best London firms of builders, whose names are familiar to the profession, have their own paid assistants or architectural designers who undertake to carry out the design, decoration and all, of any building intrusted to their care. Such a combination may not be looked upon with favour by the *élite* of the profession, and no doubt the practice of getting buildings contracted for by a firm who also supplies the design, is not to be commended. At the same time the practice is one sanctioned by those who admit the co-operative principle, and we should not be surprised to find it extending yet more on these lines, in spite of all the protestations of R.I.B.A.'s and others. This amalgamation of interests will not fail to extend so long as architects delegate their work to draughtsmen, for we cannot see the difference between an architect of a building getting the design prepared for him, and the contractor saving his employer the expense of a middle-man by preparing the drawings at his own establishment. One is quite as vicious in principle as the other. The designer is a specialist: he can draw with facility, though his knowledge of materials and construction is generally of the most scanty kind. He, however, manages to fill up the gap between the real architect and the business or practical architect which the pupilage system has created. In many instances he may have never seen an architect's office, as a correspondent points out, but has obtained his knowledge of architecture from Government schools. The average country practitioner has little opportunity for cultivating the artistic faculties of his pupils; the consequence being the chances are against the youthful architect ever succeeding in an artistic sphere of work; while the enthusiastic draughtsman often scorns the practical building part, and finds it equally hard to get a livelihood as an architect. Extremes meet; the one finds the other necessary. We cannot lose sight of the twofold function of the architect, his ability as an artist, and the business qualifications required. Those men who have succeeded, and have risen in the profession by their merit have generally shown a happy combination of these qualifications.

A more important consideration in this view of the subject is the competency of the designer, and his position in the profession. His antecedents may be anything but architectural, though, as we have seen, he is an admitted factor under the present régime. The great question with the profession is, Whether the designer, apart from the architect, is a desirable being, whether there can

be a true accord between the æsthetic and useful, by separating the functions of designer and architect? So long as there are æsthetes who affect to enjoy the quaint and grotesque, instead of the intelligible and natural, and people who cannot see the beauties in tertiaries and semi-tones, the artistic designer may have a useful part to perform at the present time. In justice to the architect, however, he should know something of the technical. We have always denied the possibility of securing good architecture when the plan and elevation of a building have been prepared by different men; yet there are many in the profession who do not scruple to make the plan the limit of their architectural work, and to hand over the elevations, details, and decorative accessories to the designer. We can understand an architect who has an extensive range of factories to build, or an iron roof of great span, consulting an engineer about the details, or an engineer submitting his skeleton framework or construction to an architect; but for an architect to delegate his professed details to another designer is almost tantamount to a painter obtaining commissions for pictures executed by other artists, or for a lawyer to accept a case and get a brother-lawyer to undertake it. The system has its evils: it encourages a sort of commercial agency highly injurious to the interests of art; the “designer” gets so much to do that he becomes a veritable “crib,” and a kind of illicit practice is promoted. It is dishonest towards the designer himself, for he is only encouraging a system of protection which is equally destructive to his own personal advancement as it is to commerce. People are led to believe that to get good art, high prices must be paid and only a few enriched; they are proverbially blind enough in building matters to go to a man who is either quite ignorant of what they require, but who never refuses a job, or to an eminent member of the profession, who cannot possibly find time to devote his personal attention to a work he could well afford to throw up. It is certainly vain to expect now the magnanimity recorded of many of the great artists of the Renaissance, much less to anticipate that the public will ever be discerning enough to select the most competent men in the ranks of any profession; and without competition, in spite of all its evils, is it really possible? The profession owes to itself the duty of placing the architect in his true position, and of making it clear under what limitations the draughtsman is also an architect.

NEW BUILDINGS IN LONDON.

IN Fleet-street, Ludgate-hill, Cheapside, and Cornhill, the improvements of late, both of a public and private character, have been evident. It is true these have not altered the general aspect of the City much, though they have added to its material appearance and convenience, and in a city where the price of ground, already of fabulous value, is increasing every day, it would be useless to look for any of those sweeping alterations in the lines of streets which are so common in the cities of the United States, or for the magnificent schemes of reconstruction which our French neighbours have partly realised in their own capital. Even the comparatively modest proposal to widen the precincts round St. Paul's has not been revived of late years, owing to the excessive value of property in the locality, and the same prohibitive price of land has operated in restricting many schemes of street improvement.

In the Strand the new is jostling with the old, and a few time-honoured buildings are being replaced by structures often picturesque in their composition. Dilapidated houses

afford a favourable excuse for rebuilding in a style which has lately been revived, and still promises to hold out. We may, for instance, remark the quaintly designed little front of red brick, with its gauged arches and setting of white painted frames and window-sashes, erected for the "Express Country Milk Company" in a kind of Queen Anne, the chief points of interest in which are the red-brick, white-pointed front, with its homely-looking shop-window, the framework of which has been designed in accordance with the fashion of windows of the 17th century, having a voussoir and keystone arrangement in the division. There is much to suggest the dairy in the quiet, cosy-looking fittings of the shop, the clear white enamelled tiles which relieve the spaces beneath the windows, and the pediment over the shop-front. Passing through the Strand to Fleet-street, one narrow stone façade may be noticed, not for any novelty in the design, but as indicating the manner in which a cramped frontage may be architecturalised. The flat, stilted arches of the three-light windows, with their rather coarsely-carved capitals, seem to be a little too ambitious a treatment for so restricted a front, and the pilasters at the sides, with the returned cornice are the best features. The carved swags in the pilasters are a little outré. Mr. G. Pidding is the architect. The *Daily Telegraph* new premises, higher up, have a considerable frontage. The façade is divided into three by narrow wings, pronounced by coupled Corinthian pilasters, and surmounted at the top by Mansard roofs. The centre is pierced by pedimented and arched windows, and the interfenestration is generally plain. A sense of disproportion is felt in the superposition of wide panelled pilasters over the coupled Corinthian ones below; the former crush the latter, and the large rosette in the centre and dark marble panels add to the effect. The details follow those of the advertising offices recently built on the opposite side. The façade is entirely of stone except the pilasters, which are of red granite with panels of darker materials over. The block of old houses from the Law Courts to Chancery-lane, doomed for removal, has not been touched. The site will afford a capital opportunity for business premises. There is little noticeable in Cheapside, but in Cornhill a new block of buildings, faced with stone, chiefly built for the London and Lancashire Life Co.'s new offices, with the upper stories planned as offices, may be seen on the north side. The façade has been designed with some freshness, and the architect (we believe Mr. Chatfield Clarke) has attempted at least a very suitable type of French Renaissance, the main features of the front being its division into orders, corresponding with the stories, of which there are four altogether, and the deep, carved friezes which divide them. The orders are not the Classical, but are freely designed, and the columns are coupled, except at the ends, where single columns are used. An apparent weakness arises from this circumstance, and it is a pity the ends were not more solidly treated. The principal, or ground-story, to be used for the large office, is adorned with grey granite columns in couples. The architect has secured light, and avoided a projecting porch or archway, with the commonplace pedimental head, by making the principal entrance a filling-in to one of the inter-columnar spaces. A circular pediment rests on two deep consoles, the motive apparently suggested by a wooden framework. The friezes above each of the orders are deep, and are carved in relief. Medallions, with Cupid and Eros, are the leading features, and these have been executed with Classical feeling. The first floor is relieved by double Ionic columns over those below; the windows between are of three main lights, with mullions, the faces of

which are decorated by orders in relief, and a stone transom cuts off the upper part. Another deep frieze intervenes between this and the next story, decorated in bas-relief figures with shields. There is a kind of composite order in the upper stories, and the façade is crowned by a rich corbelled cornice and four dormer gables with circular pediments and finials of rather florid detail, in which a kind of scalloped-shell enrichment largely enters. The insurance office has a plaster ceiling, decorated with ribs in the form of circles, and circular intersecting arcs, and the iron columns at the top, above the capitals, are finished as fan-shaped pendentives, with radial ribbings. The offices above, approached by a stone stairs, well lighted from an area, have no particular features. Turning down Bishopsgate-street Within, Mr. Norman Shaw's picturesque front of red brick and white-painted sashes for Messrs. Barings' Bank, will suggest new reflections to some who have not hitherto, perhaps, entertained any decided misgivings respecting the style of which he is one of the acknowledged leaders. For the curiosity of those who have not seen this latest attempt to revive brick architecture in the City, we may describe the new front—and it is merely a façade tacked on to the old buildings—as a particularly plain red brick wall pierced with windows of rather elongated proportions, having sashes with segmental heads and gauged brick arches. There is nothing very different in these to any of those seen in Mr. Shaw's other works. The front thus treated is surmounted by a massive, handsomely-moulded and modillioned cornice, as might be seen in many old buildings of the last and previous century, above which, upon a steep tile roof, peer three dormers, with richly-moulded pediments and small panes of glass, painted white. A little on one side is a wide archway built of stone, with gauged-rubbed brick voussoirs at intervals. The elliptical archway is delicately moulded on the edge, and is covered by a pediment composed of two ramps of ogee outline. These ramps are curiously broken by a small window in the centre, which pierces a portion of the tympanum. Of the merits of this composition, which has elicited much adverse criticism, we say no more than that we hardly think it will add to the reputation of the author of that earlier and better-studied building, the New Zealand Chambers, not far off. One peculiarity in the front is that the painted wood window-frames are fixed within two or three inches of the face of the brickwork, as a correspondent pointed out some time ago in these pages. In connection with street improvements, the pulling down of the houses at the corner between Gracechurch-street and Leadenhall-street, in connection with the new market, is important, as a measure calculated to relieve a very congested part of the City. A large site of considerable frontage on both sides will be thereby rendered capable of architectural amelioration. Making a long stride from the City to South Kensington, an allusion may be made to a very important building by the last-named architect, the "Albert Hall Mansions." This colossal block of red brick has the apparent effect of at once destroying the scale of the Albert Hall, which it adjoins, and unmercifully crushing Mr. Shaw's own work, Lowther Lodge, which, unfortunately, stands close to it on the east side. It is a pity, for the credit of our metropolitan architecture, such an unfortunate juxtaposition of buildings can be possible. Mr. Shaw has literally overpowered his charmingly picturesque house by the towering erection of residential flats. The composition itself has one long façade towards the park, and

is broken by three gabled projections, which stop arched balconies on each side on the first and second floors. These balconies will form very pleasant outlooks over the park. There is a general similarity in the windows, which are chiefly three-light segmental-headed, relieved by white sashes. Picturesqueness has not been lost sight of; the gables are composed of curved ramps and pediments, and the little oriels, corbelled out from the main brick cornice, with their deep-set series of members in the cornice and pediment all painted white, have a quaint effect. The stone lines of balconies and corbels, the admirably-designed and executed cut-and-rubbed cornices and string-courses, and the narrow brick pilasters from the caps of piers, break up an otherwise rather heavy composition. Relief of a more decided kind will be afforded by the two tiers of white roof-dormers in the steep roof of green slating. These high-class residences, when finished, will naturally be looked forward to by many interested to know how the seventeenth-century domestic brick style can be appropriately applied, by the best master of the style, to buildings of an ambitious residential character in flats in the fashionable quarter of London.

BALUSTERS AND BALUSTRADES.

FEW architectural features are so common as balustrades, though we occasionally find very poor or feeble apologies for them. We speak here chiefly of stone balustrades, such as are common in buildings of Classic or Italian design. Every architect knows when he sees the proportion which is most pleasing, yet it is rather curious to find that the design is left in many cases to the builder's foreman's idea, or the mason is allowed to give his own proportions and to render the architect's small scale elevation as best he can. The chances are that the beauty of a good profile is entirely lost, and that a meagre "skinny" looking object is introduced. There are at least three different types of baluster, which we may designate as the ordinary or single-bellied form, the double-bellied, and the inverted form. As the chief value of the baluster as a feature is its repetition, it is essential that a good form be selected, and the architect ought never to think it too trivial a matter to be worth giving a full-size or large-scale drawing for. The Italian architects, who were constantly using them, have left many excellent models, and the best types are those which combine graceful outline and simple treatment. The outline ought to be well-proportioned and refined. Sir Wm. Chambers, in his "Decorative Part of Civil Architecture," well describes the simple baluster, and his proportions may be accepted as almost perfect. He there says the "best proportion for balustrades of this kind is to divide the whole given height into thirteen equal parts, and to make the height of the baluster eight of those parts, the height of the base three, and that of the cornice or rail two." "Or, if it should be required to make the baluster less, the height may be divided into fourteen parts, giving eight to the baluster, four to the base, and two to the rail; one of the parts may be called a module, and, being divided into nine minutes, serve to determine the dimensions of the particular members." In the example given, the subordinate members are divided thus: The plinth and its mouldings are made equal to 3 modules; the base, including the cavetto and members, 2 modules; the plain curvilinear part of baluster, including the swelling, 4 modules; the necking and cap-members, another 2 modules; and the rail, 2 modules; thus making 13 modules in all. The proportions here given are very agreeable to the eye. Double-bellied balusters are often

used regardless of the connection in a composition. As a decorative adjunct to the base of a building, the simple form is much to be preferred for its solidity of character; but in parts of a facade, where the members are small, the double baluster, being slenderer, is a good substitute. Chambers divides the whole height of balustrade into 14 modules: 9 of these are given to double bellied baluster, 3 to the base, and 2 to the rail. The double-bellied baluster is well adapted for staircases and balconies, where a light character is necessary.

A point quite as much lost sight of by architects is the distance that should be allowed between balusters, and many lamentable failures occur through inattention to this point, or not clearly figuring the distance in the clear or from centres. Sir W. Chambers observes: "The distance between two balusters should not exceed half the diameter of the baluster measured in its thickest part, nor be less than one third of it." The pedestals which occur at intervals should not be too far apart, or the balustrade looks weak, nor should they be too close. Eight or nine whole balusters, besides the two half ones, are considered the best number between the pedestals; but of course the intervals have to be adjusted by the piers or columns below. In long ranges the balusters are broken at intervals by a die or more, flanked with half-balusters; and Chambers gives the breadth of a die at from two-thirds to three-quarters of the breadth of those of the principal pedestals. Of course the latter are regulated in width by the columns below, or the top of shaft. Those who wish to study good examples of balustrades may do well to examine those in the facades and terrace of Somerset House; and the parapet of Waterloo Bridge. The third kind of baluster is the inverted form, usually square in plan, of which we cannot say much in commendation. The double-bellied baluster is a frequent introduction in the balconies of the Venetian palaces; and is also adapted for wood or metal.

It is often a question with architects how a balustrade for a staircase may be treated. We think Chambers' opinion may be taken as a judicious one. He thinks it better to keep the mouldings of the balusters horizontal than that they should follow the inclination of the stairs, and no architect who has seen the two methods will hesitate to give preference to the former. The distances apart of the balusters ought to be rather less than for horizontal balustrades, as the thickest portions do not come opposite. Those who desire to make themselves acquainted with the subject will find the treatise of Chambers a useful guide, but our chief object is to draw attention to the very miserable designs and proportions often seen in modern-executed work, possibly owing to the fact that few draughtsmen can draw a baluster correctly.

Scarcely any architectural feature looks more meagre or weak than a balustrade in which the interspaces are made wider than the rule above given allows; the balusters become caricatures of what they ought to be, and the top rail or capping always appears crushing. Very wretched spindling-looking things often take the place of balusters, in which the swell of the balusters is reduced so much that they lose all the character essential to them. When stone balusters are used, this reduction from the standard proportions has even a more serious objection, for it leads one to suppose some other material has been employed. We frequently find balustrades in modern work of the most absurd profile, and some, even where the plinth and abacus of the baluster are made circular also, giving the effect of a lathe-turned baluster. Such faults as these are pardonable in some little builder's work, but are inexcusable in the architect's. The custom has lately become

prevalent of inverting the baluster, the bellied part being put on the top; and we find the "Queen Anneists" do not scruple to employ this and other modifications, if not distortions, of the feature for the sake of variety.

PRACTICAL NOTES ON PLUMBING.—IV.*

By P. J. DAVIES, H.M.A.S.P., &c.

UNDERHAND JOINTS.

THESE joints are shown made, and as they should be finished at Figs. 7 and 8 (see last chapter). You prepare the ends as you did for the upright joints, and as shown at section K E, Fig. 5 (also see previous chapter), and also shown at A, B, D, in the elevation, Fig. 14.

Here you see the pipe prepared, and the joint fixed in a plumber's clamp ready for soldering.

Fig. 15 shows the pipe fixed upon two bricks:

the pipe is put together as at A, B, D, Fig. 14, but weighted down to keep it steady during the time of making the joint; then place a small piece of paper under the joint to catch your surplus solder, and begin soldering as follows:—Take the felt in your right hand and with it hold the ladle three parts full of solder; to see that it is not too hot, hold the back of your hand within 2in. or so of the solder. If it quickly burns your hand it is too hot; if you can hold your hand without pain, use it; but if you cannot feel the heat it is too cold: this is soon known by a little practice. Another test is to take a little piece of newspaper and immerse it below the metal, if it blazes instantly it is too hot; if it browns quickly use it. When you begin to pour your solder upon the joint, do it very lightly, and not too much on at a time, but keep the ladle on the move backwards and forwards, pouring from E to J, Fig. 15, first on one side

of the joint to the other, and from end to end, also up the soiling, as shown at E, Fig. 15, on purpose to make the pipe nice and hot. The further in reason this heat is run or taken along the pipe the better chance you will have in making your joint; hence one reason for the long joint (as was shown at Fig. 8). Keep pouring away, and with your left hand hold the cloth C to catch the solder, and cause same to tin the bottom of the joint (especially in large joints), and to prevent the solder from dropping down.

* All rights reserved.

Now turn this solder out of your cloth up the sides of the joint and on to the top. Keep pouring the solder on and working it up round the joint until you can feel it all soft together; keep it on the work, and begin to get it as round as you can in the centre. You should in this manner get the shape as near as possible, taking care to have it all soft, and when it is in this state quickly put the ladle down and do not stop a second for anything, but with your left hand shape this side of your joint as previously shown at DEF, Fig. 8, always beginning at the outside or that part next the soiling; then take your cloth in the right hand and do this side, finishing on the top; then if you have a small joint, say up to 2in. and have been quick with your solder, it will not be set; then give the cloth a light run round all your joints, and this will make it look like a turned joint. After a little practice you will be able to wipe your joint without shifting your cloth from one hand into the other. The secret of joint-making is getting the lead to the heat of your solder, and by rough shaping the solder whilst in the semi-fluid state, or, as some plumbers do, by keeping the outside of the solder on the move round the joint until the joint is finished. Again, some plumbers make the joint very roughly first, and let it just set; after this, they take a ladleful of semi-fluid metal and pour over the joint, and as quick as possible wipe it off again. This kind of work looks exceedingly bright, and is not likely to be porous. A good joint should not have a mark with the cloth left on it, but should be as though it were turned in a lathe.

ROLLED JOINTS.

When wiping brass-work on such as unions, some plumbers cut a quantity of splints about 9in. long, and drive them into the brass-work, and then into the lead-pipe. This is called fixing for rolling (but I do not care for this practice), which is done as follows: Fix the union firm to the pipe with the splints, then place the pipe upon two pieces of, say, quartering. Take the ladle of solder, and proceed as you did with the underhanded joint. As soon as the heat is properly got up, take the cloth in the right-hand and turn the lead pipe round with the left (or get your labourer to turn it for you), at the same time hold the cloth in, or between the fingers to as near the shape of the joint as you can keep the forefinger, pressing on one side or end of the cloth, and the third finger on the other, so as to get the cloth as near the shape of the joint as possible (see Fig. 16). OO shows the point where the fingers press on the cloth; XXX shows where the thumb holds, but on to the underside.

Fig. 17 shows the general shape of the cloth.

when making underhanded fixed joints in their place; it also shows that you should bulge your cloth as at D and keep E close down on the edge of the joint. After you have done on the side or end E, work the side F, then turn the cloth into the right hand; bring up this side, and finish with a run round as a "smoother."

PNEUMATIC TUBE JOINTS.

These tubes are required to be laid very true at the joints, in order to allow the piston, or carrier, to pass on its journey uninterrupted. In order to make sure of this the company adopt the butt-joint, which is made as shown at Fig. 18. A, B is the pipe; M a steel mandril which is made to the same heat as the solder, and exactly fits the lead pipe E. This joint is made as follows: First true the ends of your pipe so that they butt together truly. Soil and shave same as in the ordinary way, then heat your mandril to the heat of the metal, or hot enough to just brown a bit of cotton-waste; remember not to have it too hot, or you will not be able to

keep any metal on the bottom part of your joint. Suppose your mandril to be just the heat, place it in the pipe, then thread the rope through the next length, and fix the end of these pipes to-

gether. Proceed to make your joint as you did underhanded joints; make it quick, and as soon as you have finished pour some water on it, either out of a sponge or otherwise. This will set your solder round the bottom, which is the touchy part of this work, because of the mandril keeping this hot. As soon as the joint is thoroughly set have the mandril drawn out.

BAD-SHAPED JOINTS.

Before I leave underhanded joints, I wish to show what my foreman of plumbers calls the "Universal joint," Fig. 19. It is just the shape

of a dutching-made plumber's joint, and Fig. 20 is the section of same. Fig. 19 is too well

known to require any description—in fact, how it is made is a puzzle. But it is not at all uncommon (when coarse solder is used) to find good-shaped joints as porous as the one shown here; hence one reason why, after making a joint, you should, when hot, rub some touch round same, which will nearly always stop up the pores, and prevent sweating. I have seen the touch (after the joint has been broken asunder) when it has penetrated its way through the solder, and the cells of the solder itself were full of the same, especially after the joint has been cut in two. Of course, it is no use to touch a joint over if it is for hot-water pipe work. Here you must always have your solder fine enough to prevent sweating.

PLUMBERS' JOINT-MAKING WITH LAMP.

For this, see BUILDING NEWS for June 10, 1881, p. 688. But for the benefit of those not sufficiently advanced in the art of plumbing, I may mention that these joints may be made quite as well horizontally as when the pipe is vertical. For testing solder, see p. 687 and 688, BUILDING NEWS, June 10, 1881.

(To be continued.)

IRON BUILDINGS.

A FEW useful hints on iron buildings are given by Mr. Matheson, in his new "Aid Book," recently reviewed by us. The author, speaking on cheapness and facility of removal, observes, in colonies and at public works, where-

ever, in fact, the requirements of a building may be of uncertain duration, minimum expenditure on them is often best. Then the chances of removal, and the ease with which a building or a shed may be taken down are important points for a contractor's consideration, and even where permanency can be reckoned on, says Mr. Matheson, the "need for cheapness may outweigh all other considerations." Where money has a high value, cheap construction is still more desirable, as the saving in interest on a low capital outlay may provide for repairs. A saving of a few hundreds of pounds may be worth to the proprietor a greater percentage, so as to enable him to renew when required.

The cheapest form of iron building or shed consists of a curved roof of corrugated sheet-iron, tied at the springing by a tie-rod, and supported by columns, such as may be frequently met with on railway sidings and wharves. Columns placed about 10ft. apart may be of the same height, and each pair of columns might carry a light T-iron principal bent to the curve with a tie-rod, and if the span is wide a king or queen posts with struts. The unit of cost in an iron building is of course the distance apart between the principals and the iron columns, and economy is best consulted when the maximum distance between the columns and principals has been reached with the security of roof covering necessary. It must not be forgotten by the designer of such erections that the greater the distance between the supports, the more efficient will have to be the girders or arches which carry the roofing, as one or more intermediate principals then become necessary, and the additional cost of these girders ought to be put against the extra number of columns required if the simpler plan be adopted of carrying each principal by every pair of columns. Of course the span of roof is the decisive point, and this has to be determined by the requirements and the space to be covered. In large buildings, such as railway stations, the lattice girder may be the most desirable and economical form of carrying the roof principals; but the further apart the columns are arranged the more necessary it becomes to make them efficient as points of loading. A very economical mode of roofing large areas like railway-stations, where the columns ought to be few, we have before pointed out in these pages. This consists in carrying the roof principals, of ordinary construction, on deep open lattice girders placed 30ft. or 40ft. apart. Each roof has, therefore, this span, the iron principals can be reduced in size and height, and the extra expense in deeper girders is more than saved by the reduction in the height and construction of the principals.

Mr. Matheson, in speaking of coverings, says that "sheets of corrugated iron are sufficiently strong in themselves to need supports only at intervals of 8ft. to 12ft.," and this limit may determine the spacing of the principals. Zinc is not so strong, and has to be laid on wooden rolls, which require supports every 6ft. or 7ft. The same author throws very little new light on roof-trusses, though it is well for the designer of buildings of this sort to remember that certain forms of trusses are more economical than others, because the divisions in length which they involve will agree with the usual lengths of rolled iron. Other things being equal, the architect must use his own judgment in determining the shape of the roof-trusses or principals; but whatever form be adopted, it must not be lost sight of that iron roofs require periodical inspection and painting more than wooden roofs. On this account the "ridge and furrow" principle has been recommended for the access it allows to every part. Thus a roof with circular or curved lattice ribs may have the ridge and furrow covering between them, the series of small roofs resting on purlins formed between the main ribs, which purlins also serve to connect and stiffen them.

Referring to roof coverings, the author very truly remarks that galvanised iron will not last long in cities or railway stations, exposed to the fumes of coal or gas. For such purposes the gauge to be selected is 18 B.W.G., and this is generally used for good work. The thinner sheets cover more surface, and are on this account sent to the colonies, especially Nos. 21 and 23, though they are dearer per ton. When once the zinc coating is rendered imperfect decay rapidly succeeds, so that economy in such matters is very dearly bought. Though zinc is more durable, it is less often used. Economy in

laying these coverings is consulted by using boarding, which enables the purlins or rafters to be placed further apart. No. 18 gauge of sheet-iron weighs about 2-8lb. per square foot, and the durability may be insured by painting. The thinner the sheets the oftener the painting is required, as even a scratch or crack on the surface causes a speedy destruction of the sheet.

Coming to the prices of buildings of this description, the author observes with reason, that it is difficult to value them according to area, as modifications are so various. The strength and weight of roofs per foot increase with the span, and the cost of the building would naturally be greater as it increased in size, height also being a factor. The price per cubic foot cannot easily be determined, as even this would vary with the span and other circumstances, and so render calculation by such a method impracticable. The only way of estimating iron structures is therefore to separate the parts or take the columns and girders separately. Mr. Matheson says: When pig-iron costs £1 per ton iron columns and other cast-iron parts fitted for a building cost from £9 to £12 per ton; but if the design be complicated, or the parts very light or ornamental, these rates may be considerably increased. Wrought-iron parts, such as girders, will cost from £15 to £18 per ton at a time when iron plates cost £10 per ton, and lighter parts, as in roof work, will cost £17 to £24 per ton." Again he says: "Omitting very small roofs, it will be found that the framing of trussed roofs, exclusive of supports and of covering, will weigh from 5 to 6 cwt. per square (horizontally measured) for spans between 40ft. and 50ft.; 6 to 8 cwt. per square for spans between 50ft. and 60ft.; 7 to 9 cwt. for 80ft.; and 8 to 12 cwt. for 100ft.," the rates being as above. A corrugated iron covering needs a very light framing, owing to its inherent strength. It weighs from 150 to 300lb. per square, according to thickness. "Exclusive of main framework, galvanised corrugated sheets cost from £2 to £4 per square; zinc, £3 to £5; tiles, £3 to £4; slates, £3 to £5; and glass, £4 to £7; these rates including the subsidiary supports." Ordinary sheds and storehouses, 12ft. high to the eaves, are priced at from £8 to £15 per square; if inclosed, from £12 to £20. Railway station roofs between 80ft. and 150ft. Mr. Matheson puts at from £14 to £25 per square, including erection and coverings. Beyond those spans, and up to 240ft., the cost of station roofs in England during the last 30 years has ranged from £25 to £50 per square. These figures have a rather wide range, as it will be seen but the circumstances are so different that it is impossible to make them more than approximate. Again, in the erection of buildings of this class, it is necessary to have properly-prepared drawings and details with every dimension and thickness given, so that the competitive prices may be based on the same footing, as any slight differences in the quality of the iron or the sectional thickness of the parts may make very considerable variations in the cost. We cannot too forcibly point out, indeed, the necessity of correct figured details in everything relating to iron structures.

MR. MUNDELLA, M.P., ON ART PROGRESS.

ON Saturday last the annual anniversary festival of the Artists' Benevolent Fund took place at the Freemasons' Tavern, under the presidency of Mr. Mundella, M.P.

The Chairman, in proposing the toast of the evening, "Prosperity to the Artists' Benevolent Fund, coupled with the Health of the President and Vice-President," said he was there, he was told, because he was officially connected with art just at present. Happening to be Vice-President of the Council, he had to propose the annual vote for supplying that institution of science and art at South Kensington with which all artists were familiar; and it might be that the reason he was there was because they were doing more to manufacture poor artists than any other institution in the kingdom. He hoped, however, that what they were doing was in the direction of giving a right tone and impulse to art, and he thought what was to be seen at South Kensington Museum justified him in the belief that it was of some value to artists—that that institution had done something for art. He, and all of his standing, could testify to the wonderfully im-

proved taste of the people of this country in all that related to art. Forty years since he was a manufacturer in a provincial town, and thirty years since he was an exhibitor in the 1851 Exhibition, from which there might have been formed a Chamber of Horrors, so far as art was concerned, that would have eclipsed Baker-street. Comparing what our textiles, furniture, and wall paper were at that time with what has superseded them now was not only matter of rejoicing to him, but made him tolerant even of those aesthetes who furnished matter for so much amusing satire in *Punch*. Aestheticism, even when it became a little effeminate and depraved, was infinitely better than the rudeness and grossness of forty years ago, and he would rather see a man worshipping a blue vase than worshipping a pint pot. Sombre colours he held to be better than the horrid mixtures that used to be common in English houses. In regard to English art, he would say that when in Paris in 1878, before the opening of the Exhibition, he was in the building and heard some French artists, who saw the inscription over the compartment to be devoted to the works of our artists—"English School"—after speaking in a depreciatory fashion of English art, began to dispute whether there was an English school at all. Speaking to Sir F. Leighton on the subject of the badinage which Englishmen had then to suffer on the subject of their art pretensions, he said, with a great deal of confidence, "Wait till our opening day, and we shall see whether there is an English school." When that opening day came he saw French artists stand aghast at the Exhibition of English Art in 1878; and, when he went to the French School, he stood aghast too, but not in admiration at what he saw, and he had no difficulty in saying that, so far as he was concerned, he preferred the modern English School to any other modern school in existence. The English School he held to be the only real school of landscape-painting in existence. Really good modern art had been revived by Hogarth, Gainsborough, and Reynolds, and from their days to the present art in England had been making wonderful progress, and had now become part of our home every-day life. It was no longer an art for the priests or for the palace—it was the art of the home and the art of the people. There was no better illustration of that than what was seen in the wonderful picture-books which reflected the social life of the present day. Grey-beards like himself, who could remember the picture-books of their youth sufficiently well to compare them with the productions of the present day, must be astonished at the contrast. No one nowadays could take up one of these children's picture-books, no matter how old he was, without receiving impressions of pleasure and delight, to say nothing of instruction and enjoyment, from them. The rising generation that was being reared on such books as those would learn to appreciate art in a manner to which those who were passing away could never attain. They were, in fact, a new revelation of art.

SMOKE-ABATEMENT.

THE Board of Trade has officially declared the exhibition of smoke-consuming apparatus, fuel, &c., to be held at South Kensington, Oct. 20th till Nov. 26th, to be "calculated to promote British industry, and prove beneficial to the industrial classes, thus conferring protection on all inventions exhibited during the time of exhibition, and for six months afterwards (in virtue of the Protection of Inventions Act, 1870)."

The Secretary of the Admiralty, Mr. Trevelyan, has also forwarded a communication, promising that the Admiralty will favourably consider application for trials of apparatus at one or other of the dockyards, in case the size and character of the appliances should in particular cases exceed the capabilities of the testing places already provided.

These communications were read at a special meeting of the committee, Mr. Ernest Hart in the chair. Present among others:—Sir Frederick Pollock, Bart., Sir A. Brady, Lady Borthwick, Miss Shaw Lefevre, Prof. Roberts, F.R.S.; Mr. Aitchison, Miss Kate Potter, and Mr. W. R. E. Coles (hon. sec.). At the same meeting it was resolved that a public meeting should be held to report progress, and to inform the public and all interested of the forward state of the existing arrangements, and a hope

was expressed that the Duke of Westminster, President of the Society, would allow the meeting to be held at Grosvenor House. It was mentioned that, in addition to premiums conferred by the committee, a series of extra prizes would be arranged, including a "Ladies' Prize" for the best smoke-consuming domestic grate, and that Mrs. Rathbone, of Kensington, had headed the latter prize with a subscription of 10 guineas.

STABLE VENTILATION.

IT has been stated by Dr. Parkes that a horse requires at least 2,166 cubic feet of fresh air per hour. The army regulations allow in new stables to each horse 1,605 cubic feet, and 100 square feet of floor-space. This allowance is shamefully deficient in many stables. The most necessary thing in planning stables is, as Capt. Galton says, to have the air moving freely through every part of them, above and around the horses when they are standing, and in all the angles between the floor and walls when the horses are lying down. How this freedom of circulation is secured it is difficult to see in the ordinary plans of these buildings. There is the door and the windows along the front; there may be, in addition, end openings and a few air-bricks: but the main spaces, occupied by the horses in the stalls, are quite closed against any free current of air, and the foul air stagnates naturally along the stalls and boxes, particularly if there be no top ventilation. As for stables with lofts and living-rooms above them, they are simple abominations, and rooms in the lofts of stables are little better than fever-dens. The most effective plan that can be adopted is to construct louver openings along the ridge, or to introduce in it a few of the ventilators on the induced air-current system. But these should be well chosen, and placed in proper positions: air-inlets, in connection with these, are necessary, above the stalls and under the mangers, so that no stagnant air can remain in these positions.

A NEW SYSTEM OF GLAZING.

THE British Patent Glazing Company have directed our attention to their patent system of glazing, suitable for railway-station roofs, docks, and mill-sheds, conservatories, greenhouses, frames, and winter-gardens, which is identical with that of Messrs. MacKenzie, Harley, and Co., to which reference is made in our "Legal Intelligence" (p. 59) this week. The patent bar which the company uses is formed from solid malleable iron of a T section, but having the cross-web shaped after a U form. The bar is enveloped in soft ductile metal, either virgin lead, copper, or other, the top only being uncovered. These bars are fixed at centres under 24in. The glass is laid on the soft metal, which acts as a cushion and prevents breakage through shocks or vibration, while the soft metal at the top half of the T section is folded down over the glass, and thus completes the glazing. The means of glazing being metallic, allowance is thus made for expansion and contraction, the glass also having clearance. Besides, as the bars are rendered anti-corrosive by Professor Barff's process, no waste of the iron is incurred by exposure to the atmosphere. Among the advantages claimed for the system are: Channels provided in the bar or astragal for conducting moisture to the outside. It can be glazed in any weather and by entirely unskilled labour. It forms a strong binding to the roof or other construction, and requires no more cross-beams or purlins than are compatible with the safety of an iron structure. It possesses a maximum of strength with a minimum of weight, and dispenses with the periodical outlay for paint and putty required by the old system.

SECTIONS OF ROLLED IRON AND STEEL.

MESSRS. MACNAUGHT, ROBERTSON, AND Co., of Bankend, Southwark, S.E., have published a useful book of sections of rolled iron and steel joists and patent compound and other girders, which will be found an acquisition to the architect's and engineer's office. The present number contains no less than 34

sheets of sections, giving in every case the lengths made and the safe loads for each span, and the weight per foot. Many of the rolled joists show compound arrangements of two joists connected together by top and bottom flange-plates or riveted vertically. In ordering any girder for a particular span, it is only necessary to quote the number of the section and sheet. Heavy rolled sections, 20in. deep by 10in. wide, are kept, as well as light sections as small as 3in. deep by 3in. wide, suitable for small verandahs or green-house roofs. These sections show also every variety of form in the flanges as well as in the proportions. The sheets of channel iron are equally complete, and contain almost any section, from small grooved bars of less than half an inch each way, to sections 12in. by 3½in. Types of rails with the weights in lbs. per yard: pile-iron, fluted door-plates, fire-bars, sash-bar sections of every conceivable form of moulded edge, numbering up to 183, cross-iron, convex-iron, T-iron, and every description of square and angle-iron are to be found illustrated. A large number of sections are quite new, and engineers, especially those engaged in iron construction, will find Messrs. Macnaught and Robertson's illustrated list of great service in being able to adapt the sectional forms found in it to their designs, thus saving considerable cost.

THE INSTITUTION OF CIVIL ENGINEERS.

THE originality, labour, and ingenuity displayed by the authors of some of the communications submitted to this Society during the past Session have led the Council to make the following awards:—

FOR PAPERS READ AT THE ORDINARY MEETINGS.

1. George Stephenson Medals, and Telford Premiums, to Thomas Forster Brown and George Frederick Adams, M.Inst.C.E., for their paper on "Deep Winning of Coal in South Wales."
2. A Watt Medal, and a Telford Premium, to John Isaac Thornycroft, M.Inst.C.E., for his paper on "Torpedo Boats and Light Yachts for High Speed Steam Navigation."
3. A Telford Medal, and a Telford Premium, to Theophilus Scrymgeour, M.Inst.C.E., for his paper on "Different Modes of Erecting Iron Bridges."
4. A Telford Medal, and a Telford Premium, to Max am Ende, Assoc.M.Inst.C.E., for his paper on "The Weight and Limiting Dimensions of Girder Bridges."
5. A George Stephenson Medal, and a Telford Premium, to Benjamin Baker, M.Inst.C.E., for his paper on "The Actual Lateral Pressure of Earthwork."
6. A Telford Premium to Richard Henry Brunton, M.Inst.C.E., for his paper on the "Production of Paraffin and Paraffin Oils."
7. A Telford Premium, to Charles Colson, Assoc.M.Inst.C.E., for his paper on "Portsmouth Dockyard Extension Works."
8. A Telford Premium, to Christian Hendrick Meyer, Assoc.M.Inst.C.E., for his paper on the "Temporary Works and Plant at the Portsmouth Dockyard Extension."
9. A Telford Premium, to Benjamin Walker, M.Inst.C.E., for his paper on "Machinery for Steel-making by the Bessemer and the Siemens Processes."
10. The Manby Premium, to Joseph Prime Maxwell, Assoc. M.Inst.C.E., for his paper on "New Zealand Government Railways."

FOR PAPERS PRINTED IN THE PROCEEDINGS WITHOUT BEING DISCUSSED.

1. A Telford Medal, and a Telford Premium, to Professor Dr. J. Weyrauch, for his paper on "The Calculation of Dimensions as Depending on the Ultimate Working Strength of Materials."
2. A Telford Premium, to James Richard Bell, M.Inst.C.E., for his paper on "The Empress Bridge over the Sutlej."
3. A Telford Premium, to John Lewis Felix Targett, M.Inst.C.E., for his paper, "Experiments on Modules for Irrigation Purposes."
4. A Telford Premium, to William Thomas Henney Carrington, Assoc.M.Inst.C.E., for his paper on "Three Systems of Wire Rope Transport."

FOR PAPERS READ AT THE SUPPLEMENTAL MEETINGS OF STUDENTS.

1. A Miller Prize, to James Bernard Hunter, Stud. Inst.C.E., for his paper on "Wood-Working Machinery as applied to the Manufacture of Railway Carriages and Wagons."
2. A Miller Prize, to Mathew Buchan Jamieson, Stud. Inst.C.E., for his paper on "The Internal Corrosion of Cast-Iron Pipes."
3. A Miller Prize, to Thomas Stewart, Stud. Inst.C.E., for his paper on "The Prevention of Waste of Water."
4. A Miller Prize, to William Henry Edinger, Stud. Inst.C.E., for his paper on "Brick and Concrete and Concrete Gas-holder Tanks."
5. A Miller Prize, to Daniel Micalister, Stud. Inst.C.E., for his paper on "Caissons for Dock Entrances."
6. A Miller Prize, to Lindsay Burnett, Stud. Inst.C.E., for his "Description of a Carriage Casting Steamship, with Detailed Investigation of its Construction."
7. A Miller Prize, to Edward Walter Nether Wood,

* Has previously received the Telford Premium, the Watt Medal, and the Stephenson Medal. † Has previously received the Telford Premium.

Stud Inst.C.E., for his paper on "The Improvement of the Old Harbour at Holyhead."

8. A Miller Prize, to Arthur Stuart Vowell, Stud Inst. C.E., for his paper on "Steel; its Chemical Constitution and Behaviour under Tensile Strain."

9. A Miller Prize, to William Mairrett, Stud Inst.C.E., for his paper on "Boilers."

HOW VENEERS ARE MADE.

THE following is the method adopted in a large manufactory in the United States:—The logs are delivered in the mill-yard in any suitable lengths as for ordinary lumber. A drag saw cuts them into such lengths as may be required by the order in hand. After cutting, the logs are placed in a large steam box, 15ft. wide, 22ft. long, and 6ft. high, built separate from the main building. This box is divided into two compartments. When one is filled entirely full the doors are closed, and the steam, supplied by the boiler in the main building, is turned on. The logs remain in this box from three to four hours, when they are ready for use. This steaming not only removes the bark, but moistens and softens the entire log. From the steam box the log goes to the veneer lathe. It is here raised, grasped at each end by the lathe centres, and firmly held in position, beginning to slowly revolve. Every turn brings it in contact with the knife, which is gauged to a required thickness. As the log revolves the inequalities of its surface of course first come in contact with the keen-edged knife, and disappear in the shape of waste veneer, which is passed to the furnace to be used as fuel. Soon, however, the unevenness of the log disappears, and the now perfect veneer comes from beneath the knife in a continuous sheet, and is received and passed on to the cutting table. This continues until the log is reduced to about a seven-inch core, which is useless for the purpose. The veneer as it comes rolling off the log presents all the diversity of colours and the beautiful grain and rich marking that have perhaps for centuries been growing to perfection in the silent depths of the great forests.

From the lathe, the veneer is passed to the cutting table, where it is cut to lengths and widths as directed. It is then conveyed to the second story, where it is placed in large dry rooms, air tight, except as the air reaches them through the proper channels. The veneer is here placed in crates, each piece separate and standing on edge. The hot air is then turned on. This comes from the sheet-iron furnace attached to the boiler in the engine room below, and is conveyed through large pipes regulated by dampers for putting on or taking off the heat. There is also a blower attached which keeps the hot air in the dry rooms in constant motion, the air as it cools passing off through an escape pipe in the roof, while the freshly heated air takes its place from below. These rooms are also provided with a network of hot-air pipes near the floor. The temperature is kept at about 165°, and so rapid is the drying process that in the short space of four hours the green log from the steam box is shaved, cut, dried, packed, and ready for shipment.

After leaving the dry rooms it is assorted, counted, and put up in packages of one hundred each, and tied with cords like bales, when it is ready for shipment. Bird's-eye maple veneer is much more valuable and requires more care than almost any other, and this is packed in cases instead of tied in bundles. The drying process is usually a slow one, and conducted in open sheds simply exposed to the air. The mill will cut about 30,000ft. of veneer in a day, and this cut can be increased to 100,000 if necessary. The timber used is principally curled and bird's-eye maple, beech, birch, cherry, ash, and oak. These all grow in abundance in the vicinity.

A new parish church is about to be erected at Mather by H. M. Office of Works, the site being that recently occupied by the "Lord Raglan," in the High-street. The contract has been taken by Mr. John Jones, of Llanymyrdan, and building operations were commenced last week.

The parish church of Impington, Cambs., has been formally reopened after restoration, including the laying of new floors in nave and chancel, replacement of high pews by oak benches, erection on stone base of a new oak pulpit formerly in Histon Church, and erection of new altar and vestry. Mr. Ewan Christian, of Whitehall, was the architect.

At the Trinity Quarter Sessions for Berkshire, held last week, a report by Mr. Joseph Morris, of Reading, the county surveyor, was adopted, recommending the partial rebuilding of Briscot-bridge near Pangloss, at an estimated cost of £50,000, to be carried out by a local mason by day charge.

The foundation-stone of a mission-chapel in St. John's parish, Billingsgate, was laid on Tuesday week. Mr. Dixon is the architect, and Messrs. C. Lloyd and Sons are the contractors; the cost will be £1,300.

Building Intelligence.

BOLTON.—Last week the new church of All Souls, situate in Astley-street, off Blackburn-road, Bolton, was consecrated. The new church, which has been erected from the designs of Messrs. Paley and Austin, of Lancaster, is of the Late Decorated period of Gothic architecture. The plan consists of a nave, which is a parallelogram, 86ft. long and 52ft. clear span, without aisles or arcades, but with a tower at the west end 26ft. square; and at the east end a chancel 46ft. long and 25ft. wide, with polygonal end, and north and south aisles, the eastern part of the north aisle being utilised for the organ, and that of the south aisle as a choir-vestry, with additional clergy-vestry on the east. The chancel and its aisles open into the nave with three lofty arches, the chancel arch being 36ft. to the apex. The main object in the plan has been to secure an unobstructed space as far as possible, the whole church, with the exception of the western tower, forming a complete parallelogram. The total expenditure upon the structure and its accessories has been about £20,000. Adjoining the church are schools, which were erected in 1877, from the designs of Mr. J. J. Bradshaw, of Bolton. They have cost about £7,000.

BRISTOL CATHEDRAL.—Dean Elliot, as treasurer of the Bristol Cathedral Completion Fund, published on Friday his half-yearly report, in which he expresses gratification at the response made to his appeal in January, for funds to enable the south-west tower of the new nave to be raised to the same level as that at the north-west angle of the same front. Towards the cost, £650, £588 13s. 4d. has been received, and the work has therefore been commenced by the contractors, Messrs. Booth. It will, he remarks, give due effect to the beautiful western porch, the carving of which has just been finished. Mr. Dodd has promised a further £500 to be paid "when a reasonable prospect of finishing both towers presents itself." The chapter-house at the western end of the cathedral has been taken down, and in the autumn the Chapter will consult their architect, Mr. G. E. Street, R.A., P.R.I.B.A., as to the course to be taken in respect of the two houses to the west of the cathedral.

BURHAM.—The memorial-stone of the new church at Burham was laid on Wednesday week. The church is to accommodate 380 persons. The plan consists of nave, aisles, chancel, transepts, vestries, a narthex porch entrance, and a central tower; the whole designed in the 14th-century Gothic. The tower, being at the cross of the church, will form a landmark in the midst of the parish. The roofs of the nave, aisles, and transepts will be open-timbered, and the ceilings of the chancel and tower will be groined in pitch-pine. The church will be lighted by candelabra and candles with oil-burners. Mr. E. W. Stephens, of Maidstone, is the architect, and the proposed cost is £1,500.

CASTLEFORD, YORKS.—Further considerable additions are being made to Red Hill House, the residence of Mr. J. Austin, J.P. The style of the building is Elizabethan, stone-dressings to all windows and the main entrance, also a stone terrace to the front, lead glazing to the top part of the windows. The contractor is Mr. Thomas Hinsley, of Carlton, near Selby. New workmen's cottages with stabling are to be built, the style of which will be Elizabethan with stone dressings. The gables have ornamental barge-boarding and plaster eave to eaves. The architects are Messrs. William Lewis and Son, 46½, Stonegate, York.

FOXTON, CAMBS.—The parish church of St. Lawrence, Foxton, was reopened by the Bishop of Ely, after restoration, on Tuesday week. The church consists of chancel of the 13th century, nave and aisles of Decorated Gothic character, chantry-chapel inclosed by a screen, and west tower. The chancel was restored a few years since from Mr. Ewan Christian's plans, and the restoration of nave, aisles and tower has now been carried out by the same architect, under the supervision of his chief assistant, Mr. Parbury. There was, till now, no chancel arch, but one has been erected in half-timbered work of oak. The floor, which was brick-faced, is now laid with Minton's tiles; the old oak seats have

been patched and some new ones of pitch-pine added. A new window has been opened at the west end of south aisle. The roofs have been almost renewed, except the principal timbers. The work of restoration was commenced by Mr. E. Brown, of King's Lynn, and has been carried out by Mr. Bardell, of the same town; the cost has been about £2,500.

LEWISHAM.—The new Sunday-school buildings in the Court Hill-road are now completed, and have been fitted up and decorated for a fancy bazaar in the old English style, by which a large portion of the cost it is hoped will be raised. The new structure, including infants' room and a large number of class-rooms, will accommodate upwards of 500 children. Heating and ventilation have been especially attended to, and the whole of the work carried out in Kentish rag and Bath stone and other substantial materials by Messrs. Staines and Son, builders, of Great Eastern-street, London; the architect being Mr. George Sherrin, of No. 2, Broad-street Buildings. The total cost is about £4,000.

LICHFIELD CATHEDRAL.—An appeal has just been issued by the Dean and Chapter of Lichfield for further contributions in aid of the restoration of the west front of the cathedral. On this work the sum of £22,692 9s. 4d. has been expended during the last few years, with which considerably more than two-thirds of the undertaking has been completed. The twin western spires are now thoroughly restored, and finished with lightning conductors on approved principles. The whole of the south-west tower and the upper stage of the north-west tower, as well as the intervening gable, with the great western porch beneath it, are now completed; leaving yet unrestored the greater part of the north-west tower. For the remaining work, which will probably cost a further sum of £10,000, the Dean and Chapter will have to depend on voluntary contributions, and if these are supplied there is no reason why the whole work should not be accomplished in two more years. The present contract will terminate in a few months, and the writers of the report remark that "it would be lamentable indeed if at this advanced stage of the operations the Dean and Chapter should be obliged to part with their contractor, Mr. Thompson, and his excellent staff of operatives, and to see the scaffolding removed, thus involving a great and serious loss upon the undertaking."

NEW SWINDON.—The new district church of St. Paul, New Swindon, was consecrated on Tuesday week. It consists of a nave, 8ft. by 24ft., and lean-to aisles 12ft. wide. The walls are of local brick, with bands of grey Staffordshire brick, and the arcades are carved on Forest of Dean piers with caps and bases of Stoke-ground Bath stone. The nave-roof has a panelled polygonal ceiling, with beams and moulded king-posts exposed. All the woodwork is left unstained and unvarnished, and the internal walls are of pointed brickwork. The aisle windows are of three lights, and above are clerestory circular-cusped windows. The cost has been £1,000, and it is proposed hereafter to add chancel, organ-chamber, vestry, and tower. Mr. Edmund B. Ferrey, of Spring-gardens, London, is the architect, and Mr. William Jones, of Gloucester, the contractor.

NORTH CURRY.—The parish church at North Curry is being restored under the direction of Mr. John Oldrid Scott, as regards its nave, aisle, and transepts; and the chancel part, from the designs of Mr. Ewan Christian, of Whitehall Place, S.W., the architect to the Ecclesiastical Commissioners. North Curry church is a particularly interesting one, and has a central octagonal tower. The church stands in the midst of a graveyard, in which are the remains of a good ancient cross. One point of exceptional interest about the building is the excellent groining under the tower. The work is now being rapidly pushed, and it is hoped that in a few months the renovated building will be ready for re-use. Mr. Charles Trask, of Norton-sub-Hamdon, is the contractor; the carved stone-work is by Mr. Harry Hems, of Exeter; and Mr. G. Hannaford is the clerk of the works.

NORWICH.—The first portion of the new buildings of the Norfolk and Norwich hospital, viz., a pavilion and central administrative block, was formally opened on Thursday, the 30th ult. The buildings are in the Queen Anne, and will consist of four blocks, besides

the chapel and out-patient department. The administration block has two pavilions on either side, and consists of a basement and three stories above. In the basement are kitchen 51ft. square, housekeeper's room, servants' hall, scullery, stores, &c., with a wide corridor containing lifts. On the ground-floor is entrance corridor, 12ft. wide, leading to waiting-hall 50ft. square; to the right are porter's room, library, surgery, dressers' room, and dispensary, and to the left secretary's room, board-room, matron's and store room. Above are the resident officer's sitting and bedrooms. At the rear of this block is a one-story building consisting of operating theatre 40ft. by 20ft. surrounded by six small wards for one and two patients each, a scullery, nurses' bedroom, bath, and lavatory. There has also been completed a pavilion, approached from the administration block by a 10ft. corridor, and consisting of two stories, each divided into two wards 100ft. by 26ft., two small wards, nurses' room, and scullery; at each end of the block are turrets, containing bath-rooms and lavatories. The heating is by open fires in the wards and principal rooms, supplemented by hot-water coils and pipes, and all the corridors are heated by hot-water coils. A hot and cold water service is laid over the whole hospital, two sets of boilers, capable of use together or separately, being fixed in a central situation. The wards and over-kitchens are built on a fireproof principle, with iron girders bedded in concrete. Messrs. T. H. Wyatt, of London, and Edward Boardman, of Norwich, were appointed joint architects; but since Mr. Wyatt's death the appointment has been solely in Mr. Boardman's hands. Messrs. J. W. Lacey and Co. were the contractors, and Messrs. G. W. Haden and Son, Trowbridge, fixed the hot-water supply and heating apparatus. We illustrated the new hospital in the *BUILDING NEWS* for June 13, 1879.

NOTTINGHAM.—The new University College at Nottingham was opened last week. The buildings occupy an excellent position in a central part of the town, and the site is inclosed by wide, open streets, namely, South Sherwood-street, Bilbie-street, and Shakespeare-street. The principal front is towards Shakespeare-street, and is 260ft. in length and 60ft. in height. The style of the building is Gothic. The general outline of the front is composed of the principal entrance-gable in the centre, projecting considerably from the general line, and terminated at each end by gables, also projecting. These three gables have massive pinnacles at their angles, rising from the ground-line. The façade between the centre and the two end gables is divided into two-light windows, with shafts in the jambs, and with shafted mullions. The upper floor is formed into a continuous arcade of single-light windows, with piers between, formed of double-coupled columns. These ranges of windows, on the ground and first floors, are broken in the centre by projecting bay windows of different treatment, with square heads at the top filled in with tracery. These bay windows are carried the whole height of the building, and their lofty roofs are carried into the main roof. Between the bays and the wing are placed four dormer windows. The central entrance-gable is the principal feature in the front, and is divided on the ground-plan into three pointed open archways, with clustered columns and beautifully carved capitals. On the first-floor level, over the three archways, are three windows which light the main entrance-hall and are filled with Geometrical tracery, with shafts to the jambs and mullions. The upper part of the central gable is covered with diaper-work, and divided by a broad band of sculpture, representing a school of students of the arts and sciences, and also by three large medallions, in high relief, of Music, Sculpture, and Painting. In each of the three gables of the principal front are placed two statues, 7ft. 6in. high, on pedestals, with canopies over, of Shakespeare, Milton, Bacon, Newton, Watt, and Cuvier. These statues, which are executed in the same stone as the building, add greatly to the character of the front, and are the work of Farmer and Brindley, of Westminster. In the centre, at the junction of the principal gable and the side roofs, is placed a fleche, or spire, of wood covered with lead, rising to a height of 120ft. The façades towards Bilbie-street and South Sherwood-street are treated in a similar manner to the principal front, and designed to group

with it, and to form a picturesque outline. The building throughout is built of Ancaster stone, of a bright, warm colour. The interior of the building is simple in its arrangement, but very convenient. The entire cost of the whole works, including furniture, fittings, and decoration, is about £70,000. The workmanship throughout has been carried out under the supervision of Mr. Richard Bates, the clerk of works, from the plans of Messrs. W. and R. Mawson, architects, Bradford.

CHIPS.

A new place of worship, in connection with the United Methodist Free Churches, was opened on Thursday week, in Cloughton-road, Birkenhead. The architect was Mr. R. H. Roberts, of Everton; the contractor for the work was Mr. Edward Legge, of Birkenhead. The building is constructed of brick, with red brick facings. Seat accommodation has been provided for 550 persons.

The memorial-stones of a new Oddfellows' lodge at St. Agnes, Cornwall, were laid on Friday week. Br. Richard King, P.G., was intrusted with the preparation of the plans. The building will be 60ft. by 33ft., and is to be built with Bodys' stone, with Carmarsh granite dressings. The hall will seat 300 people.

The foundation-stone of a new Sunday-school for Holy Trinity parish, Swansea, was laid on Thursday, the 30th ult. The building will be Gothic in style, and will be erected from Yeo-street; the dimensions are 50ft. by 30ft. Mr. David Morgan, of Brunswick-street, Swansea, is the contractor, and the cost will be about £720.

Brompton Ralph parish-church, Somersetshire, was reopened last week after restoration, the works including entire rebuilding of chancel, raising of nave walls and new roof to same, and erecting a new chancel-arch in Ham-hill stone.

A series of memorial stained-glass windows have just been placed in the Roman Catholic Church of the Sacred Heart, Camberwell, by Messrs. Livers, Barraud, Westlake, and Co.

At the last meeting of the School Board for Great and Little Brompton, Cumberland, plans for new schools, prepared by Mr. Banks, their architect, were approved and ordered to be executed at once.

The temporary iron church of St. Paul's, Bedford Park, Batham, was opened on Saturday. It has been built by Mr. J. C. Hawes, of Wandsworth Common, consists of nave 61ft. by 36ft., and chancel 17ft. by 20ft. across, and cost £500.

Parish-schools are about to be built in connection with St. John the Divine's Church, Halifax, from the plans of Mr. Richard Horsfall, of Post-office Buildings, in that town.

It has been decided that the Worcestershire memorial to the late Archdeacon Hone shall take the form of completing the restoration of Hidesowen church. The nave and chancel were restored at a cost of £6,000 a few years since from the plans of the late Sir Gilbert Scott, and it is proposed to complete the work by repairing the tower, spire, and aisles. A striking feature of the church, said by Sir G. Scott to be without parallel in England, is the insertion of the tower in the nave, nearly midway between east and west.

A visit of inspection was made by the chairman and directors of the Swindon, Marlborough, and Andover Railway, of the first completed section, that from Swindon Junction to Marlborough. Mr. J. C. Shopland is the engineer.

At a recent meeting of the committee formed for the purpose of presenting a pastoral staff to the Bishop of Bath and Wells, a design by Mr. J. D. Sedding, of London, the diocesan architect, was provisionally accepted.

An inquiry was held at Keighley on Tuesday week before Mr. C. N. Dalton, one of the inspectors to the Local Government Board, with respect to an application from the Keighley local board to borrow £41,500. The town clerk explained that of this sum £28,000 was required for waterworks purposes, including £15,000 for the Sladen scheme; £2,500 was asked for private streets improvements, £6,000 for public streets improvements, and £2,700 for completion of purchase of sewage farm. No opposition was raised to the proposal.

An accident occurred at the Cardiff Gasworks, Grangetown, which will delay the completion of the extension by several weeks. Messrs. Horton have taken the contract for the erection of a large gas-tank and gasometer at the works, and on Friday, while a ring of riveted iron plates for the gasometer were being lowered into the stone well, under the supervision of the foreman, Mr. Gilbert, one of the timber supports snapped, all the others following in quick succession, causing a complete collapse. Fortunately, no workmen were in the tank at the time.

COMPETITIONS.

BIRMINGHAM.—At the meeting of the Birmingham Town Council on Tuesday, in accordance with the recommendation of the Markets and Fairs Committee, made at the last meeting of the council, Mr. M. J. Hart proposed that the plans now submitted by the Markets and Fairs Committee, bearing the motto "En Avant," for the erection of shops and other buildings in St. Martin's-lane and Jamaica-row, in connection with the covering in of the Smithfield Vegetable Market and other works authorised by the Council, be approved, and that the Committee be empowered to carry out the work at a cost not exceeding £11,000. In accordance with the resolution of the Council requiring that competitive plans should be obtained for all works involving an outlay of £10,000, the committee invited three firms of architects in Birmingham to compete for the preparation of plans for the market buildings fronting St. Martin's-lane, and to include the re-erection of the Woolpack Hotel, and the gentlemen to whom application was made readily consented to engage in the competition. Three plans had been sent in, and after a careful examination of them, the committee had selected the one signed "En Avant." The elevation was considered to be the best of the three, and the various rooms and accommodation provided would, in the opinion of the committee, meet most adequately the wants of the public. Mr. Brinsley seconded the resolution, and it was passed. Alderman Kenrick said he could not congratulate the committee on the elevation presented to the Council for acceptance; but as the committee had had greater opportunity of examining the three plans, he was quite content, on that occasion, to be guided by their judgment. He doubted whether £14,000 would cover the erection of such a large block of buildings as was shown on the plan, and if the committee obtained tenders for that amount, he should congratulate them very much. Mr. M. J. Hart reminded the Council that the £11,000 asked for that day was not the cost of erecting the buildings shown on the plan signed "En Avant," but the additional cost. Still, they hoped to get the whole of the work completed within the sum asked for altogether, viz., £35,000. The Mayor stated that Messrs. Osborne and Reading, architects, of Bennett's Hill, Birmingham, were the authors of the accepted design.

LIVERPOOL.—In the pending competition of designs from architects for the New Exchange Station, Liverpool, in connection with the Lancashire and Yorkshire Railway, nothing has yet been decided finally, though Sir Jno. Hawkley, the official referee, is said to have made his inspection of the plans this week. Forty-four sets of designs have been received. After the award has been arrived at, the public will be admitted to see the drawings, which are arranged on trestles in a large hall at Manchester. There were over 300 sets of conditions of competition issued.

WESTMINSTER.—A limited competition is about to be held for the completion of the National Opera House on the Thames Embankment, in the form of a club house, and of course utilising the present walls and foundations. Among the competitors are Messrs. Fowler and Hill, the architects engaged on the original buildings, and the competition plans are now being prepared.

The Cumberland Industrial School for Boys is about to be informally opened. It has been built at a cost of about £9,000, from the designs of Mr. John A. Cory, the county surveyor, and it was reported to the recent quarter-sessions that the building will be completed within the specified time, and within the estimated cost.

During the progress of restoration at the parish-church, Farnham, Surrey, a 12th-century three-light window was found in the east wall of north transept, and it will be opened out. Mr. Woodyer, of Guildford, is the architect, and Messrs. Goddard are the contractors. A window in the south transept has just been filled with stained glass by Messrs. Powell, of Whitefriars, London.

A large block of licensed premises, at the corner of King and Regent streets, Great Yarmouth, were reopened on Saturday, after rebuilding and setting back. The frontages are of red brick, with Portland-stone dressings. Messrs. Bottle and Olley, of Yarmouth, were the architects, and Mr. J. Leggett, of the same town, was the contractor.

ST. CUTHBERT'S NEW CHURCH, USHAW.—COOMBE WARREN.
WIMBLEDON.—DESIGN FOR A GAMEKEEPER'S COTTAGE.—
HOLY TRINITY CHURCH, BURTON-ON-TRENT.—BOWLING
GREEN, BRADFORD.

OUR LITHOGRAPHIC ILLUSTRATIONS.

ST. CUTHBERT'S NEW CHURCH, USHAW.

Our double-page illustration to-day shows the new R.C. collegiate church of St. Cuthbert, at Ushaw, from the interior perspective drawing now at the Royal Academy Exhibition. Messrs. Dunn and Hansom, architects, of Newcastle-on-Tyne, are the authors of the work. We have no further particulars.

COOMBE WARREN.

This house, of which we give a view to-day of the entrance-front, is the property of Mr. B. W. Currie, and is picturesquely situated near the road from Wimbledon to Kingston, backed by Coombe wood. The part illustrated was commenced in 1870 to replace portion destroyed by fire the same year, the original structure in the half-timbered style having been built in 1831. Externally, the building is of red brick, with dressings of Tisbury stone, medallions of red terra-cotta, and a red tiled roof. The builders of the principal portion were Messrs. Myers.

"BUILDING NEWS" DESIGNING CLUB—A GAME-KEEPER'S COTTAGE.

To-day we give drawings of the two chosen designs, which we placed on an equal footing. "Quiet and Simple" was, on the whole, the better plan, though we do not quite like the corner-sort of entrance to the sitting-room, and a fireplace between two doorways is not the most convenient arrangement. "Jack's" design is less economical, but has much to recommend it.

HOLY TRINITY CHURCH, BURTON-ON-TRENT.

We illustrated the interior of this church in our issue of June 4, 1881, when a brief description of the building was also given. The architect is Mr. John Oldrid Scott.

BOWLING GREEN, BRADFORD.

The accompanying illustrations delineate the layout of the above park, also the entrance-bridge and gates. The designers are Mr. Lister K. Isham, landscape-gardener, Brighouse, and Mr. George Hewarth, an architect and surveyor, Bradford, who, some two years ago, in an open competition, out of a list of 22 competitors, succeeded in carrying off the first premium of 10 guineas, awarded by the Bradford Corporation for the best design for laying out the park and proposed buildings to be erected thereon. The park covers an area of nearly 50 acres, and is the fourth park possessed by the inhabitants of Bradford. It was opened to the public on the 14th of September last by the Mayor of Bradford, Mr. Angus Holden.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

ST. ALBAN'S ARCHITECTURAL AND ARCHÆOLOGICAL SOCIETY.—A meeting of this society was held in the Council Chamber, St. Alban's, on Thursday week. The Earl of Verulam, who presided, said: "Ladies and gentlemen, how much we may quarrel amongst ourselves whether there is to be a high roof or a new roof, or whether there is to be a Perpendicular window at one end of the Abbey or not, yet I am sure we shall all join together in unanimously thinking that it is the very best thing we can possibly do to preserve the ancient monuments in every neighbourhood and preserve a record of them; and we ought to be much obliged to those gentlemen who take pains so to do, and hand down in papers read upon occasions like the present, the state of things which now exist, in order that we may follow the example—the good example—of our ancestors, and do what we can to make old England as comfortable as possible to those people who live in it." Canon Davys then read the record of business of the last meeting. These having been confirmed, Dr. Griffith read his paper on "The Recently-discovered St. Alban's Parish Registers," after which the Rev. Canon Davys read his paper, which was entitled "A Brief Review of the Restoration Works since 1877 in St. Alban's Cathedral."

CHIPS.

At the Essex midsummer quarter-sessions, held last week, the Wickham Bishops proposed site for a second lunatic-asylum was definitely abandoned, on the ground that, after the expenditure of £7,281 under Messrs. Easton and Anderson, engineers, in boring for water, none had been obtained. A letter was received from Mr. Stock, the county surveyor, asking for some remuneration for the time and labour expended in the preparation of working drawings for the Wickham asylum. Mr. Stock said that he was personally engaged on the business for 153 days of eight hours each, and that seven clerks were, amongst them, engaged for 442 days of eight hours on the work, which work, putting his own time at five guineas per day, and the clerks at actual value, amounted to £1,050. Besides this, there were travelling-expenses and stationery, the whole value, on the ordinary professional rate, being not less than £1,400. All this labour and material were thrown away, as he now had to prepare fresh plans for additional buildings for 450 patients at Brentwood. The court of quarter-session voted Mr. Stock £300 as a special gratuity: the plans to be the property of the county.

At a meeting of the school board for Merthyr, held on Friday, Mr. John Williams, architect, of that town, was intrusted to prepare plans for additions to the schools at Grangetown.

Stockton Church, near Salisbury, was reopened on St. John the Baptist's Day, after restoration effected at a cost of £1875, the works including rebuilding and enlargement of the north aisle, erection of new oak roof, removal of gallery, and reseating of nave.

The new Chichester and Milhurst Railway, constructed by the London, Brighton, and South Coast Railway Company, was officially inspected by Colonel Yolland, Chief Inspector of Railways to the Board of Trade, and the line will be opened for traffic on Monday next.

At Dublin University, on Thursday week, the degree of Doctor, "in Utroque jure," was conferred on Mr. Bindon Blood Stoney, C.E., City Engineer of Dublin.

A new post-office is being built in St. Thomas-street, Weymouth, and will soon be opened. The style is Elizabethan, the lower part of frontage being of Portland stone, and the upper stories of red brick with stone dressings. The building has a frontage of 35ft., and a depth of 100ft. The plans were furnished by the Department; Mr. L. Bartlett is the contractor, and Mr. Jerrard, the foreman, the stone carving being executed by Mr. Peters, of Broadway.

Memorial-stones of new Wesleyan schools in Saltaire, Tewkesbury, were laid on Tuesday week: Messrs. T. Collins and Sons, of Tewkesbury, are the builders.

An inquiry was held at Torpoint, on Tuesday week, before Mr. Arnold Taylor, C.E., Local Government Board Inspector, with reference to an application from the rural sanitary authority of St. Germans, for sanction to borrow £6,000 for providing a water supply for the parish of Torpoint. The scheme was explained by the engineer, Mr. R. Wavish.

PARLIAMENTARY NOTES.

PREVENTION OF FLOODS.—The Rivers Conservancy and Prevention of Floods Bill, as amended by the Select Committee, was issued on Tuesday. The Bill contains two important changes affecting city and borough populations contained in the following new clause:—"The Council of a municipal city or borough having, according to the census for the time being in force, a population of not less than 25,000 inhabitants, may, on their application, be constituted, by the provisional order made by the Local Government Board, after such local inquiry as is required by this Act, a Conservancy Board for a district corresponding with the area of their municipal jurisdiction. The Local Government Board may also, on the application of any such Council, declare by provisional order that any expenses incurred by them as such Conservancy Board shall be defrayed either wholly or partially out of the city fund or city rate, or borough fund or borough rate, instead of in the manner in this Act provided for defraying the expenses of conservancy boards, and may also on the like application make the like provision in any case where the area of any such city or borough as aforesaid is constituted a sub-district of a conservancy district under this Act, and is placed under the charge of the Council as the committee for such sub-district." The new sub-clause introduced declares that no Conservancy Board, save so far as expressly authorised by provisional order confirmed by Parliament, shall be entitled "to interfere with in such manner as injuriously to affect the right to any waters, watercourses, springs, streams, or gathering grounds belonging or appropriated to or used by any municipal corporation or other local authority, or any incorporated company for the construction of waterworks and the supply and distribution of water, or the reservoirs or other works for the supply and distribution of water of such corporation, authority, or company, or to interfere with in such manner as injuriously to affect any works for the utilisation, treatment, or disposal of sewage, constructed under the express authority of any Act of Parliament."

ILLUMINATING LIGHTHOUSES BY GAS.—In reply to Mr. Gray, Mr. Chamberlain stated on Tuesday that the system of illuminating lighthouses by gas, patented by Mr. Wigham, of Dublin, had been strongly recommended by Sir William Thomson, F.R.S., and Professor Tyndall, Scientific Adviser to the Board of Trade, the Trinity House, and the Board of Irish Lights, but not to the exclusion of other systems. The Trinity House, in January, 1875, recommended the further development of the system in Ireland. The question of the hon. member suggested some official opposition to the system on the part of two distinguished officers of the Board, the Messrs. Douglas. It was their duty from time to time to offer their opinion on the systems of lighting, but on no occasion had they exceeded their duty in this respect.

CENSUS (ENGLAND AND WALES) PRELIMINARY REPORT.—Lord Carrington, in laying this report on the table of the House of Lords, said, on Tuesday: The Census Act requires that the preliminary abstract of the census taken on the 4th of April last should be laid before Parliament within three months after the 1st of June. It is satisfactory that the Registrar-General has been able to complete this abstract at so early a date. This is not the time to go into particulars, but it may be interesting to know that the total population of England and Wales is now 25,968,286, being an increase since 1871 of 3,256,020. The rate of increase was higher than in any decennium since 1831-41. The birth-rate was unusually high, while the death-rate was still more unusually low. The higher birth-rate in 1871-81, as compared with 1861-71, implies the addition of 26,774 persons beyond the number according to the previous rate, while the lower death-rate implies that 299,385 persons survived who according to the previous rate would have died—a result which seems to show that modern sanitary legislation has produced useful and important effects. It may be added that the population of the metropolis is now 3,814,751, showing an increase of 569,311, while the population of the City of London has decreased by 24,414.

The village of Fochriw is being supplied with water by the rural sanitary authority of Merthyr. The contract has been taken by Mr. Gould, and is being carried out under the supervision of Mr. J. Jones, the surveyor to the sanitary authority.

It has been reported to the Margate town council that the Marine Drive, designed and constructed by Mr. Albert Latham, C.E., has cost the borough £39,550, or £19 per foot linear. The estimated expenditure was £40,000.

St. Michael's Church, Newquay, Cornwall, was reopened on Wednesday week, after enlargement, by the addition of a south aisle, accommodating 200 persons. The work has been carried out by Mr. Libby, of Newquay.

'To a practical man, with a taste for mechanics, and bumps of constructiveness fairly well developed, we can give no higher mental treat than a couple of hours spent over the numbers of that truly marvellous publication the *Eng. Mechanic*. In a hundred and fifty odd pages that make up bulky mass of letter-press, there is recondite information on just every conceivable subject, ranging from how to construct a mouse-trap, to the latest method of calculating the phases of an orbit.—*The Brightonian*. Price Two pence of all newsmen, or 1 free 2½d.—31, Tavistock-street, Covent garden, W.C.

TO CORRESPONDENTS.

We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.
 Remittances and Post-office Orders to be made payable to FASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement is inserted for less than half-a-crown. Special terms for insertion of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 6s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is ONE SHILLING for TWENTY WORDS, and Sixpence for every eight words after. All Situation advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in serial advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound annum (post free) to any part of the United Kingdom; the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33s. 30c.). To India (via India), £1 10s. 10d. To any of the Australian Colonies, New Zealand, to the Cape, the West Indies, Canada, or Scotland, or Natal, £1 6s. 6d.

Mr. CHARLES WILSON, of 13 and 15, Laithe-street, New York City, is authorised to receive American subscriptions at the rate of 6 dols. 40c. per annum.

Mr. R. M. TUTTLE, of Titusville, Penn., U.S.A., is also authorised to receive subscriptions at the same rate. Charges for binding the half-yearly volumes, 2s. each.

NOTICE.

Vol. XII. commenced last week. In the present issue are published the title and index to Vol. XL., and bound volumes and cases will soon be ready.

N.B.—Bound volumes of Vol. XL. should be ordered at once (price Twelve Shillings), as only a limited number are done up. A few bound volumes of Vol. XXXIX. may still be had, price Twelve Shillings; all the other volumes are out of print. Most of the back numbers of former volumes are, however, to be had. Subscribers requiring any back numbers to complete Vol. XL. just ended should order at once, as many of them are run out of print.

Correspondence.

NITARY PLUMBING AND PLUMBERS' WORK.

To the Editor of the BUILDING NEWS.

SIR,—To revert to Mr. Hellyer's third lecture, will be remembered that Mr. Hellyer asserted, building a house for himself, he would have in his traps for the w.c.

In his lecture of the 30th ultimo and 1st inst., he, however, adopts quite another theory, inasmuch as he said, "That where the trap was smaller than a waste-pipe, no good flushes could be sent rough such piping to cleanse it"; he also says at the inlet to the trap should be larger than the body of the trap (quite so), but I maintain that in general practice this cannot be done, and such theory will stand, for the following reasons:—Take an ordinary lin. lavatory basin, washer and plug (which is considered to be a large size), and have the strainer bars across it, what size trap would he require? Certainly not more than a ½ in.

Now, fancy any sensible plumber fixing a ½ in. trap and waste-pipe from a lavatory. It would be simply ridiculous. My idea is that they should never be less than from 1 in. to 1½ in. throughout, including washer and plug.

Next let us take that part of the lecture in your last week's issue, on page 9, line 20, 3rd column, where it speaks of Mr. Hellyer being frequently interrupted by suggestions for making the experiments more complete and fair. I may say that, although Mr. Hellyer stated he was not aware of the working model of the O-trap exhibited by him being extremely unfair, it nevertheless was so, which was soon detected by many other plumbers present, besides myself, and after the close of the meeting on Friday night last I pointed out to Mr. Hellyer several little things with his models, which were in favour of the O-trap, but dead against the working of O-trap. Now, if models of two kinds are exhibited working as a test one against the other, each should have the same chance; this, however, was not the case, thus:—Mr. H. had a small O-trap, made with glass sides, to show that it was not self-cleansing, and was exceedingly pressing upon this point, so much so that he gained much applause from the inexperienced portion of his audience, who could not detect the unfairness in the construction of the two models, whilst other old hands at the trade, seeing the great disadvantage under which the O model was working, certainly did frequently interrupt the lecturer, for which they were decidedly hissed; but to prove that they were justified in interrupting, I must call your readers' attention to the following fact—viz., the first night, the basin supplying the water to the O trap, was much smaller than the basin supplying the S-trap; this was rectified on Friday night. Next there was the O-trap made about 4 in. high, or nearly half the height of the ordinary closet-trap, having only a 1 in. outgo (if really so much); the dip which was only 1 in. pipe, should have been at least 1½ in. or 2 in. internal diameter, as also the outlet pipe, for, according to Mr. Hellyer's own teaching, it should, if possible, be larger than the body of the trap. Fancy this dip, only a "one-inch" pipe, which of course did not allow a large enough body of water to enter the trap at one time, so as to drive out the foul water; but even besides this, it was very evident there was something else radically wrong. What was it? On examination I found a "bar" fixed across the basin-washer, which retarded and split the current of water, thereby causing an immense eddy, which, to say the least, would interrupt the flow to about one half. I arrived at this conclusion in the following way: Noticing that the water was an unaccountably long time in running from the basin into the trap, I requested Mr. Hellyer to place another three pints of water in the basin, and then timing it by a stop-watch, was convinced that the water had not a clear passage. Again, another point—the relative fall from the basins into the traps. The S model had an advantage of at least 4½ in. out of about 12 in., and by all the laws of gravitation this must mean at least one-third increase of pressure, even provided that each trap had the inlet and outlet in proportion.

Now, seeing how unfairly these two models have been placed before the trade, can it be wondered, when a large manufacturer of the O-trap is present and sees the too palpable blunder in the manufacture of the models, that he should interrupt? All I can say is that had he not done so, many hundreds of the young members of the trade would have gone home impressed with the idea that they had witnessed a legitimate test of the relative value of the two traps. Mr. Hellyer, however, at the close of the meeting, endeavoured to convince me that he was right by transferring the supply-basin from the O to the S-trap, and it acted all right; but that is not the point at issue. Now, if Mr. Hellyer will put inlet and outlet pipes, "full bore" to the O-trap as he did in his model of the S-trap, it will then be a fair test, but as done at his last lecture, radically wrong, and, I say, unjust.

Now we come to the highly important and sanitary point—Ventilation.

What does Mr. H. want plumbers to believe by these words? "If absolute safety was needed, the Eclipse, the Power, and even the O-trap, must be ventilated,"—he says, on account of the siphonage. Now, I agree with him that every trap should be ventilated; but I take an exception in the case of the O-trap, so far as siphonage is concerned, though all traps should be ventilated to prevent the decay that must take place through chemical action on the lead,

a most important point that, for some unexplained reason, Mr. H. has never, in the most remote way, made any reference to, or, at least, that I am aware of. So important, indeed, is it, that a well-ventilated trap will last twenty times as long as one not ventilated, as traps having no ventilation are condensers, and the action of the pent-up carbonic acid, in conjunction with this condensed water, sets up a very powerful corrosion, and the surface of the trap above the water-line becomes one mass of, so to speak, ulcers, and when, by the action of the closet, the water is disturbed in the trap, it dissolves this oxide of lead, then this solution, formed on these corroded or eaten parts, rapidly absorbs more carbonic acid, and thereby creates a quantity of hydrated oxy-carbonate of lead (PbO, HO + PbO, CO₂), which is deposited in white scales.

A word or two, by way of caution to plumbers, as to what Mr. Hellyer said about pumps drawing water 32 ft.; let me say that no pump-bucket in the world will act in any way satisfactory, even at his depth of 5 ft. less, i.e., 27 ft., 20 ft. being the maximum any plumber should fix a bucket from the surface of the water in the well. For my part, I rarely exceed 12 ft.

As a concluding remark on this subject, I would remind your readers that we Society Plumbers have never disputed that the O-trap has the best chance of clearing itself of any foreign substance, such as gravel, sand, or other matter that will not float, and not usually thrown down a closet; but, in cases where there is not a good flush of water, it may often be noticed that portions of the soil remain on the inlet side of the trap.

Now, one of the great advantages that the O-trap possesses over the S-trap is, that it allows the soil much more readily to pass to the other side of the trap, where it is little or no consequence, and any common-sense person must know that this is better than floating about (as is very frequently the case) on the dip or pan side of the trap.

If the O-trap is so self-cleansing as Mr. H. has shown in his small glass models, why are nearly all small-sized O-traps made with cleansing-caps and screws, which we plumbers frequently have to open, to clear them of small pieces of soap, and other matters.—I am, &c.,

P. J. DAVIES, Hon. Mem. A.S.P., &c.

BUILDING-STONES.

SIR,—I can understand and respect Messrs. Pictor and Sons' partisanship for their Box-ground stone, but they have overlooked my point. As a weather stone, i.e., in the usually received sense of the term, ability to stand frost, I willingly allow their Box-ground stone the characteristic of excellent, supposing it to be quarried under right conditions, and that its natural bed be scrupulously retained. But what I maintained, and must continue to do, is that of all the Bath oolites the Box-ground is most affected by the steady action of a south-west exposure to severe storms, a damp climate, or a chemically affected atmosphere. The coarseness of the grain or quality of this stone is against the formation of that permanent glaze or case-hardening which, as I explained in my last letter, is the result of working the oolites fresh from the quarry, such being really the case with all stones in a greater or less degree.

I can well understand the process of slow and sure destruction is not so observable in the generally sheltered localities of the counties of Wilts and Somerset, the climates of which are amongst the driest in England; but I am quite sure that if an impartial examination be made of any of those buildings erected of Box-ground stone more than 20 years ago, and in positions to be affected by the conditions I have described, they will find the grading process steadily at work. In London this is, to a degree, most distressingly manifest; no one of any feeling or who possesses a genuine love for good, enduring work, can walk a mile in any direction, without having aroused in himself feelings almost of hatred—if I may be allowed to use the expression—against the persevering use of a stone so utterly wanting in all those qualities required, if the purposes of architecture is to be fulfilled—that of being a joy and a teaching to men—the actual reflex of the mind of the artist, and his expression of the honour and glory due to the Creator, or to himself, according to the principle from which he works.

One writer refers to the Grosvenor Hotel, Victoria, as being built of Corsham stone. A careful examination of this building confirms me in my belief, as expressed in my last letter, that this stone is the most lasting, if worked under the conditions I stated. I was particularly pleased to find that, so far, the hotel shows no signs of being anywhere affected by the trying London atmosphere. If such has been the result under the ordeal of the cleaning-down system, we may look for much more favourable results when this stone is allowed to protect itself by its own natural weather coat.

At the risk of making, I am afraid, my letter rather too long, I should wish to make one more remark upon the stone to be used in Truro Cathedral.

Would, that before finally closing the question, the committee could give the following principles their full weight and value, underlying as they do all true growth in architecture: That the building completely fulfil modern requirements; and that, used with all the skill and experience which modern science can supply, the very happiest results will follow upon using those materials which are the readiest to hand, and consequently the most available.

In Mr. Pearson's hands, than whom to my mind no architect of modern days has so thoroughly solved the problem of giving dignity and real character to his buildings by the use of the simplest materials, I am thoroughly convinced that the Cornish granite—a stone admirably expressive of the steady persevering character of Cornishmen, and characteristic of the ruggedness of their country, will readily assume and fulfil that thorough adaptation of means to an end, which is one of the first principles of successful designing. For a proof of this, I need only point to that admirable work, the Thames Embankment, than which no grander result has been obtained in this country, from following simple first principles.

What is the object of a cathedral but to express in the highest and stateliest manner possible, the principles of the religion of its founders?

We, as followers of that branch of the Church Catholic, the Church of England, do not need to be informed what our principles are: they are embodied in this text, "In quietness and in confidence shall be our strength." Simplicity, then, and dignity only are the characteristics required externally; and internally all is to bear the stamp of the "beauty of holiness," viz., the adornment of God's house by the appellation of all we hold most precious and most valued of the arts with which our bounteous Creator has so richly endowed us.

Used internally, Caen-stone, as a decorative stone, stands very high. Coming to be used, as it thus would, for window tracery, I believe the contrast with the granite would prove highly satisfactory, especially when time shall have toned down the vividness of the colouring of the two stones.

Trusting you may be enabled to find space for these few further remarks—I am, &c.,

July 6th.

DURABILITY.

SIR,—During a recent visit to King's College, Camb., I was surprised to find the recently-erected fountain showing such early evidences of decay. Whoever is responsible for the use of the cheap and inferior class of Portland stone used, I feel, will regret the folly of selection.

The west block of the quadrangle, erected in 1724 of Portland stone, and the magnificent chapel, erected during the intervening years from 1416 to 1515, of Barnack and Riche Abbey stone, are in a better state of preservation than the recently-erected fountain of two years ago.

Sir Christopher Wren stipulated in the conditions regarding the stone to be used in St. Paul's Cathedral, namely, each block to be subjected to five years' exposure on the coast previous to being shipped to London. Hence, we have a building in good preservation, although some of more recent time are in a state of decay.

Some reliable work on the history and behaviour of building-stones, under the varied conditions of the atmosphere in the towns of England, would be of immense value to the architectural profession, and could be readily obtained from the buildings of historic interest in every county.

Possibly, Mr. Armistead, R.A., the eminent sculptor, can account for the above unfortunate circumstance. An explanation will be of interest to the readers of your valuable journal during the present controversy regarding building-stones.—I am, &c.,

CANTAB.

SIR,—I should not have thought it worth while to further trespass on your valuable space had not Mr. Masey challenged the correctness of the fact of the specimens submitted by me to Mr. Kirkaldy being representative of my "Monks' Park Quarry." I affirm that they were fair and reliable samples taken from different beds, and not from a "hard bed" which Mr. Masey knows of, as that class of stone does not appear in my quarry.

Mr. Masey says, "it is not agreeable to common-sense to suppose that Mr. Sumsion's quarry is so different to all the rest of the oolitic deposits." As a matter of fact it is different, as all the beds throughout this quarry are as near as possible of one uniform colour and texture. Of this assertion Mr. Masey may convince himself by a personal visit.

In conclusion, I would say that most of the examples I mentioned of old buildings are either city or suburban. I could quote very many others were it necessary.—I am, &c.,

ISAAC SUMSION.

Bath Stone Office, 4 and 5, Newark-street,
Bath, 5th July.

SIR,—In reference to Mr. Trickett's remark, I beg to say that I do consider, in point of durability, that Beer stone is equal to any. The facts relative to the chapel at Westminster fully justify my assertion. I also wish architects to inspect the specimen of Beer stone in Holborn, as I assert there is nothing otherwise than pleasing in its appearance. In London, where in a few months everything is coated with soot, original tints, even if objectionable, are but of little consequence. But whether new or old, I prefer the appearance of Beer stone to what seems at the present time to be the favourite—Portland. Its patchiness of colour, as may be seen at the new Government Offices at Whitehall, interfering with the lines and light and shade of the architecture, deteriorates much the general effect. Some Gothic architects like patchiness, but in Classic architecture colour should be uniform.

Messrs. Pictor, I see, assert that "Box-ground" endures "under the most trying circumstances." Such is not my experience. I last week visited a celebrated house at Kensington. The balustrades, of ordinary Bath stone, were much decayed, and the main building, which is of "Box-ground," in two or three dozen places was showing signs of decay. Kensington is, I should say, a favourable place, whilst Holborn is the reverse. Yet Beer stone in the house-front in Holborn shows no sign of decay, though built at the same time as the mansion I have referred to in the better situation. Facts are stubborn things. Here are a couple which cannot be explained away. Bath stone, as at Buckingham Palace, cannot be safely used in London without painting it. This, whilst considerably adding to expense, takes away the character of stone. Cement might just as well, or in fact had better, be used: it is the superior material.—I am, &c.,

PHILIP E. MASEY.

24, Old Bond-street, W., July 6.

LONDON BUILDINGS.

SIR,—I have read in your ever-interesting columns the articles treating about the above, and emanating without a doubt from a sagacious pen.

May I be allowed to submit a suggestion of a point, which it seems has not been sufficiently touched upon?

A far greater blame and want than that of style and taste, or scale, is that in the use of materials. For what is the finest style and ornament, if executed in an unfit material? I will not venture, by enumeration of the latter, to raise controversies, but leave every one to form his own judgment from the facts before us. Look at the countless buildings in the main arteries of our metropolis: what an aspect their exterior presents! Parapets, balustrades, and cornices in a threatening condition, with their "bones" sticking out and saw-like edges, brackets, cappings, courses—all vying with each other in decaying, scaling off, and crumbling.

And what a legion of other buildings there exists, in the finest quarters too, where oil-paint, finger-thick levelling, and filling up in many cases what there is of bosses and enrichments, tides them over a number of years, till one neglect of the brush seals their fate too.

And all this in a climate which is known to put materials to the severest test, to which even some of the most durable succumb.

That class of buildings above alluded to cannot fail to be a disgrace to their constructors, a disfigurement to the metropolis, and an injury to our nation, which is renowned throughout the world for its substantial turn of mind and soundness of taste.

Let us, therefore, endeavour to dam this over-growing evil, and to build more "not for an age, but for all time."—I am, &c.,

MATERIALIST.

COMPETITIONS.

SIR,—In last week's issue of the BUILDING NEWS, "A Believer in Honest Competitions" tries to induce competitors to refrain from venting their grievance in your columns. In the particular case, viz., the Winchcombe School competition to which he refers, I quite agree with him in deprecating the correspondence which has taken place.

I was a competitor, and, as far as I know, the competition was carried out in a straightforward and satisfactory manner. I was also a competitor for the new church at Windermere; but the arrangements were not satisfactory, and this is what I wish particularly to bring before your notice—not from any personal feeling in the matter, but from a conviction that the unfair treatment which competitors are occasionally subjected to is to be remedied by publicity alone.

The designs were sent in, carriage paid, on the 11th June, and about three weeks after I received the printed circular inclosed.* This is all the information that has been deemed sufficient for competitors to have, and besides the insult of leaving unsuccessful competitors in ignorance of the successful architect, an injury was inflicted when the drawings were returned, the cost of carriage unpaid. More than a week since I wrote to the chairman of the committee asking for information; but my temerity in doing so has been treated with the silent contempt that I suppose he thinks it merits.—I am, &c.,

QUID.

CLERICAL COURTESY.

SIR,—I don't know what you think about the inclosed circular, but I think it is cool impertinence not even to say whether a design has been selected, and if so, whose.—I am, &c.,

"ONE OF THE FOOLISH."

Windermere Rectory, June 20, 1881.

DEAR SIR,—By desire of the Committee I beg to return, with their best thanks, the Plans sent by you for the New Church at Windermere.—I am Sir, your faithful servant.

EDW. P. STOCK.

THE WOOD-CARVING AT THE HOUSE OF LEOPOLD ROTHSCHILD, ESQ., HAMILTON-PLACE, W.

SIR,—Through the kind influence of Mr. I. Jackson, of the firm of Messrs. Jackson and Son, Rathbone-place, Oxford-street, the woodcarvers of London obtained special permission last Saturday afternoon, from 3 to 5, to see the woodcarving at the house of Leopold Rothschild, Esq. Two hundred cards for admission were distributed by the Secretary of the Society of Woodcarvers, the majority of whom visited the house in Hamilton-place on Saturday, and expressed their admiration of the work that has been done. The work in the library, done by Italian woodcarvers, well sustains their character, both for design and execution; at the same time great credit is due to the firm of Messrs. Jackson and Son for the work that has been done by them, and will bear favourable comparison with any work in that style. In fact, the whole of the work, so far as we were able to judge on Saturday (not forgetting the marble-carving by Mr. Forsyth, and plaster decorations of the upper rooms by Messrs. Collinson and Luck), deserve great praise, and was very much admired. We hope to be allowed to see the work again when everything is finished.—I am, &c.,

W. SANDLANDS,

Secretary, Society of Woodcarvers,
119, Great Titchfield-street.

* The circular is identical with that appended by another correspondent.—Ed.

THE RECENT ELECTION AT THE ROYAL ACADEMY.

SIR,—I still think "A. B." is incorrect in saying that "it seems to be particularly the case with regard to architecture that men of distinguished merit are passed over by the R.A., and others of less note are elected."

After the insinuations in his letters, it is quite unnecessary for him to dispute with me whether the present list of architectural Academicians and Associates does or does not contain the names of second-rate men.

He "wonders upon what possible grounds the recent election can have been made," with three such men as those he names standing outside the door. I contend the new A.R.A. is in every sense an architect; and, moreover, he is a leading artist, and that these are the grounds upon which he was elected.

I am sorry that it should be necessary to explain this; but so it seems that such as he are not as generally known as those who are in a "large way of business," and I suppose this is the reason why "many persons outside the world of artists are in much amazement."

I quite think it to be a question of artistic ability, yet I could not help expressing a regret that in our Academy of Arts Classic work is not properly represented by architects.—I am, &c.,

ONE WHO WAS NOT SURPRISED.

29th June.

Intercommunication.

QUESTIONS.

[6558.]—**Staircasing.**—Will some one kindly give list of some reliable works on staircasing, with prices, particulars, and opinion of same?—SNAWSEBURY.

[6559.]—**Assize Courts.**—Would any architects who have built assize courts, kindly give the cost in round numbers, for the information of the querist? Durham has been named as a good example as to arrangement, cost, ventilation, &c. Perhaps the architect would be good enough to reply to this.—SPENCER.

[6560.]—**Bearing Loads.**—Will you kindly inform me, through your columns, a safe formula for calculating the safe bearing load for a cross stanchion in section (cast iron)? I should also be glad to know which is the best method for calculating safe loads for cast iron columns, and H and I stanchions. Is there a calculator published which will give this?—ENOXBOROUGH.

[6561.]—**Well Pudding.**—Having sunk a well and steened same with 1½ in. ring, I now wish, by puddling, to effectually exclude all surface-water, &c. Will some reader kindly tell me what thickness of clay is required, how much more brickwork there should be in the rings, and whether the same should be in cement or mortar? The well is 35ft. deep, and the stratum of clay commences at a depth of 18ft.—CONWAY SUBSCRIBER.

[6562.]—**Defective Rain-Water Tank.**—A circular tank, 7ft. diameter and about 5ft. deep, leaks, hard water percolates through the sides, and renders tank of no use. The sides are 1½ in. brickwork, and puddled behind with clay. Portland cement has been tried, and will not answer; also a mixture of plaster and cement. Wanted to know any method of cementing the tank so as to avoid digging down outside the brickwork, or the use of asphalt as being too expensive.—THE USER.

[6563.]—**Durer's Works.**—Where can I obtain reproductions of Durer's drawings and paintings? Some have, I know, appeared in your journal. A reference to biographical notice or book will also oblige.—G. W. T.

REPLIES.

[6549.]—**Portland Cement Mouldings and Flat Surfaces.**—I am thankful to "Plasterer" for his reply, which is well put and useful, but not to the point required. The work is finished, and the information sought is—What composition as a preservative should be applied that would not have the oily look of paint, a composition that will act as a preservative and leave the cement surfaces more of a transparent and stone-like appearance.—STONE FINISH.

[6551.]—**Decoration.**—I would recommend "Occupier" to select a dado in which the lighter ground-colour was of a cream tint. A shade or two darker might be better, and the pattern would harmonise very well if it was a warm citron or chocolate colour, of course darker in tone than the wall-paper.—G. H. G.

The completion of the first section of the proposed enlargement of St. Peter's Church, Bedford, was celebrated on Wednesday week: it consists of an extension of the north aisle, providing 50 additional sittings. The arcade and window-dressings are of Corsham Bath stone, and the roof is higher than that over older portion of aisle. Mr. J. Piers St. Aubyn, of London, was the architect, and Mr. William Osborne, of St. Neot's, Hunts, the contractor; the cost was about £350. The other contemplated works include new organ-chamber and vestry, lengthening of south aisle, adding a staircase turret to the central tower, and removal of pulpit to new position.

The *Liverpool Journal of Commerce* says it is expected that a large quantity of Canadian cement will be shipped to Europe this fall.

LEGAL INTELLIGENCE.

LIABILITY OF CONTRACTORS TO MAKE GOOD DAMAGE TO ROADS.—Mr. Alexander Glen, barrister, of London, has had a case submitted to him by the Stratford-on-Avon Highway Board as to the liability of owners, contractors, or sub-contractors to make good damage to public roads caused by excessive traffic. Mr. Glen's opinion just given is interesting to public bodies throughout the kingdom. The Board's case is somewhat peculiar and complicated. Mr. Carlile, a large landowner, of Grafton, a parish about six miles from Stratford-on-Avon, in 1878 commenced to build a large mansion, which has since been completed. Mr. Lovatt, of Wolverhampton, being the contractor, the bricks being supplied from Mr. Espley's brickyard, at Stratford, and were delivered by carts belonging to different persons, including some Grafton farmers, and also by Messrs. Ball and Horton, who used a traction-engine, with broad-wheeled road-trucks. The roads leading from the brickyard to Grafton are under the management of the Board. The surveyor of the Board certified that the expense of the repairs of the road in question in 1879 exceeded by £116 5s. 10½d. the average cost of the two preceding years. Counsel was informed that a provisional order had been made for the dissolution of the Board, but it had not yet been confirmed, nor, if it be confirmed at the ensuing Sessions, to be held in July, could it yet be settled at what date the dissolution would take place. Counsel was requested to advise the Board (1) whether they had a right, under section 23 of 41 and 42 Vic., c. 77, or otherwise, to compel the payment of any sum of money, and if so, by whom and what process? (2) To advise the Board as to what steps they had better take under the circumstances. Mr. Glen's opinion on the case is as follows:—(1) "If it appears from the surveyor's certificate, and can be proved, that the excess of the expenditure on the roads in 1879 over the expenditure on them in previous years was due to the carting of bricks for Mr. Carlile's house, both in carts and trucks, drawn by a traction engine, they are in my opinion entitled to recover such excess from the person or persons 'by whose order' the traffic was conducted, under section 23 of the Highways and Locomotive (Amendment) Act, 1878. It is suggested that the traffic was conducted 'by the order,' within the meaning of that section, of (a) Mr. Carlile, for whom the house was built (b) Mr. Lovatt, the builder, who contracted to erect the house; (c) Mr. Espley, who supplied the bricks; or, (d) Messrs. Ball and Horton, and others, who, as I understand, contracted with Mr. Espley, to carry the bricks from his brickyard to the site of the house. Now, in the case of Williams v. Davies (44, J. P. 347), where a timber merchant bought timber near a railway station, and contracted with carriers for the carriage of it to the station, it was held that the merchants, and not the carriers, ought to repay the extra expenditure on road repairs rendered necessary by reason of the carriage of the timber. Now, it was for the benefit of Mr. Carlile, and it was a necessary incident to the orders which he gave and which the builder agreed to carry out, for the erection of the house, that the bricks were carried over the road; and, although the point is not free from doubt, I think that, on the principle of the above case, Mr. Carlile cannot escape his primary liability under the section because he employed a contractor to do all that was requisite (including the carriage of the bricks) for the erection of the house, or because the contractor carried out his contract, through sub-contractors, in such a manner as to damage the roads. (2) The dissolution of the district not being completed, the provisional order for its dissolution need not prevent the Highway Board from proceeding to recover the expenses in question summarily before the magistrates, at petty sessions; and I think that such proceedings should rather be taken against Mr. Carlile than against any of the other persons above-mentioned—(Signed) ALEXANDER GLEN, 4, Garden-court, Temple." Should Mr. Carlile decline to pay the amount demanded by the Board, viz., £116 5s. 10½d., the clerk has been instructed to take legal proceedings against him to enforce payment.

IN RE C. SAMUELS.—The bankrupt, carrying on business as a builder at East Dulwich, applied on Tuesday to pass his public examination. His balance-sheet showed liabilities amounting to £1,770; fully-secured debts, £1,850; with assets, inclusive of a large estimated surplus from property in the hands of secured creditors, £2,919. The bankrupt, after some opposition, passed his examination.

BIG BEN AND SIR EDMUND BECKETT.—STAINBANK v. BECKETT.—The trial of the action of libel against Sir Edmund Beckett for statements published in the *Times*, having reference to the founding of Big Ben, was concluded on Tuesday in the Queen's Bench Division of the High Court of Justice. Mr. Baron Huddleston, in summing up the case to the jury, went fully and carefully into the history of the bell, its casting, and defects; likewise into the history of the former action and of the present. There were three several letters or statements which

the jury would have to consider—viz., (1) the letter of the 31st of October, 1878, in which the defendant had said that Big Ben was a disgrace to its founders; (2) the letter of the 20th November, 1878, in which the expression "oldest and worst of the foundries in England" occurred; and (3) the letter of January, 1879, in which the defendant repeated his charge against Mears, but disavowed any intention of referring to the plaintiff. As to each of these, he would put three questions to the jury:—(1) Were the words libellous in themselves? (2) Were they libellous of the plaintiff? (3) Did they exceed fair comment upon matters of public interest? The jury, after an absence of about three-quarters of an hour, returned an affirmative answer to these questions in respect of the letter of the 20th of November, 1878, only, and awarded to the plaintiff damages £200.

ALLEGED INFRINGEMENT OF GLAZING PATENT.—(Before Lord Rutherford Clark, in the Outer House at Edinburgh, on June 24.)—S. and I.—The Pennycook Patent Glazing and Engineering Company (Limited) v. Mackenzie, Harley, and Co.—The Lord Ordinary was engaged recently hearing evidence in this case, in which the complainers, a Glasgow Company, asked interdict against the respondents, engineers, Hope-street, Glasgow, infringing letters-patent granted to the pursuers in May and November, 1879, for the invention of "new and improved constructions of self-glazing or glass-fixing sheet-metal bars for window-sashes, roof, and frame-lights for green-houses, garden-frames, vineries, conservatories, sheds, and other structures, where glass was required for the admission of light." The defence was a denial of the validity of the pursuers' patent, and, assuming its validity, of the alleged infringement of it. His Lordship has now issued an interlocutor, in which he assizes the defenders from the conclusions of the action, and with expenses. In a note to his interlocutor, he says: The patent is assailed on various grounds. But after the proof, it was evident that the only important challenge depended on the allegation that, before the provisional specification was lodged, the patentee had himself published the invention by exhibiting the patented articles at the show of the Glasgow Agricultural Society on 7th, 8th, and 9th May, 1879. In the opinion of the Lord Ordinary, the allegation has been proved. If the witnesses for the respondents are speaking the truth, it is plain that the patent is bad, and the Lord Ordinary sees no reason to doubt either their accuracy or their honesty. After the evidence of the respondents was closed, the complainers asked for an adjournment to lead proof in replication that they had received explicit notice on record, and that they had entered on the point in their evidence-in-chief. The Lord Ordinary refused the motion. He did not think it right that the complainers should have an opportunity of seeking out the evidence with which they should have been prepared at the beginning of the case. If the Lord Ordinary is right, so far of course there is an end. But even if the patent were valid, he is of opinion that there has been no infringement.

STATUTES, MEMORIALS, &c.

THE SCOTT MEMORIAL.—The memorial to the late Sir George Gilbert Scott, in the form of a brass, is now being laid over his grave in the nave of Westminster Abbey. The Dean will uncover the same on Wednesday next, the 13th July, at 12 o'clock, and it is hoped that a few of Sir Gilbert's old friends will be present. The memorial has been erected by public subscription. The brass, already illustrated in our pages, was designed by Mr. Geo. Edmund Street, R.A., and has been executed by Barkinton and Kraal, of Regent-street. The marble work was undertaken by Messrs. Farmer and Brindley.

NEW STATUES.—A new statue of Mr. Gladstone, executed by Mr. Albert Bruce Joy, will very shortly be sent to the foundry at Thames Ditton, and when cast in bronze, will be set up in the east end of London. It is presented to the citizens of London by Mr. Theodore Bryant, of the firm of Bryant and May, and is over 9ft. in height. Mr. Gladstone is represented standing in the act of delivering an address. The costume is the ordinary morning dress of the 19th century gentleman, with the addition of a loose overcoat, thrown open in front. The work has been seen by a great many people, and last week Mr. Joy was honoured by a visit from the Prince of Wales. Sir Stafford Northcote, Mr. Bright, Mr. W. H. Smith, Lord John Manners, and other Members of Parliament have also inspected the statue, for which Mr. Gladstone sat a few weeks ago.—The Harvey Centenary Memorial statue, in bronze, which was sent to the South Kensington Museum for the *consecrazione* of the Harveian Society, has now returned to Mr. Joy's studio, where it will remain until the unveiling, which will take place at Folkestone (Harvey's birthplace) on the 6th of August, during the great international meeting of medical men which takes place in London this year. This statue is also of colossal size.

Our Office Table.

A PRIVATE visit was paid to the Channel Tunnel experimental works at Abbot's Cliff, on Saturday week, by the chairman of the South-Eastern Railway Company and a party of scientific and other gentlemen. Very satisfactory progress was found to have been made with the boring operations since the last visit, the heading having been advanced to a total length of upwards of half a mile. The tunnel is kept perfectly free from any accumulation of water by the pumps, and a good average rate of advancement in the boring is maintained. There is no alteration in the nature of the strata. The work at the new shaft at Shakespeare's Cliff promises to be even more successful, a very superior boring machine being used. The progress of the work is considered satisfactory.

The annual meeting of the members of the Association of Municipal and Sanitary Engineers and Surveyors is being held at Birmingham, yesterday, to-day, and to-morrow. At noon, yesterday, the election of officers and other association business was transacted, after which the president delivered his inaugural address. The outfall sewage-works and the sewage-farm at Salford were then inspected, and also the intercepting works in Montague-street, both of which were explained by the borough surveyor. The annual dinner took place in the evening at the Queen's Hotel. To-day there will be a discussion upon the local works visited the previous day, and papers, which will be read. To-morrow the Corporation Gas and Water Works will be visited and inspected.

We announced, recently, that Mr. T. Roger Smith was a candidate for the appointment of Professor of Architecture at University College. Mr. Roger Smith has been appointed, and at the same time the council of the college have marked their sense of Professor Lewis's past services by appointing him Emeritus Professor.

We may once again remind readers that the Parkes Museum of Hygiene International Medical and Sanitary Exhibition is to be held at South Kensington, from July 16th to August 13th. The opening ceremony takes place at the Royal Albert Hall on Saturday, July 16th. The President, the Right Hon. Earl Spencer, K.G., will take the chair at 4.30 p.m., supported by the Right Hon. Earl Granville, K.G.; the Right Hon. John G. Dodson, M.P.; Sir James Paget, Bart., D.C.L., LL.D., F.R.S.; and Mr. John Eric Erichsen, F.R.S.

THERE is every reason to believe that the Fine Art Exhibition to be held in the New Infirmary, Bolton, during the approaching autumn will be a great success. About a thousand pictures, including many important works by well-known artists, have already been promised, also the loan of collections of objects of interest, which will be exhibited in some of the smaller rooms. Among these will be examples of the best old and modern china, both English and foreign, old armour, tapestries, and manuscripts. The Science and Art Department, South Kensington, are also sending a valuable contribution, which will fill one of the large rooms. Any further offers of the loan of articles for exhibition should be made at once, as the committee are busy with the classification of the various departments. The exhibition will be opened in September, remaining open for about three months, during which time, among other attractions will be a number of musical and other entertainments.

The thirtieth annual meeting of the Birkbeck Building Society was held yesterday (July 7th) in the Theatre of the Birkbeck Literary Institution. The report presented to the meeting stated that the receipts for the year ending 31st March last were £7,117,563, or an increase of £1,137,831 over those of the previous year, and the total for the commencement of the society, £56,912,588. The deposits reached the large sum of £5,789,088. The gross profits earned by the society amounted to £108,721, of which £89,759 have been appropriated to the payment of interest on shares and deposits, discount, and expenses of management, leaving a net profit of £18,962, which, added to the previous balance, £14,281, up the total of undivided profits to £33,243. The dividend for the year ending 31st March last was 10s. 6d. per share, or 10s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 21s. 12d. per share, or 21s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 32s. 6d. per share, or 32s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 43s. 12d. per share, or 43s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 54s. 6d. per share, or 54s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 65s. 12d. per share, or 65s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 76s. 6d. per share, or 76s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 87s. 12d. per share, or 87s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 98s. 6d. per share, or 98s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 109s. 12d. per share, or 109s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 120s. 6d. per share, or 120s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 131s. 12d. per share, or 131s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 142s. 6d. per share, or 142s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 153s. 12d. per share, or 153s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 164s. 6d. per share, or 164s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 175s. 12d. per share, or 175s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 186s. 6d. per share, or 186s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 197s. 12d. per share, or 197s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 208s. 6d. per share, or 208s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 219s. 12d. per share, or 219s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 230s. 6d. per share, or 230s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 241s. 12d. per share, or 241s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 252s. 6d. per share, or 252s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 263s. 12d. per share, or 263s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 274s. 6d. per share, or 274s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 285s. 12d. per share, or 285s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 296s. 6d. per share, or 296s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 307s. 12d. per share, or 307s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 318s. 6d. per share, or 318s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 329s. 12d. per share, or 329s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 340s. 6d. per share, or 340s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 351s. 12d. per share, or 351s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 362s. 6d. per share, or 362s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 373s. 12d. per share, or 373s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 384s. 6d. per share, or 384s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 395s. 12d. per share, or 395s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 406s. 6d. per share, or 406s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 417s. 12d. per share, or 417s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 428s. 6d. per share, or 428s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 439s. 12d. per share, or 439s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 450s. 6d. per share, or 450s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 461s. 12d. per share, or 461s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 472s. 6d. per share, or 472s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 483s. 12d. per share, or 483s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 494s. 6d. per share, or 494s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 505s. 12d. per share, or 505s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 516s. 6d. per share, or 516s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 527s. 12d. per share, or 527s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 538s. 6d. per share, or 538s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 549s. 12d. per share, or 549s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 560s. 6d. per share, or 560s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 571s. 12d. per share, or 571s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 582s. 6d. per share, or 582s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 593s. 12d. per share, or 593s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 604s. 6d. per share, or 604s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 615s. 12d. per share, or 615s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 626s. 6d. per share, or 626s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 637s. 12d. per share, or 637s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 648s. 6d. per share, or 648s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 659s. 12d. per share, or 659s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 670s. 6d. per share, or 670s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 681s. 12d. per share, or 681s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 692s. 6d. per share, or 692s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 703s. 12d. per share, or 703s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 714s. 6d. per share, or 714s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 725s. 12d. per share, or 725s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 736s. 6d. per share, or 736s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 747s. 12d. per share, or 747s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 758s. 6d. per share, or 758s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 769s. 12d. per share, or 769s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 780s. 6d. per share, or 780s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 791s. 12d. per share, or 791s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 802s. 6d. per share, or 802s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 813s. 12d. per share, or 813s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 824s. 6d. per share, or 824s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 835s. 12d. per share, or 835s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 846s. 6d. per share, or 846s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 857s. 12d. per share, or 857s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 868s. 6d. per share, or 868s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 879s. 12d. per share, or 879s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 890s. 6d. per share, or 890s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 901s. 12d. per share, or 901s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 912s. 6d. per share, or 912s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 923s. 12d. per share, or 923s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 934s. 6d. per share, or 934s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 945s. 12d. per share, or 945s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 956s. 6d. per share, or 956s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 967s. 12d. per share, or 967s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 978s. 6d. per share, or 978s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 989s. 12d. per share, or 989s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1000s. 6d. per share, or 1000s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1011s. 12d. per share, or 1011s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1022s. 6d. per share, or 1022s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1033s. 12d. per share, or 1033s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1044s. 6d. per share, or 1044s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1055s. 12d. per share, or 1055s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1066s. 6d. per share, or 1066s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1077s. 12d. per share, or 1077s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1088s. 6d. per share, or 1088s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1099s. 12d. per share, or 1099s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1110s. 6d. per share, or 1110s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1121s. 12d. per share, or 1121s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1132s. 6d. per share, or 1132s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1143s. 12d. per share, or 1143s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1154s. 6d. per share, or 1154s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1165s. 12d. per share, or 1165s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1176s. 6d. per share, or 1176s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1187s. 12d. per share, or 1187s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1198s. 6d. per share, or 1198s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1209s. 12d. per share, or 1209s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1220s. 6d. per share, or 1220s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1231s. 12d. per share, or 1231s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1242s. 6d. per share, or 1242s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1253s. 12d. per share, or 1253s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1264s. 6d. per share, or 1264s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1275s. 12d. per share, or 1275s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1286s. 6d. per share, or 1286s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1297s. 12d. per share, or 1297s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1308s. 6d. per share, or 1308s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1319s. 12d. per share, or 1319s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1330s. 6d. per share, or 1330s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1341s. 12d. per share, or 1341s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1352s. 6d. per share, or 1352s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1363s. 12d. per share, or 1363s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1374s. 6d. per share, or 1374s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1385s. 12d. per share, or 1385s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1396s. 6d. per share, or 1396s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1407s. 12d. per share, or 1407s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1418s. 6d. per share, or 1418s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1429s. 12d. per share, or 1429s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1440s. 6d. per share, or 1440s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1451s. 12d. per share, or 1451s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1462s. 6d. per share, or 1462s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1473s. 12d. per share, or 1473s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1484s. 6d. per share, or 1484s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1495s. 12d. per share, or 1495s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1506s. 6d. per share, or 1506s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1517s. 12d. per share, or 1517s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1528s. 6d. per share, or 1528s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1539s. 12d. per share, or 1539s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1550s. 6d. per share, or 1550s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1561s. 12d. per share, or 1561s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1572s. 6d. per share, or 1572s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1583s. 12d. per share, or 1583s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1594s. 6d. per share, or 1594s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1605s. 12d. per share, or 1605s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1616s. 6d. per share, or 1616s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1627s. 12d. per share, or 1627s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1638s. 6d. per share, or 1638s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1649s. 12d. per share, or 1649s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1660s. 6d. per share, or 1660s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1671s. 12d. per share, or 1671s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1682s. 6d. per share, or 1682s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1693s. 12d. per share, or 1693s. 12d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total of 1704s. 6d. per share, or 1704s. 6d. per £100, which, added to the previous dividend of 10s. 6d. per share, or 10s. 6d. per £100, makes a total

THE BUILDING NEWS.

LONDON, FRIDAY, JULY 15, 1881.

VARIATIONS AND ADDITIONS.

ONE of the responsibilities incurred by the architect is that of ordering alterations and additional works, and there is no other part of a building contract which causes him so much uneasiness and anxiety in the adjustment of the accounts. An employer places implicit confidence in his architect; he believes, and not unreasonably, that the plans and specifications have been prepared with every regard for the completeness of the building, notwithstanding probably his own inability to see that certain requirements have been duly incorporated in those documents. It happens frequently that each party has put too much confidence in the other. The architect believes his plans represent his client's wishes in every essential point. The employer, full of expectation, thinks his professional adviser could not have misled him, while the builder interprets the meaning of plans and specifications in a sense different from both, and with an evident desire to conform so close to their letter, that it is better to omit what is not clear than to do too much. A contractor is not much given to inference, though in every well-drawn contract he is enjoined to carry out all work which, in the opinion of the architect, may be fairly inferred from the plans and specifications, even though not clearly specified. The shortcomings of the architect, and the close-shaving of the contractor, rarely reach the anticipations of the employer, so that all three are occasionally disappointed. It is much to be regretted that clients who have little or no knowledge of building, and cannot read a set of plans, do not consult someone who can advise them, or, at least, take the trouble to read one of those guides addressed to laymen who are about to dabble in bricks and mortar. Want of the plainest knowledge of the subject has led to the bitterest disappointments, and it is such lack of experience which has given the old adage such point that "Fools build houses, but wise men live in them." If clients made their wants intelligible, and architects took a little more trouble in explaining the effect of their plans, and were to read their specifications over to their clients, there would not be so many of those troublesome things called "extras" to face.

As so much depends on the written contract, however, it may be as well to see how the usual clause introduced to meet alterations and additions stands, and whether it really is the instrument it pretends to be in protecting the employer. It may be postulated (1) that necessary "extras" should be ordered; and (2) that they ought to be paid for. In effect the usual clause runs thus:—"That no extra work is to be executed without the authority of the architect in writing, or in any plan or drawing expressly given and initialed by him. Any variation made in carrying out the works is not to vitiate the contract, but the value of such variation is to be ascertained by measurement, unless a price may have been previously agreed upon." There is generally a reference made to a schedule of prices, according to which all additions or omissions are to be valued, though, curious to say, the latter are generally estimated at a lower rate. It has been objected, and not without reason, that this clause places the entire control of extras and variations in the architect's own hands, and that the employer is kept in

ignorance of them till he is called upon to defray their expense. It also enables the architect to strike out matters which the employer had sanctioned: to vary the dimension and design. As we know, in some cases this power may be wielded in a manner detrimental to the proprietor: some things may be set off against others, as, for instance, things may be struck out to make room for omitted work. Let us suppose an instance by no means uncommon. There is a deficiency discovered in the quantities; let us say that the flooring has been found short, or the kitchen-dresser has been omitted. The contractor informs the architect of the fact, but he does not like to give another order, so he arranges with the contractor to omit, as a set off, the espagnolette casement fastenings, or some other fitting which the employer had particularly desired. When the house is finished the client finds the omission, and gives another order for the very thing he has already paid for. In many contracts these occurrences are not uncommon, though they frequently lead to unpleasantness and not a little embarrassment on the part of the architect. Somehow or other also things ordered as "extras," unless valued at once and their cost ascertained, grow to large proportions at the end of the work. Tendering at the beginning and valuation at the conclusion of a job are vastly different transactions with some builders, and an "extra" which has been strongly recommended by the builder with the assurance that it will only cost a few shillings, and add greatly to the convenience and comfort of a house, often comes to as many pounds.

Sir Edmund Beckett, in his "Book on Building," very strongly urges the adoption of a clause which makes it necessary for an architect to obtain the consent of the employer before an extra is ordered, and we may quote it here, as many readers have probably not seen it. "The contractors shall also execute all such alterations and additional works as shall be ordered by the architect with the consent of the committee, or by the committee. But if the contractors shall be of opinion that any such alteration or addition will cause additional expense, they shall not be bound to execute the same without an order in writing from the committee, stating the price which is either agreed on or certified by the architect as the proper sum to be allowed for the same, after giving credit for the value of any omissions which have been ordered, and such order shall state also the extension of time (if any) which is to be granted by reason thereof. And neither the contractors nor sub-contractor under them shall be entitled to recover from the committee, or any member thereof, any more than the said sum of £—, together with the amount of the sums contained in all such orders as last aforesaid; nor shall this clause be held to have been waived in consequence of anything to be done by the committee or any member thereof, except an express waiver in writing, and then only as to the particular things included therein. The contractors shall, if required for the valuation of extras, produce the bill of quantities with the prices thereto attached on which their tender was based." This form of clause would obviate probably some of those disputes which at present arise between architect and builder, and architect and employer, and the chief objection we entertain towards it is that no trivial alteration could take place without first obtaining the employers' consent. If employers were constantly at the works there would be no difficulty, but they are not, and it is not improbable to imagine an addition which is essential to be made, but which cannot be ordered without delay, because an authority in writing has to be obtained from a committee. Nevertheless, the advantage of an employer

knowing as the work proceeds what the cost of an alteration or addition will be, and to have the price stated beforehand, cannot be questioned.

It is equally for the builder's protection that he should obtain written instructions in every case where any additional cost is incurred, for legal decisions have made it clear that if by a contract a written order is required for extras or additional works, the want of such an order will be fatal to the contractor's claim for either, unless indeed, as in the case of "Russell v. Bandeira," he can succeed in proving that the additional work was not within the contract, or that it was *dehors* the contract. As regards the architect's authority, of course it is generally assumed that he is an agent of the employer authorised by him, and if only impliedly so authorised it is sufficient to prove the agency, as was decided in the case of "Wallis v. Robinson."

Extras and additional works are sure to arise in the performance of contracts of large amount, and the main duty of the architect ought to be to guard himself from the imputation of having caused them by neglect or omission, or of playing into the hands of the contractor. It may be said, to the honour of the profession, that many architects are anxious to clear themselves from the last charge, and that when extras arise no attempt is made to set them off against omissions rather than they should appear in their real light. The main question we have raised is, however, whether an architect should have unlimited control over deviations and extras, while the employer remains powerless. No one will for a moment hesitate to admit that an architect ought to have control over all works executed in a building, and that it would be an absurd and suicidal policy to allow an employer to order extras or variations when he so felt disposed. No contract could be carried out under such a rule, as the architect's authority would be so much interfered with; he would be constantly brought in conflict with the contractor, and in many cases the alterations would so completely alter the original plan that the contract would in effect cease to exist. Is it not desirable, however, to limit the architect's power to order alterations and extras? He may sometimes find it necessary to the advantage of the building to order additional work, or to increase, alter, or diminish the quantities or dimensions, or alter the character of the works. So far, these deviations would appear to be reasonable so long as they did not entail upon his client increased cost, and they ought to be able to be made without vitiating the contract, and subject to all the stipulations and conditions therein contained. But it often happens an architect requires something done as a variation which may entail an extra, and in this case the contract might very well give the contractor the option of reserving the question of his right to be paid till the conclusion of the work. It is not fair to leave the question an open one without an order in writing, as then the contractor may either have to pay for it, or if not he puts down a lump sum for a thing at a guess, which is saddled upon the employer.

The following clause, taken from the general conditions for building contracts as settled between the council of the R.I.B.A. and the London Builders' Society, may be quoted as a well-considered attempt to place the matter upon a fairer footing: "No extra work is to be executed except upon the express order of the architect, to be shown by any instruction or subsequent approval in writing, or by any drawing, plan, or account, signed or initialed by him. Provided always that if the architect shall require the contractors to execute any work as a variation which he may decline to order as an extra, the contractors may reserve the question of

their right to be paid for the same until the final settlement of accounts. No charge for day-work is to be allowed as such, unless the authority for the work shall expressly direct it to be done as day-work, or unless the work cannot, from its character, be reasonably valued by measurement. All vouchers for day-work to be delivered to the architect within 14 days following the week in which the work may have been executed. Any variation made in carrying out the works is not to vitiate the contract, but unless a price or schedule of prices be previously agreed on, the value of all variations is to be ascertained by measurement or otherwise. All omitted works are to be deducted at prices not exceeding those contained in the estimate on which the contract is based, and all additional works are to be valued at fair measure and value prices."

Increased security would be afforded if the contract required the production of signed instructions for any extra work, countersigned by the employer or chairman of committee, as the case may be; and it is only in the interests of architects if they would endeavour to seelaw their own independence of action can be secured without appearing to grasp a power which places their own employers at their mercy.

SUNKEN FLOORS.

SO few of the floors constructed in new houses are equal to their work, that the attention of architects and builders might be profitably called to the subject. In going over some of the newly-erected houses in the suburbs of London, it is not infrequent that one finds dwelling-house floors which have sunken so much in the centre as to destroy the comfortable assurance that they are safe. These instances occur chiefly in houses erected by speculative builders, who seem to be under no regulation of any kind in respect of floor-timbers. We have noticed serious deflection in the floors of a house rented at over £100 per annum, the consequences of which are cracked ceilings below, opening crevices between skirting and floor, and an uneven surface which makes every table shaky, and prevents large pieces of furniture like sideboards and book-cases being placed against the walls without a considerable propping underneath their front supports. Numerous books on the strength of materials have appeared, but the builder seems to regard such knowledge as merely theoretical, and is generally guided by the sizes of other timbering which he has found answer. He does not always seem to understand the well-established theorem that the strength of two pieces of timber of equal length is not always in proportion to the area of cross-section. Many practical builders have a conviction that if a timber as a joist has a larger cross-section than another it must be stronger. Thus they fancy a piece of timber 8in. by 3in., which equals 24 square inches in sectional area, cannot be so strong as a piece 5in. by 6in. which has 30in. in area. The fact is, the smaller piece is the strongest of the two if both are placed upon edge, as everyone knows who has studied the principles on which the strength of beams depends. It is easy to convince the most practical of this seemingly inexplicable fact. If two beams of like size are placed side by side, the two will resist twice the amount of one of the pieces. This is so self-evident that experiment is not needed to establish the fact; in the same way, three beams will resist three times as much as one, and so on of any number. In plain English, when lengths and depths are equal, a beam of 6in. in breadth will bear three times as much as one of 2in. in breadth. It may be shown by experiment quite as readily, that the

strength increases more rapidly with the depth. In point of fact, another law of proportion is observed—namely, that having two beams of the same breadth and length, but of different depth, the strength increases more rapidly than the depth: thus it is found a beam 9in. deep bears more than three times as much as one only 3in. deep. These are very simple statements derived from facts and experiments, and no complex conception of the resistance of certain fibres on both sides of a neutral axis, or equations in algebra are required to establish them.

In dwellings the load on a floor is chiefly made up of furniture, though this is generally placed, at least the heavier articles, round the walls of rooms. The space occupied by tables and other objects in the centre of a room reduces the available standing area, and thus, for all ordinary floors, 70lb. per superficial foot may be calculated for as the full load in extreme cases. Rules founded upon the resistance of beams to rupture are, however, of little use, as the floors may be seriously affected by deflection, and deflection is directly as the cube of the length. In regarding stiffness, the load per foot has been given by one authority as 90lb. per foot, including weight of materials; and the rule involving several dimensions is expressed in the formula

$$c^3 = i b d^3$$

from which, by inversion, the distance from centres, the length, the breadth, and the depth of beams may be found. Thus, the first of these will be generally found the most convenient in practice; which may be expressed by

$$c = \frac{i b d^3}{p}$$

in which c denotes distance apart from centres of beams, l the length of beam, both in feet, i , a coefficient for the wood used, and b and d the breadth and depth. It makes all the difference to place joists an inch nearer, though builders like to give as much interval as they can, for economy's sake. Instead of joists being placed 12in. apart, it is oftener to find them 13in., or even 14in., and the consequence is a scantling which has been found to answer in a well-built house, fails when it is introduced with a greater distance or interval. Then, the modern speculative builder's floor is seldom properly stiffened by cross-bridging; there is only one row, instead of two, or more. Of course, no practical man will deny the advantage of bridging his floor-joists; it helps wonderfully to prevent deflection under a concentrated load, for the joist immediately beneath the load is relieved of direct strain, and the joists on each side take a share of the weight. Generally, it may be taken that a properly-bridged floor is capable of sustaining, without mere deflection, twice as much load as the same floor without bridging, so that the cost of the introduction is amply repaid. It is a misfortune the Building Act does not deal with floors as it does with walls, by laying down certain scantlings for the guidance of builders, as a weak deflecting floor in course of time tends to render the house unstable, by acting injuriously upon the walls. Builders might be willing to follow regulation scantlings for their joists and rafters who could not be induced to calculate for themselves, who would scorn the idea of studying moments of resistance, or who would never be able to work out a formula.

THE WATER QUESTION.—XI.

QUANTITY RUNNING OFF THE GROUND.

THE sites of reservoirs, formed by making an earthen embankment across the stream from one hillside to the opposite one,

vary much in respect of the quantity of water capable of being impounded by embankments of the same height, and in the area of ground covered with water. The following examples are of actual sites of reservoirs, and commence with a depth of water of 20ft. at the site of the embankment, running out to nothing at the upper end of the reservoir; proceeding then with depths of 28ft., 36ft., 44ft., 52ft., and 60ft. of water at the greatest depths, with the corresponding areas of water-surface and the average depths. The height of embankment stated is the height in the middle, or at the deepest part of the bank, whether that be in the middle of the length or not. The quantity of water impounded is stated in millions cubic feet, and the area in acres.

Height of bank, 21ft.; top of bank, 4ft. above top water-level—

CAPACITY. Mill. c. ft.	AREA. Acres.	Average depth of water.
6½	16½	9.5ft.
10½	23½	10.3
15½	31½	11.4

Height of bank, 33ft.; top of bank, 5ft. above top water-level—

13½	21½	14.1ft.
21	31½	14
28½	41½	14.4

Height of bank, 41ft.; top of bank, 5ft. above top water-level—

21½	35½	18.8ft.
34½	47½	16.7
45½	55½	19.9

Height of bank, 49ft.; top of bank, 5ft. above top water-level—

22	34	21.6ft.
53	50	20.6
68½	76½	20.5

Height of bank, 57ft.; top of bank, 5ft. above top water-level—

46	44½	23.7ft.
75½	75½	23.9
95½	94½	23.9

Height of bank, 66ft.; top of bank, 6ft. above top water-level—

62½	49½	29.1ft.
105½	96½	25.1
134	110½	27.8

The capacity proper for any given situation must be determined on the basis of a certain quantity of water flowing from a known area of ground, as an acre or a thousand acres, constituting a part of the whole of the area appropriated, or from which the water to be dealt with flows; and that quantity varies with the position in which the works are to be constructed. A reservoir for the purpose of storing or regulating the flow of water off the ground may be made either in the extreme upper part of a river-basin—that is within the few thousand acres of drainage ground contiguous to the main watershed—or it may be made lower down towards the valley, wherever, indeed, the most favourable sites exist, although these will seldom, if ever, be far down the valley; for a favourable reservoir site is one in which the opposite hill-sides approach each other at a spot where an embankment may be made, and where the ground above the site of the embankment widens out, so that with a comparatively short bank a large quantity of water may be impounded.

The facts which have already been adduced of the variable quantity of flood water per acre of the drainage area, according to the position of the place of observation on a river with respect to its being in the upper or the lower portion of a river-basin, show that the cubic capacity of the reservoir per acre of its drainage area must be different in the two cases, notwithstanding that the same depth of rain may fall in either position for a short time; and the cause of difference between the two cases is that in the one the heavy rain may extend over the whole of a limited drainage area, while in the other it would extend over part of the area only. This is found to be so by observation of effects within the areas of

5,000 to 8,000 acres belonging to reservoirs in the upper parts of river-basins, for where there are two or three streams within such an area, divided by subordinate watersheds, it is frequently observed that one of the streams is much more swollen than another. The quantity resulting from a very excessive rainfall in the upper part of a river basin is 30 cubic feet per minute per acre of the drainage ground, or 500 cubic feet per second from 1,000 acres. This is equivalent to $\frac{1}{4}$ in. depth of water over the ground running off in an hour. It may fall in less time—say, in half the time—and with a continuous rainfall of the same intensity, the flow off the ground in a given time bears a greater ratio to the depth fallen in the same time, but the rainwater never runs off as fast as it falls. From the examples formerly given it may be seen that a heavy rainfall of three or four inches in as many hours, or even in less time, takes place occasionally; but it does not run off as fast as it falls, nor does it, with the same intensity, extend over any large tract of ground. Where the ground is of a porous kind, as some of the stratified formations are, it may become saturated with water during long-continued wet weather before the rainstorm begins, and yet the water does not run off so fast as it falls, for where the ground becomes saturated in this way it is comparatively flat, and the depth of water may be seen to increase where it falls, which is a proof of it; and even where the ground consists of hard, bare, and impervious rocks, and the surface is steep, the time of falling of the rain is not so long as the time of running off. We have not a sufficient number of exact observations of the comparative times of falling and running off of a given amount of rainwater on different kinds of ground and forms of surface to deduce from them any rule for each; but on the whole, and for an average kind of ground, an approximate quantity would be two-thirds of the inch depth in an hour running off in that time. An acre = 43,560 sq. ft., and 1 in. in depth of water over that area = 3,630 cubic feet, falling in the hour, and if two-thirds of that quantity run off in an hour, the rate of flow would be 40 cubic feet per minute. The question then arises how much of this during the same time will the river carry off without overflowing, after the shoals which have accumulated have been removed, benches of rock across the bed excavated, and small and unnecessary weirs taken down. The difference between these two quantities is that which has to be dealt with in the way of storage or regulation. If a river be examined and its capacity for carrying off flood-waters be ascertained in every reach, the quantity so found, deducted from that which proceeds immediately from the rainfall, would show the true quantity to be dealt with by storage or regulation in every case. The number of observations which have been adduced is small, and the information to be derived from them is sufficient only for an indication of the basis of calculation; but such as they are, they point to the probability that, approximately, the river may be reckoned upon to carry off one-half of the greatest quantity flowing off the ground, and that, of 40 cubic feet per minute per acre proceeding from a rainfall of 1 in. in an hour, 20 cubic feet per minute would pass off at once to the river, and the other 20 accumulate in the reservoir until the river-flow had begun to subside, or had subsided to any given level; but in the practical working, the flow of water would regulate itself to about 20 cubic feet per minute per acre of the drainage ground, and that rate of flow would extend over twice the length of time that the whole quantity would have done without the intervention of the reservoir, and is the quantity which the intermediate conduits must carry off to the reservoir. In viewing the position of such

works for the storage and regulation of the flow off the ground of excessive rainfalls, from any point on the line of watershed, there would be seen the track of a channel running along the hillside, following the contour of the ground, and nearly level; open in some parts and covered in others, or, according to the formation of the ground, wholly covered or wholly open. The conduit would descend, with but a slight fall, right and left from a line dividing the intercepting conduits on the hillside, to the place of storage, the distances being greater or less according to the situation, but may possibly average 1,000 yards each way from such a dividing line as that mentioned. The following sketch shows the position in a general way.

These intercepting conduits would convey the flood-waters, but not the ordinary run; otherwise the fields and small streams would be deprived of the necessary water for cattle. The conduit would pass under the streams it would cross, and the openings to admit the flood-waters would be so arranged that they would not also admit the ordinary run of water which would continue in its own course. Each such place on the line of conduit would be fenced off from the intrusion of cattle, and the occupier of the land would keep the fencing good; no other attention would be needed. Earthenware pipes would form the best conduit. If the average distance apart, down the hillsides, of these intercepting conduits, were 200 yards, and if the average distance from their upper ends to the reservoir were 1,000 yards, there would be inclosed 40 acres of ground, from which would proceed $40 \times 20 = 800$ cubic feet of water per minute. With a fall in the conduit of 1 in 200, a 2ft. pipe would carry off this quantity of water as a maximum; and if the length were divided into four portions, the diameter might be reduced successively from the lower end upwards to 20in., 15in., and 12in., or to a smaller size at the upper end. Unlike the requirements in the case of sewerage pipes, these need not be particularly well jointed. As between butt-joints and sockets, the socket joints are the better; but they need not have any jointing material. In sewerage works, the joints are too often defective in this respect, in which it is of the utmost importance that they should be perfect; but for the purpose of conveying flood-water to a reservoir it is not necessary that the joints should be watertight. The pipes should be strong, although they will not be laid at great depths below the surface: an average depth of 4ft. will be sufficient; but, nevertheless, a good strong pipe is advisable, at least, for the larger diameters. When a conduit crosses a stream of water, the arrangement would be as in the following sketch.

Through pasture fields the conduits may be open, with flat slopes which will not hinder grazing, such as 4 to 1; but the inclination, longitudinally, would be less than that of pipes, and should be limited to one which will not cause a greater velocity than

2ft. per second. Such a channel would be one having a bottom width of 3ft., and side

FIG. 2.

slopes of 4 to 1, the water at its greatest depth running 1ft. deep at the lower end, with an inclination of 1 in 1,370, and at the middle of the length of the conduit running 5in. deep with an inclination of 1 in 1,000; the depth diminishing and the inclination increasing from this point upwards towards the end.

JAMES WOODFORD, CARPENTER AND CHARTIST.*

MORE Chartist than carpenter, certainly, as far as his history as told by Mr. Henry Solly enables us to judge, must the hero of this story have been, and yet his Chartism was of such a character that no honest man or good workman need have been ashamed of it. Attached throughout his life to the moral force section, of which that admirable Cornishman, William Lovett, was the head, and opposed to the noisy party who followed the firebrand, Feargus O'Connor, till he was found out, James Woodford tells in a quiet, unostentatious way the story of a movement which has yet to be estimated at its true worth. We have had, during the past decade, some experience of the bitterness of party spirit. We know and feel, many of us, how much there is yet to be done, all in its own good time, before we may "rest and be thankful"; but we cannot fully realise what must have been the terrible state of things in England in the early days after the accession of William the Fourth.

In February, 1837, James Woodford gets his first experience of a Chartist meeting.

The King had just died—a new Parliament was being summoned—the nation was in a ferment. O'Connell, Roebuck, Wakley, Joe Hume, Leader, Col. Thompson, Sharman, Crawford, and other leaders of the Radical Party, who had stood up in the late Parliament against overwhelming odds on behalf of the rights of the people, were present, and, amidst vociferous cheering, denounced the Whig Ministry, with Lord John Russell at its head, exposed the treachery of the middle classes towards the working men, by whose aid they had got the Reform Bill, and claimed a new reform which should put an end to the wrongs and sufferings of the lower classes. Speaker after speaker eloquently denounced the existing state of things as a sham and a shame, demanding immediate redress. I was amazed beyond telling, and completely carried away by the enthusiasm of the speakers and the crowd. But there was one among them who struck me, when I first saw him on the platform, as more worth noticing than all the rest, for I felt sure he was a working man. When I found from my friends I was right, and that he was only a journeyman cabinetmaker, I looked up at him with a sort of awe and delight. For, thinks I, what a wonderful chap you must be to be sitting there with all those nobles and famous speakers, and going to speak yourself, too. I shouldn't wonder. Sure enough he did speak, and as well in one sense as the best of them; for he knew just what he wanted, and what we working men wanted, and he went at it in a plain, quiet, but very determined way, that made you feel he'd hold on like grim death, come what might, till he got all he asked for. He was a tall, good-looking young fellow, with a lot of long curly brown hair, and all the workmen round me cheered him till the roof rang again; but there were others of our class I could see didn't like him so well. And that's just what I've noticed ever since. If one working man ever gets above his mates and is cheered and clapped, there are a dozen or two thousand very soon out of temper, and run-

* James Woodford, Carpenter and Chartist. By HENRY SOLLY. In Two Vols. London: Sampson Low and Co.

ning him down—as jealous as monkeys in the Regent's Park gardens at feeding time—and all of thinking they have as good a right as he to be put up on a platform, or stuck in some important office, and be cheered and battered and clapped.

"What's the young fellow's name?" I asked; "he's a rare good 'un, whoever he be"; and then I heard a name which was pretty well known through England two or three years afterwards, though, as he was only a working man, and a pioneer in great and noble movements, who made roads for other men to pass over to victory, while he seemed only beaten at almost every point, folks don't know so much about him nowadays as about some general who has won a battle in India.

"Well, who is he?" I asked of my friend the engine-fitter.

"Who is he?" replied Mr. Rofford, rather slowly, "why, I take it that's William Lovett, the Cornish lad, and by — I wish there were five hundred like him."

Lovett, of course, became Woodford's idol, and exercised over him the salutary influence he fortunately exercised over many thousands. Woodford's comrade, David Roberts, however, who figures to some tune in the story as political delegate, orator, lover, and what-not, is less sensible, and makes much misery for himself accordingly. His love-story is a very chequered one, but comes out much better in the end than such a fellow had any right to expect, and the opinion of most readers will, we expect, be that, if Maggie Thatcher had given her sweetheart his dismissal early in the first volume, and settled down comfortably with Woodford, who loves her after his own sober fashion—that dull, matter-of-fact sort of passion, in fact, which ethereal enthusiasm, ever ready to change the object of its own raptures, sneers at, but seldom understands in all its unselfishness and true devotion.

Some idea of the view taken by working men with regard to the whole share of the blame for bad work, which many are so ready to lay at *their* door, may be gathered from the following anecdote of

Another good fellow that used to crony with us, Jem Bart, who took to me because my name also was Jem. He was but a young chap, not used to town when he first came, so I could give him a wrinkle or two. He lodged with us at Mrs. Taylor's, and when I first knew him he hadn't been regularly apprenticed, and was what is called an "impr'ver" at a large cabinet-maker's shop in the West-end. Well, one Saturday night he comes home regular down in the month—had got discharged, and no mistake. "What is it for, Jem?" says I. So then he told me how he had always tried to do his best, but the foreman said he was a deal too slow; they wanted work turned out sharp and quick, and "he didn't ought to spend such a lot of time over it." "And at last he said I'd better go and try to get a situation in some amateur gentleman's workshop, where they only did fancy work, and where there were no customers. So," says Jem, "I'm blowed if ever I'll take pains with my work again, 'cept to get it out of hand and done with." "Ay, but," I replied, "there are other firms in the West-end besides ————, and at some of them you will find good work is cared for more than fast work, if I've not rightly." Next week he went round to them all, but trade was slack, and there were more men being turned off than taken on; and, as he had never joined a Trades' Society before he was discharged, he had no box to come upon, and the poor fellow was very hard up. We made a little box for him; but, of course, that didn't last long.

By and by, Woodford, in the course of his work, finds his way down to Eastleigh, in Southamptonshire, where he converts a young person to Chartism, and ultimately gets sentenced himself to two years' imprisonment on a false charge of poaching and assaulting gamekeepers. From this unjust punishment, however, he is released by the confession of a criminal. His subsequent married life is a good deal of a failure, and must be traced by the reader himself. Davy Roberts, who acts as a sort of chorus to the end of the chapter, finishes his career as a failure, and is left a failure. The story is a good deal of a failure, and is a failure in many respects. They are both becoming better

off in every way than during any previous portion of their lives. Woodford himself ends his story with the following sensible reflections:—

I have now become an employer in a pretty large business, but I haven't forgot the days when I was a journeyman, and I believe I've tried to do what little I could as an employer to help journeymen and apprentices according to what I should have liked masters and foremen to have done for me. You may sometimes see journeymen, when they become employers, as I think I said somewhere before, act the tyrant worse than any who have always been what's called gentlemen. But then, again, I've seen workmen turn against an employer who has done all he possibly could for them (sometimes doing it at his own cost), and treat him shamefully. There are faults to be mended on both sides, and sometimes I think we want a whipping all round. But, then, there's a deal to be done, also, it strikes me, as to mending the political machine. Looking back, and after thinking of our Chartist days, I can see, or fancy I see, how politics have got to do with most of our troubles, apart from moral or religious matters; and that's why, among other lesser reasons, I've written what my friend has made into this tale. Noble-hearted Lovett has been taken to his rest since I began writing about him. His faithful and worthy ally, Bembridge, sleeps in Kensal-green cemetery, after having helped more than one clergyman to see that they must try to establish the kingdom of God on earth, and not merely prepare men for it, as they say, in heaven. Many other of Lovett's best supporters have also passed away; and I wanted English workmen to let me help them to remember some of the lessons which the labours and suffering, failures and successes of all these true patriots should teach us.

Brother working men, let me ask you, as the last word I shall write, to beware of selfish, unscrupulous leaders, and their thick-and-thin supporters. Many years' experience have told me (though, as I have not much book learning, I may be wrong) that nothing keeps the world back so much as jealousy and back-biting among leading men and their partisans. I don't think the devil does half so much harm by his straight-going sinners, as by his sneaking, backbiting, jealous saints. There are always plenty of good folks trying to remedy wrongs; and they would soon do it if they didn't quarrel, and envy, and hate one another as they seem to do. It is all these dirty tricks which strike down the good men and true, who ought to be leading the way, and give unworthy men power to do mischief and hinder good. I saw it said somewhere, once, that "half the time of the wise is spent in correcting the errors of the good," which may be very true, and shows how careful politicians, philanthropists, clergymen, and everybody else ought to be, not only to desire to be of use, but to learn the best way of being so. But I'm quite sure half the strength of both wise and good is lost in resisting the egotism, ambition, and envy of those who get the credit of being honest and able, when they're neither.

So that's the moral I learnt from the Chartist movement as it went on forty years ago in this old England of ours. And I hope and pray my hard-headed, and warm-hearted, and often long-headed brothers of the journeyman class won't let the labours, and sufferings, and failures of the great true-hearted chiefs of that movement, nor the errors and sins of those who ruined it, be altogether forgotten. Heaven help us all, say I, to know and to follow those only who are worthy to be our leaders, and Him most of all who, by self-sacrifice, showed us what a leader should be.

THE ASSOCIATION OF MUNICIPAL AND SANITARY ENGINEERS AND SURVEYORS.

THE annual meeting of this association was held—as briefly reported last week—at Birmingham, on Thursday, Friday, and Saturday, last week. The Past-president (Mr. A. W. Morant, of Leeds) temporarily occupied the chair at the opening of the proceedings.

Mr. THOMAS COLE (secretary) read the annual report, which stated that 25 new members had joined the association this year, three members had died, and the total membership now numbered 1204. The report urged the members to make every effort to increase the roll of the association. The report was adopted, and Mr. Morant, in vacating the chair, introduced his successor, Mr. W. S. TILL, the president-elect for the ensuing year.

PRESIDENTIAL ADDRESS.

Mr. TILL then delivered his presidential address, in which he expressed a hope that

during this the third visit of the association to the borough some useful information might be gained by the members, and that the objects of the association—viz., the dissemination amongst the members of that knowledge and practice which fell within the department of an engineer or surveyor engaged in the discharge of his duties under the local and public Acts of Parliament—might be attained. It had, therefore, occurred to him that a brief description of the borough, together with information as to its streets, night-soil and sewage works, would be the most interesting subjects for him to address the meeting upon. The borough of Birmingham had an area of 8,420 acres. Its lowest point, which was at Sillley, where the sewage-works were situated, was 290 feet; and its highest, which was on the Hagley Road, was 610 feet above mean sea level. The population in 1861 was 296,076; in 1871, 342,505; and in 1881, 402,296; whilst the rateable value at the present time was £1,528,000. The area unbuild on was about 2,400 acres, so that the population per acre was 66. In the borough there were 187 miles of highways repairable by the Council, and with the exception of some fifteen miles which were paved with wood and granite, the whole of the carriageways were macadamised. There were in addition about ten miles in length of private roads. The average cost per square yard per annum of cleansing, watering, and macadamising the carriageways for 1880 was 5d.; the maximum cost of any one street for that year was 4s. 3-35d.; whilst the first cost of making was about 2s. 3d. per square yard. Woodpavement was first laid by the Improved Wood Pavement Company in Moor-street, in 1873. There were about 30,000 square yards of wood pavement in the borough; that in Bull-street was laid in 1874, and this had not yet been interfered with, but now required relaying. The company were paid 14s. per yard for this, as well as several other lengths; they maintained the same free of charge for one year and for fifteen years thereafter for the sum of 9d. per square yard per annum; the maintenance money being payable at the expiration of the sixth, eleventh, and sixteenth year on the surveyor's certificates that the works were in good condition. The first lengths of granite pavement now in existence were laid in Broad-street and Lawley-street in 1862. The Council in 1872, with the view of reducing difficulties connected with the treatment of the sewage at Sillley, decided upon the introduction of the pail system for collecting night-soil, and at the end of last year there were about 32,000 pails in the borough, estimated to supply about 250,000 persons. There were about 1,000 water-closets, and the remainder of the population was supplied with the old form of combined privy and ashpit. The contents of the pails and ash-tubs used in connection therewith were collected weekly, and conveyed to wharfs within the borough situated at Rotten Park-street, Shadwell-street, and Montague-street. The contents of the old privies were removed as often as required, and sold after being roughly sorted, whilst the contents of ash-tubs were screened, mixed with the faecal matter, and sold as manure. At Shadwell-street Wharf, some four or five years ago, the Council erected one each of Fryer's four-celled destructors and carbonisers, and also two of his concretors; the two former performed their work in a satisfactory manner—the destructor reducing six boat-loads of rubbish, or about 150 tons, to 25 tons, and the carboniser turning out a very fair charcoal; but owing to continual complaints by the General Hospital authorities, whose hospital was only separated from the wharf by the canal, the use of the whole of these had to be abandoned, and the mixing of screened ashes and excreta was now only carried on there. The number of pails delivered at Montague-street wharf was about 17,000 per week; the contents thereof were estimated to weigh about 160 tons, whilst the average quantity of ashes collected weekly from the premises where these pails were in use averaged 505 tons per week. The cost of the night-soil department in 1880 was £12,096 17s. 5d., of which £27,196 2s. 2d. was for collection, &c., of pail contents, and the remainder for the removal of old night-soil; the receipts for pail contents were £5,702 3s. 1d., and for old night-soil £1,992 8s. 7d., or a total net cost to the borough of £35,296 5s. 9d. The systematic drainage of the borough of Birmingham was commenced in 1852 by the construction of the Hockley Brook and the River Rea main

intercepting sewers, under the superintendence of Mr. Pigott Smith. The total length of sewers now under the care of the Council was about 175½ miles. The history of the treatment and disposal of the sewage had until recently been one of difficulty and opposition. In consequence of proceedings instituted by Sir C. B. Adderley, the Public Works Committee, which had then the matter in hand, presented a report to the Council in June, 1871, recommending the acquisition of from 2,000 to 2,500 acres of land down the Tame Valley; but this being considered too costly the Corporation, on the recommendation of the Sewerage Committee, which was specially appointed for the purpose, promoted a Bill in Parliament in 1872 for the purchase of 800 acres of the same land near Kingsbury, about eight miles below the present outlet. This bill, after a lengthened opposition in Committee was thrown out on the third reading in the Commons, owing to the opposition of the landowners in the neighbourhood. To satisfy the requirements of the Court of Chancery the lime process was at once adopted and more land was obtained at Saltley, and four additional sets of subsidiary tanks were constructed, to which another large tank had recently been added. The order of sequestration was discharged in 1875, and in 1877 the United Drainage Board was formed. On this Board now devolved the duty of treating and purifying the sewage delivered by the various constituent authorities at the outlet works. To meet the additional strain thus brought on the works the Board last year entered into negotiations for the acquisition of 867 acres of land in the neighbourhood of Castle Bromwich, to be used for irrigation with the effluent from the tanks. The Board was met in a friendly spirit by the landowners, and terms satisfactorily arranged. A Local Government Board inquiry was held in April of this year for power to borrow £188,000, for purchase of land and works, and the requisite permission was recently obtained. The area of the present Saltley Farm is 272 acres, of which 170 acres is freehold. The subsoil is generally of a gravelly nature, with a little clay in places. The three large tanks and sixteen smaller ones have a combined capacity of 43,310 cubic yards, or about 7,300,000 gallons. The amount of sludge deposited in the tanks during 1880 was 178,400 cubic yards, or about 490 cubic yards per day, and required an area of 53½ acres of land for digging-in the same, or rather more than one acre per week. The average dry-weather flow of sewage was about 13 million gallons per day, the population actually contributing that amount being roughly estimated at 450,000, being about 29 gallons per head. A little over 13 tons of lime were used per day, the lime being slaked and ground with water under edge runners. The sludge was lifted from the tanks, run into beds about 8 yards square to a depth of about 18 inches, and allowed to drain for a week or two: it was then dug into the land and covered with the soil. The thorough drainage of the land greatly facilitated the operation of dealing with the sludge. The sludged land was very favourable to the growth of cabbage, kohlrabi, and mangold—as much as 60 tons of the latter being obtained per acre. No nuisance arose from the present method of dealing with the sludge, as was sufficiently proved by the fact that there were nearly 3,000 houses within half a mile of the farm boundary, no complaints being made by the inhabitants thereof as to the operations now carried on. The cost of dealing with the sludge during 1880 (*i.e.* lime, labour, repairs, rent, taxes, &c., but exclusive of interest and sinking fund on capital) was £12,356, or about 1s. 4½d. per cubic yard of sludge intercepted. The new farm at Saltley was not yet laid out, but it was intended to connect it with the Saltley Farm by a conduit about 2½ miles long and 8 feet internal diameter. It was proposed to lay it out for broad irrigation, except about 40 acres intended as an intermittent filter-bed for use in cases of emergency. About 648 acres would be freehold, and the remainder leased for long periods. Mr. Till concluded by expressing his willingness to do all he could in behalf of the objects of the association.

Mr. Pritchard moved a vote of thanks to the past president, which was seconded by Mr. Lynde, and carried.—On the motion of Mr. Morant, seconded by Mr. Ashmead, a vote of thanks was accorded to Mr. Till for his address.—Several suggested amendments of the rules were considered, and it was resolved that mem-

bership should be limited to the chief officers of Corporations and sanitary authorities, and that members who, after 1881, cease to hold any public appointment shall be eligible for re-election, but disqualified from holding any office under the association.

Later on the members proceeded in omnibuses to inspect the sewage farm at Saltley. There they were met by Alderman Avery (chairman of the Birmingham Tame, Rea, and District Drainage Board), who conducted the party over the works, and explained in detail the nature of the various operations. After luncheon, the members visited the Montague-street wharf.

DINNER.

In the evening the members dined together at the Queen's Hotel. The president of the association was in the chair. After the introductory toasts, the Vice-Chairman (Mr. Lewis Angell), in proposing the "Municipal Institutions of the Country," referred to a previous meeting of the association held in Birmingham, and said that that meeting was one of the most successful they had had. He remembered that on that occasion the chair was taken by a Mayor of Birmingham, who had since become President of the Board of Trade. They were extremely gratified with the reception the association had met with on the present occasion. At Saltley they had been received by Alderman Avery, and at Montague Street by Councillor R. F. Martineau, both of whom manifested such an intimate knowledge of the operations they so kindly undertook to explain, that it might very well have been concluded they were engineers scientifically describing their own works. Nothing could have been more clearly and lucidly explained in every possible detail. It was well known that Birmingham was a place in which the inhabitants took an intense interest in their municipal affairs, and that being so, one could hardly be surprised at the success which had been achieved.—Councillor R. F. Martineau, in responding, said that the Birmingham Corporation, partly benefitting by the success and great deal more by the failures in other places, had got upon what they believed to be the right lines. Upon these they intended to continue, and see whether it might not be in their power, by perfecting the details of their system, to make their mark on the history of this great question, and possibly to aid others in removing one of those great difficulties in which our civilisation had placed us. Councillor Sam. Edwards proposed "Success to the Association." He referred to the inexcusable indifference of so many of the middle classes to the great question of sanitation, and expressed a hope that, through the work of such an association as this one, by the holding of conferences, the dissemination of right and left of useful knowledge, and the establishment in great cities of health classes—the time was rapidly approaching when an intelligent public opinion would be formed, and what was of still more importance, would be carried out. At present many wealthy people seemed anxious only to build large and showy houses, and furnish them luxuriously, without paying any attention to those sanitary arrangements which, after all, were of such vital importance. By the exertions of inspectors of nuisances and other municipal officers the humbler people were well looked after, and he really thought that those who required attention now were those who thought they knew so much, but proved by their practice that they knew so little. Mr. C. Jones (general hon. sec.), in responding, spoke of the advantages of the association both to the members and the public generally.—The other toasts were "The Visitors" and "The Officers of the Association."

THE BIRMINGHAM CORPORATION SEWAGE WORKS.

The proceedings were continued on Friday, in the Council Chamber, under the presidency of Mr. W. S. Till.—In the morning a discussion took place upon the Birmingham Corporation works visited the previous day.—Mr. J. Lemon (Southampton) protested against the continuance of the intercepting works at Montague Street, which he described as one of the most disgraceful exhibitions of sanitary work he had seen. He hoped the Corporation would see their present folly, and at no distant date altogether remove the Montague-street abomination. The system of sewers existing in the town was fully capable of removing by water-carriage the whole of the

excreta of the borough with more efficiency and less nuisance. The present system was likely to spread disease, and was, therefore, revolting to every sanitarian. He was at a loss to know why the Corporation carried it on, and he felt it his duty to call upon the members to speak, openly and fearlessly against one of the most abominable systems in this country. Mr. Gledhill (Hockliffe) said that, with regard to the disinfecting of the material collected, he should be very sorry to recommend his Board to follow the example of Birmingham.—Mr. E. B. E. Clark (Hove) also spoke in condemnation of the system in Birmingham, while admitting that it obtained its greatest possible advantages in this town. In Liverpool and other large towns the water carriage system was carried out in its entirety. This was proof that the system could be used by poorer classes anywhere. It was difficult to understand why the pan system was continued.—Mr. J. Lobley (Hanley) made some remarks on the same subject, and was followed by Mr. C. Jones (general honorary secretary), who said he also must protest against the association, directly or indirectly, sanctioning the interception or pan system they had seen in operation in Birmingham. He regarded the system as crude, rude, and absolutely bad.—Mr. G. Jennings (Rotherham) said he believed the water-closet system, properly carried out, was by far the cheapest and the best in the end.—Mr. Lewis Angell, one of the past presidents of the association, said the Birmingham plan of interception was filthy, dirty, degrading, and demoralising in every possible way. It was opposed to all decency; it necessitated a disgusting occupation for a number of persons, and afforded means for the dissemination of disease. He believed the members of the association would be wanting in their duties as engineers if they did not give expression to the views they held on the subject. He believed the water-carriage system would prevail in the end.—Mr. E. Pritchard (district hon. sec.) said he did not approve of the system of interception and removal.—Mr. Lynde (Manchester) also condemned the pan system, and spoke in favour of the water-carriage system.—Mr. Gordon (Leicester) said the operations at Montague-street were, at all events, carried on without any apparent nuisance to the neighbourhood.—Councillor R. F. Martineau, at the request of the Chairman, offered some observations in the way of reply to the criticisms of the previous speakers. The chief objections to the pan system, he said, appeared to have been summed up in the words, "dirty, disgusting, and demoralising." He understood that that was a pretty accurate account of the general feeling of the meeting. He hoped that those effects had not extended to the committee which had had the management—but he did not know to what other class of people they might be considered to extend. The members of the association must recollect the circumstances of Birmingham under which the pan system was adopted. He thought that as engineers they would appreciate the enormous cost which would have been necessary in obtaining sufficient land to treat properly the whole of the sewage, if there had been no other system than water-carriage. Compared with the old ashpit, which it superseded, the pan system was certainly not to be condemned as dirty. The most careful precautions were taken to ensure cleanliness and prevent effluvia. He had had no experience of the water-closet system as applied to large towns, but thought that it would be exceedingly difficult, if not almost impossible, in the poorer quarters of towns to keep them in such order as to prevent smells arising from them. Even in the best-regulated households they often became a great nuisance.—At the close of the discussion a vote of thanks was accorded to Alderman Avery and the members of the committee for their kindness and courtesy to the association.

THE SANITARY SUPERVISION OF DWELLINGS.

Mr. Lewis Angell read a paper on "The Sanitary Supervision of Dwellings," in which he submitted the following propositions:—That a more efficient and extended supervision of the sanitary and constructive details of all dwellings is necessary; that such supervision should be conducted by the responsible officers of the local sanitary authority, and not left to private commercial enterprise; that it is just and expedient that fees be imposed on all new buildings to provide the cost of such supervision. In con-

clusion, he expressed greater hope in education than in officialism. If sanitary science were taught in our schools, if organic germs received some of the attention devoted to the Greek particle, if our youth were taught to avoid vitiated air as they would false quantities, if elementary hygiene were recognised as of equal importance with simple equations, many a good and useful life would have been saved for the commonwealth. But now, in the selection of a house, more attention was given to a dado or a cornice than to the cistern or sink. The canon laws of house-sanitation were very simple and easy to observe. There should be no connection between the house and the sewers excepting for sewage; the soil-pipe should not by any chance ventilate itself into the house; all other drains or pipes from cisterns, baths, lavatories, sinks, &c., should discharge into the open air; the drinking-water should have no connection with the closet. These were cardinal rules, the neglect of which nearly everyone could discover for himself. There were of course other matters, some of which were more difficult to detect. Sanitarians were few and the population was large; the population was also careless, and it was not until an unexpected, cruel, and irreparable death had smitten a family with deep affliction that conviction was forced upon the survivors, and alas! when too late, they recognised preventable causes, and adopted the simple precautions and protections which at present were almost exclusively the privilege of the occupants of walled houses and guilds.

In the discussion which followed, Mr. E. B. Elliot-Clark said that great difficulties had to be encountered before an effectual supervision could be exercised throughout the country. Supervision, if it was to be effectual, must be exact and impartial. If coercive laws were to be carried out, no discretionary powers should be left in the hands of local authorities or officials. —Mr. J. G. Lynde (Manchester) said that a system of supervision embracing most of the points recommended by Mr. Angell had been in force for several years at Manchester. A certificate was given by the city surveyor to the effect that the by-laws had been complied with before a house could be occupied. This was done without any cost to the builders, and he thought the system of fees objectionable. —Mr. Ashmead (Bristol) said that supervision had been exercised in the town he represented for many years, and a special charge was made to builders for the certificates that the conditions had been complied with. —In the course of further discussion, the President said that, practically, there were no by-laws in operation in Birmingham until 1876, when a building surveyor was appointed. With reference to receiving fees, he did not like the idea of receiving them; still it was a matter of impossibility to prevent the receipt of fees. With regard to the charge for street buildings, they charged 5 per cent. for extra expenses of supervision. —Mr. Angell having replied to the discussion, a vote of thanks was passed to him.

RIVERS CONSERVANCY.

Mr. R. Vawser (Manchester) then read a paper on "Rivers Conservancy." He said that the Bill for the improvement of rivers and the prevention of floods, which had passed the House of Lords, contemplated extensive engineering works for ameliorating the condition of flooded districts. It provided that any Sanitary or Conservancy Authority having jurisdiction within any part of a river basin, or contiguous thereto, could initiate proceedings for the establishment of a Conservancy Board for their district, and that different classes of property should contribute towards the expense in different proportions; the lowland, which it might be presumed would derive the greatest benefit, being taxed at the highest rate. The powers of the Board would include the cleansing, repair, and maintenance of all existing watercourses or outfalls for water and others improvements. After further reviewing the Bill, the speaker said he believed that the powers proposed to be given to the Local Government Board to group the various authorities, and to fix the boundaries of the conservancy districts, would prevent an injustice where a district free from floods was sought to be taxed for the benefit of the surrounding districts. The proportion of expense which the lowlands, middlelands, and uplands would have to bear was a fair subject for discussion. The Bill provided

that the highest rate payable in the uplands should not exceed one tenth of the rate payable by the district which paid the highest general rate. He believed that the provision limiting the liability of the uplands to a small share of the expense was a wise and fair arrangement. The Bill was a general one to set up machinery by which provision might be made for the interests of each separate river basin or locality, and such would not necessarily be applied in its entirety to parts of the country or conditions for which it is entirely unsuited. The Bill provided that an urban authority in districts with a population of not less than 25,000 might be constituted a conservancy board within its own district; but he believed that that provision could not be extensively adopted without loss of efficiency. The anxiety of some districts to be exempted from the operation of the Act was difficult to understand, because it could not be applied in any district until put in force by provisional order, and it was quite competent for any person to oppose such order, and if good cause could be shown why the Act should not be adopted it would not be put in force. The works of any authority for sewage or waterworks purposes were specially protected by the Bill. He invited the members of the association to an expression of opinion on the Bill, in the hope that it might contribute to the chance of the Bill becoming law during the present session, as he believed the Bill was drawn with a due regard to all existing and vested interests, and contained all the essential elements of a most useful measure, and as such deserved the earnest support of sanitary authorities. —Mr. Parry contended that the application of the Bill would be useful in the case of an urban authority. —Mr. Mackie (Glasgow) considered that the Bill would be of great advantage, and hoped it would become law. —Mr. Clark considered that if they were to have conservancy boards with the various other boards that were in existence, matters would become very complicated. He thought it would be better for the Legislature to wait until they dealt with the whole question of county government, and considered that county boards would better deal with the subject. —Mr. Lemon (Southampton) differed with the previous speaker as to the matter being in the hands of county boards. In some cases floods were caused by the boundaries between the counties, and he did not see how county boards were going to exercise their powers in such cases without amalgamating. A conservancy board would be useful, because it would provide for a number of districts acting in common for the general good. —The President said he could give an illustration of the necessity of a conservancy board. The borough of Birmingham was bounded on one side by Aston Brook, which separated it from the populous suburb of Aston. The owners of property had, wherever they could, built into the watercourse, and left very little room for the flow of water. Through the deposition of brick ends and rubbish, the bed of the stream had been raised three or four feet above its natural level, and the Local Board of Aston and the Corporation agreed to cleanse the stream and deepen the bed. They applied to the Local Government Board for power to borrow the money, and the reply was that they had no power to do it. He had therefore to go before the county magistrates to get their order, and the sum of £22,000 or £23,000 had been expended in widening and deepening the brook. There was now some difficulty for the Aston Board to pay the excess of cost. Another stream running alongside the borough and through an urban portion of the borough was the River Rea, which also required cleansing. There was to be a meeting of the three outside parties next week, to see if terms could be arranged to do the work. Some body like that which the Rivers' Conservancy Bill provided for would furnish the necessary means for doing the work. A vote of thanks was then passed to the reader of the paper.

PRACTICAL NOTES ON PLUMBING.—V.

By P. J. DAVIES, H.M.A.S.P., &c.

BRANCH JOINTS (PREPARING).

THESE joints are made the same as the finished joints, Fig. 21. Proceed as follows:—For small pipes take a half-inch gimlet,

* All rights reserved.

and bore a hole (taking care not to let the gimlet enter the lead on the back part of the pipe or joint) in the pipe at the point where the joint is

required, as at E, Fig. 22. For larger pipes, see "Soil-pipe Branches."

BOLT, OR TOMMY.

The bolt, or as it is sometimes called the "Tommy," is shown in Fig. 23. Insert the

point A in such a manner that you can with the hammer knock the lead up so as to raise it, as shown at the sections, Figs. 24, 25, 26, and 27.

This is worked by striking the bolt at B or D in an upward direction. The object for raising this part of the leaden pipe is to prevent the spigot, or male end of the pipe, interrupting the passage of water way through the pipe. Having the pipe worked up to the right shape or size—see Fig. 28, prepare the male end by rasping it off as shown. Next soil and shave it, but do not shave this male end too high, as the joint will not look well. The male end should not be shaved more than an inch from D to E.

Fig. 24 shows the female part prepared and shaved; the side shaving line D E F is shown at Fig. 21, and care should be taken to shave it truly, and to this shape, low enough also to get

a good body of metal at the side G, as you will be sure to get plenty at J Q. The side of this joint, when finished, should look like that shown at G, Fig. 26, which in a great measure owes its shape to proper shaving.

Fig. 25 represents the branch-joint in section, showing that the male end should not be dropped below the water-way of the main-pipe, for, so sure as it is, it will always be a nuisance as regards noise, to say nothing of checking the flow.

Careful examination of this diagram will show you the thickness of the solder at the solder line R E, a point where nine-tenths of the plumbers cause a thorough waste of the solder by bringing this line straight, instead of curving it as at the line P J D. Notice in this diagram, at Q, that the lead is turned up square; it should be rapped off as at B. Caution: When hammering up the sides of branch joints with the bolt, be careful not to injure the sides or bottom with the bit, or to leave a burr turned bottomwards into the pipe at K L.

SLOPE BRANCH JOINTS FOR WASTES, &c.

According to theory all branch joints should be fixed so that there will be an easy sweep for the water, and, indeed, it should be when possible, always put into practice; but circumstances will not always allow this. All wastes and branches of soil-pipes should enter in this manner.

Fig. 27 shows this kind of branch joint, which is prepared as follows:—Work the hole to the shape of the above figure, *i.e.*, much longer than you did for the square branch, then take your male pipe and offer it into its place, and to as near the angle as you can; whilst in its place scribe it to this shape (lines will be given for the setting out of this work when we come to soil-pipe work and fixing); take it out and rasp it off as at E, Fig. 27, then soil and

shave it, as also shown in this Fig. Take care that you shave the under part P D far enough back; otherwise you will be pinched for room

when wiping, and the joint will look ill-made, and probably the solder will be parted, especially if worked a little cold.

SOIL-PIPE BRANCHES.

In cutting the pipe for large branch-pipe work, such as 3in. or say 4in soil-pipe, the lead should be differently cut, whether for slope or square branches. It is best done as follows: First determine the length of the branch as from D to E (Fig. 22), by placing the end of your prepared male part on E D, or by lines struck to the angle and size of the pipe. Having the length, take a small red-hot iron (but here put a piece of paper inside your pipe to catch the hot lead) and burn the two holes E D and the slot C F to about this shape, leaving a little at point E D just to turn up and look like that at K (Fig. 27), and also like that at D E (Fig. 29). Next rasp off the corners B C F I; then just warm the lead about the hole, with shavings, &c., and take your bolt or dummy (dummy is a piece of cane having a lump of lead run round one end, with plenty of rosin to keep it firm; the rosin should be run in when the dummy is cast on, or a short piece of 1/2in. iron pipe is very handy, in which case you must tin the iron—a system that will be explained in a future chapter), and work up the sides to the shape of Fig. 24, or if on the slope, to the shape of B D E, Fig. 29.

(To be continued).

THE SCIENCE AND ART OF SANITARY PLUMBING.—V.

WATER-CLOSETS AND SOIL-PIPES.

THE last but one of the series of lectures on plumbing to plumbers was given by Mr. S. Stevens Hellyer at the rooms of the Society of Arts on Wednesday night; Mr. J. Rogers Field, B.A., C.E., occupied the chair. In his opening remarks, the lecturer said that as joints, joint-making, and traps had occupied so much time, he proposed to deviate somewhat from the original programme, and should confine attention that evening to the consideration of water-closets and soil-pipes, and in his next, the final lecture, to house-drainage and ventilation, entirely dropping the subject, "The Art of Lead Laying." Having quoted from "The London Art of Building," published in 1743, a schedule of the prices then current for plumbers' work, which were considerably higher than at present, the lecturer traced the history of the water-closet. According to the records of the Patent-office, no patent was taken out for a water-closet till 1775 by Alexander Cumming, although special licenses for protecting inventions had been granted since 1617. Although, therefore, the presumption was that no w.c. other than of a simple nature was in use up till 1775, this first specification clearly established the fact that water-closets were in use, that soil-pipes were well known, and that these w.c.'s were fixed "upstairs"—*i.e.*, in various parts of the house. Another patent was taken out in 1777 by Lemuel Prosser, also a London plumber, for an improved w.c., which seemed in construction to be about as bad as a pan-closet. About six months after this, in 1778, Joseph Bramah, of Cross-court, Carnaby Market, Middlesex, cabinet maker, took out a patent for his invention of the now well-known valve closet. The great advantage of Bramah's closet over Cumming's was that the former was made with a valve which seated itself against the bottom of the basin by a cranking arrangement, whereas the latter slid under the bottom of basin. From Bramah's specification it was clear that traps were used in his day and that they were offensive; that soil-pipes were fixed without ventilation, and that such pipes emptied themselves

into drains, and the drains into cesspools. Mr. P. J. Davies, in a letter to the BUILDING NEWS, had said that Bramah "knocked the siphon trap on the head," but if they turned to the diagram, enlarged from his specification, the audience would see that Bramah himself used a siphon-trap on the overflow-pipe of his w.c.

With regard to siphon-traps stopping up, as alleged by Mr. Davies, it could only be from bad flushing. Mr. DAVIES at this stage of the lecture, rose from the body of the meeting and explained his meaning, frequently interrupted by and as often interrupting Mr. Hellyer, until the Chairman ruled that no discussion could take place during the lecture. Upon this, a second plumber rose in another part of the hall, and asked how plumbers were to answer Mr. Hellyer. A previous chairman (Dr. Corfield), in checking discussion, had said that plumbers could point out any errors they thought he made in the professional papers, and now Mr. Hellyer answered those letters in the room. Mr. Hellyer with some warmth said that whatever Mr. Davies might write in the BUILDING NEWS he should not reply therein; Mr. Davies was not worth smoke. In lecturing there he was not responsible to the BUILDING NEWS, but only to the National Health Society, and he should not write to that paper. After some further controversy, Mr. Hellyer promised to allow Mr. Davies ten minutes at the close of the meeting to reply to any remarks he might have made about his views. Continuing his lecture, Mr. Hellyer said although Bramah by his invention tried to shut offensive smells out of closets, many inventors and manufacturers had since tried and still tried with success to make closets which had large "containers" for generating and holding bad smells. Bramah's closet had been since improved in many ways. The basin-valve had now an india-rubber seating, instead of one of metal, and the water-box was now made of iron instead of lead; but Bramah's aim was to "shut out bad smells," whereas men are to-day looking for closets to be self-cleansing and for the drainage to be wholesome. The difficulty of getting the slider of the one closet and the crank metal-valve of the other always to seat themselves, and of getting them to stand rough usage, led to the invention of the pan-closet, which was improved by William Law, of Soho, in 1796, and further modified in 1826 by William Downie, senr., of Exeter, who reduced the size of the container. Some reasons for the large sale and extensive use of the pan-closet were, the lecturer thought, that there were no valves to get out of order, and it would stand rough treatment well. But it was the most unsanitary water-closet, and ought never to be used. At his (the lecturer's) factory they were making some at that very moment, for people would have them, but he never allowed one to be made if he could help it. No matter what the material of the container might be, the pan could never be a wholesome closet, on account of the corroded excrementitious matter which adhered to it. The surface exposed to foul deposits was about 5ft. super., against the 9in. or 10in. of a valve closet; and whereas the latter could be easily washed out, the former could not be effectually cleansed. In selecting self-cleansing water-closets, great care should be taken. No water-closet should be fixed which would not allow a flush of water to cleanse any part of it which could become fouled by usage. He would not in that lecture refer to any man's work in closet, nor to his own, but would simply lay down the rule that no w.c. should be fixed which would not allow of being thoroughly cleansed and its trap washed out every time it was used. The second subject, soil-pipes, he would divide into five heads, *viz.*:—(1) Materials: their sanitariness and durability; (2) sizes; (3) position—outside or inside; (4) disconnection from drains and ventilation; and (5) traps for securing lead soil-pipes in position. Firstly, then, of what material should soil-pipes be made? Looking at the question from a higher platform than trade interest, he would answer lead, especially for this climate. Although stoneware or earthenware pipes might be more durable, the soundness of the joints could not be relied upon an hour, the connections with the w.c. branches and the w.c.'s would be difficult, and the sockets would form ledges for the filth to accumulate upon. The only material that came into competition with lead for soil and waste pipes was cast-iron, but lead was more durable, more compact, and more wholesome. Iron was a

material which, used in pipes, deteriorated from without and within under the corrosion and rust, whereas lead was practically only acted upon on the inner side, and that to a far less extent than cast iron. If constantly painted, cast iron might stand; but this involved constant expense and care, and any failure to fully protect the back of pipe would involve danger, added to which, rust might go on beneath the surface of paint. Except in urinal wastes, the accumulation of filth upon leadwork was very slight as compared with iron. The latter material had certainly one great advantage, that the carpenter could not drive his chisel or nail into such a pipe, and so endanger the health of the inmates, and further, the action of hot-water on thin lead-pipes was very injurious, except where slip-joints were used, and these were of course inadmissible in soil-pipes. As to the second head, the size, it would be remembered that 15 or 20 years ago it was common for plumbers to fix, under the direction of specifications, 6in. soil-pipes to take the branches of four or five w.c.'s, and with many architects and builders, as well as plumbers of to-day, 5in. and 4in. were the general sizes, and that too for only one water-closet. The smaller the size of the soil-pipe the more efficiently was it flushed each time the closet was used, and there was no reason why it should be so much larger than the outlet of the w.c. into it. In private houses he considered a 3½ in. lead soil-pipe quite large enough to take a tier of three water-closets—supposing the soil-pipe to be ventilated at top and bottom, and each trap to be ventilated as well. A 4in. soil-pipe, when of lead, and made by hydraulic pressure, was large enough to take the branches from several more w.c.'s, and a 4½ in. soil-pipe was ample to take a tier of six double closets. The author had had 3½ in. lead soil-pipes fixed to take tiers of three w.c.'s, and had never known the smallest inconvenience therefrom; indeed, they were cleaner to-day than 4in. pipes fixed close to them. The third point was the position of soil-pipes—outside or inside. He gave his voice in favour of outside, and in all new houses he would insist on their being placed externally. There was no danger from frost if no water was allowed to stand in the pipes, but if water leaked into pipes from a closet valve during the winter it would, of course, become clogged up. The discharging ends of the pipes should be carried below the ground-level out of the reach of cold sweeping winds, and it was unwise to take rain-water into soil-pipes, for the sun would often melt the snow at the top, but the trickling water would freeze again below. If there was a good supply to the w.c. and if it was well looked after, there was not the smallest fear of freezing up in this country. The action of the sun on outside lead-pipes was often injurious, stretching the material between the tacks, bending it out of shape, and weakening it. Where no slip joints could be introduced, lead pipes should be kept in an angle, or in some other way out of the direct rays of the sun. Another reason for this was that when the pipes heated, the excrement might partially dry upon the pipes, especially where the w.c.'s were used with but little water. This point told also to a certain extent against internal soil-pipes. The risk of getting soil-pipe air into the house was so minimised by putting the pipe outside that it was worth while to do this, and after providing sufficient ventilation to run the risk. This brought him to his fourth head, the ventilation of soil-pipes and their disconnection from drains. Till within the last few years the size of ventilating or air-shafts to soil-pipes was 1½ in. to 1½ in., on 4, 5, and 6in. pipes, but in every good job the present custom was to carry up the soil-pipe full size. He was afraid to say the smallest word in disparagement of so good a rule; but it sometimes happened that a w.c. was wanted on the ground-floor of a very high building, and then it seemed an expensive arrangement to fix 5ft. or 6ft. of 4in. air-piping to ventilate 7ft. or 8ft. of 4in. soil-piping. In such a case he should fix 3½ in. soil-pipe, disconnect the soil-pipe from drain, or give it foot-ventilation, and if windows would not allow the termination of the air-pipe just above the soil-pipe, he should be satisfied with a 2in. air-pipe going up to roof—ventilating the trap of w.c. not with a branch-pipe. When a soil-pipe did not exceed 6ft. or 8ft. in length, and it was disconnected from the drain at its discharging end, and the w.c. was well supplied with water,

there was no necessity to fix a long length of air-pipe on the top. An air-pipe should never stop just beneath a roof-cornice, or there would be no escape for the contents except under the eaves. Generally soil-pipes were fixed, even in these enlightened days, with inefficient ventilation—i.e., they were not ventilated at the bottom as well as at the top, and consequently there could be no air-current through them. This was exemplified by a simple experiment with a stoppered glass tube. Whether soil-pipes were fixed externally or internally they should empty themselves into a drain outside the house, and when practicable the discharging ends should be exposed to the atmosphere. Where the pipe was carried up to ridge full size, there was no danger of offensive smell coming out at the grating enough to annoy anyone. Where such traps, from force of circumstances, would have to be fixed immediately under or near a window or door, seal over the top of trap, and take a fresh-air induct-pipe into its side. The fifth and last point as to soil and waste-pipes was the tacks for securing them in position. Single tacks should not be used, as neither so secure nor durable as pairs. A pair of tacks had double the strength of a single tack, for they had a greater grip of the surface, and they were also much stronger than a double tack. Tacks should be cut from a heavier quality of sheet-lead than the soil-pipe—say 1lb. per foot super. heavier. All those fixed on a stack should be cut out together to one size, and after feathering one of the edges with a rasp, each tack should be soiled about 3in. on the soldering face, and an inch on the opposite face. They should be shaved about an inch wide, and all the tacks should be fitted on the pipe so that they may be soldered on in one heat. In fixing a pair of tacks, pour the solder on each alternately, and then wipe them quickly one after the other. He would advocate the use of tacks on small air and waste-pipes, and these tacks were better than wall-hooks for fixing certain service-pipes, especially which might have to be removed to get at the fittings. In conclusion, the lecturer briefly touched upon general waste-pipes, urging that, instead of reducing such pipes to very small dimensions to get good flushes through them, it was better to increase the entrance way into such pipes.

The CHAIRMAN said such lectures must be of great benefit to the plumbing trade, as showing the principles on which fittings should be devised and made. The lecturer had omitted to mention that the Local Government Board's code of model by-laws, which were not, by the way, in force in the metropolis, the use of pan-closets was prohibited. He had recently seen a remarkable case of false disconnection at a watering-place; the soil-pipe was cut off beneath the floor of kitchen from direct contact with the sewer, and the result was to create a nuisance. Of course disconnection was useless, unless it took place in the open air. In the severe winter of 1879-80 he sent out a large series of questions as to the action of frost on soil-pipes fixed up externally according to his recommendations, and in over 100 replies there was but one which stated that the pipe was frozen up, and this, on investigation, proved to have arisen, as Mr. Hellyer had remarked was generally the case, from a leaky w.c. valve allowing water to dribble down the inside of pipe. Mr. Hellyer's desire appeared to be that plumbers should keep their minds open and free from prejudice, and he had himself set a very creditable example in this respect. On the cover of the first and second editions of his "Sanitary Plumbing in Sanitary Houses," Mr. Hellyer illustrated his patented three-dip trap; yet in his last lecture he had shown its defects, and had said that he could not recommend its use. The Council of the National Health Society were endeavouring to arrange for an evening's discussion on Mr. Hellyer's views.

Mr. PULLEN pressed that the last proposal—which had been received with loud applause—should be made definite, but the Chairman could not promise that. Mr. Pullen proceeded with great vigour to say that Mr. Hellyer's ideas of traps were all wrong, and that he could prove that the O-trap was better than either the S or U-trap. Interrupted by cries of "Question," he exclaimed that he was not talking to Bend and Dent's men, but to plumbers generally.

Mr. P. J. DAVIES said Mr. Hellyer had omitted to notice that in Bramah's closets a O-trap was always fixed underneath. He was proceeding when Mr. HELLYER held up Bramah's specification, and said he could not agree with a man who talked so, to which Mr. DAVIES retorted that he knew he could not, and the Chairman had to interpose between the lecturer and Messrs. DAVIES and PULLEN, who were all speaking at once, the latter exhibiting a model of a O-trap, which he said he would wager 5 to Mr. Hellyer's 1, was self-cleansing.

Mr. CHAS. GOSLING, of Pimlico, said he had been surprised to hear the lecturer say his firm still made hundreds (Mr. Hellyer: A few, only a very few) of the old-fashioned pan-closets. He should have thought that so large a firm could well afford to decline to execute orders for an article which one of its members had that evening entirely condemned as unsanitary, or else that they would label them "Bad; unfit for use."

Mr. HELLYER explained that the order came from an hotel where both proprietor and architect wished for pan-closets, and as his firm were taking the contract for plumbing-work, what could they do?

Mr. GOSLING: Refuse to supply or fix, certainly.

Another plumber said his specimens of plumbing work had been refused admission to the Sanitary Appliances' Exhibition to be opened on Saturday, because he had, in accordance with Mr. Hellyer's conditions, sent in under motto. It had cost him about £5 to prepare, and the loss of time and hire of conveyance to take to South Kensington, and he felt it wrong that it should be excluded on such a plea.

Mr. HELLYER regretted that red-tape should have intervened in such a matter, and promised to see Mr. Judge and get all competition plumbers' work sent to him (the speaker) shown. If necessary, the motto system should be abandoned. The would-be exhibitor said as that was the great guarantee of fairness, he should still decline to append his name to his work, and the meeting, which had been thinning during the after-discussion, broke up while Mr. Pullen was protesting against the attacks on the O-traps.

RESTORATION AT ST. ALBAN'S SINCE 1877.

THE following—taken from the *Herts Advertiser* is a report of the paper read by the Rev. Canon O. W. Davys, before the St. Alban's Architectural and Archeological Society, at their meeting reported in our last number.

On the 11th October in the year 1877, I read a paper on "The Restoration Works in St. Alban's Cathedral, finished, in progress, and to come," some portions of which may be in the recollection of the members of this society, and of others then present; my paper to-day will be in some sort a continuance of the same subject, for, as I formerly stated, it seems to devolve upon a secretary of the St. Alban's Architectural Society, founded as it originally was, for the especial study and care of a church which in interest (as one of my oldest architectural friends, Mr. Stewart, the historian of Ely, well wrote to me lately) "has not a companion," to report from time to time on its condition. It also seems the duty of such an officer to comment on the means taken for the preservation of so important a fabric, and the measures accomplished, or in contemplation, for the restoration of the several parts of the most vast of our existing Abbey Churches, and their adaptation to new uses in the Cathedral of one of the dioceses, the establishment of which will take a foremost place in the Church History of England, during the reign of her present Majesty. It may be asked why so long a period as four years has been suffered to elapse, during which so much that is important in the modern history of our Abbey has taken place, without any official report being made to this society; the fact has been that several "burning questions," as they have been called, have arisen in the course of the restoration works, and we thought it better to let them burn themselves out before commenting on them here. On a subject of very deep general historical and architectural interest, namely, the design of the west front, or rather the west fronts, of St. Alban's, as they were planned by the Norman and Early English architects, I read a paper before the Royal Archeological Institute, at their Lincoln meeting last year, which has since be-

come known through its publication in the *BUILDING NEWS* and other papers. I thought it better to read that paper before the most important architectural society we have in England, for two reasons; first, because the subject was one of far greater than local interest, and next because special circumstances made it better just then to take a view of our west front from a distance. In that paper I endeavoured to show, first what the west front of Paul of Caen, the great builder of the whole Norman structure, probably looked like when completed, and secondly how on the same ground-plan, which is nearly a fac-simile of the noble west front of Wells, John de Cella began and William de Trumpington continued, a grand Early English front containing, what no other English west front contains, the three magnificent porches seen in the great west fronts of France. I was able, from remains both of ground-plan and elevation, assisted as I had been, in some of my earlier researches, by Sir Gilbert Scott, to trace that west front up to the belfry stage of the side towers, which was probably as high as the work of the Early English architects rose. So far my paper dealt with matters of discovery, not of invention, as they were called in a subsequent article in the *BUILDING NEWS*, which accompanied a drawing of the proposed new front, of which the foundations are now being laid; the upper portions of the towers were perforce conjecturally drawn, as the Early English architects would probably have completed them if they could; but they appear to have been short of money then, as those, who would see them restored now, have found themselves lately. I may here mention that, in very notable instances, the builders of our great Early English Churches had to stop at their towers, the marvellous builder of Early English Salisbury, Bishop Poore, was translated to Durham, before he had completed his wondrous Cathedral of New Sarum, further than the supports of the central tower, and the tower and spire, which now rest on Poore's sub-structure, form, as you know, the grandest of the magnificent steeples of our Decorated period. Westminster Abbey had no towers completed till Sir Christopher Wren tried his hand at fancy Gothic at the west end. The towers of Lincoln are in their upper stages Decorated in the grand central tower, on an Early English sub-structure, and Perpendicular at the west front on the Norman towers of Remigius. Wells, our parallel west front as to ground-plan, has its towers at the west front Perpendicular, and most skilfully are they set on their lower Early English stages, the central tower of the Cathedral being somewhat earlier in date, while at Peterborough we have Decorated spires on the side towers of the Early English west front, and at Ely a Decorated octagon upon an Early English square western tower. It was for the benefit, upon the whole, of future generations, perhaps, that this delay in completing the steeples of our earlier churches took place, for there can be no question that, as decorative art and mechanical skill progressed we got far more magnificent, better proportioned, and more stable towers and spires erected. I should have been content then, and so probably would have been the majority of architects both professional and amateur, if, in the restoration of St. Alban's West Front, the lower stages of the side towers alone had been re-erected, leaving the superstructure to follow, if at all, at some future date. We should thus have got the glorious breadth, which our original architects intended, without striking the skyline with any new forms till after a long period of deep consideration. I was naturally, before the Archaeological Institute, reading a paper which dealt more with the antiquarian than the practical question of the restoration of this beautiful front, but I was attacked, in the discussion which followed, on two sides. A well-known architect asserted that though you might be able to trace the form and details of this front with perfect accuracy, though shafts and mouldings might be found, many of them *in situ* yet, since so much new work must be executed, you could only get a new front after all; to which my natural reply was, that, if this principle was to have so great weight, no restoration of a decayed building on the old lines was possible. Another gentleman flew off in a tangent at the horror of intrusting a restoration like this to one man, however generous; but the general sense of the assembly was evidently with the principles I had laid down, and their anxiety was to see as accurate a restoration of one of the

finest of our English west fronts accomplished as possible. I trouble you with this reference to my paper on the west front, because that must in many ways form a connecting link between my reports to the society of 1877 and 1881. I will now ask you to review with me the principal restoration works, which have been proceeded with since I last addressed you, and let me observe that those works have been both extensive and costly. We have been credited, I fear, by the outside public with being very highly talented in the art of quarrelling. Prose has not been spared to ventilate our grievances, nor poetry to celebrate our triumphs. I little thought, when, in my last paper before you, I spoke of the sunken roofs of our Cathedral, and a discussion subsequently took place on the question of elevating them, in which no less a member of our society than our present High Sheriff took part, that the first notes were being heard of the trumpet call to the great future "pitched battle of the roofs"; there seemed, at that time no immediate prospect of those roofs being touched; but events have moved rapidly. When that great mechanical work, to which I four years ago alluded, of forcing, by hydraulic pressure, the southern Early English compartments of the nave, which were leaning dangerously southward, into the perpendicular, and sustaining them in position by the erection of massive buttresses against the south aisle, and the completion of the vaulting within, was in progress, the decayed condition of the great nave roof became apparent, and measures had immediately to be taken which led in their result to the completion of the high-pitched roof of the nave, which we now see.

(To be continued).

THE CHICHESTER AND MIDHURST RAILWAY.

THE Chichester and Midhurst line of the Brighton Company, opened on Monday, is a continuation and extension of the Mid-Sussex, now absorbed in the Brighton Company's system. The section of the Mid-Sussex, of which the new connection is a continuation, may be said to commence at Horsham. A company to construct a line from Horsham to Pulborough was incorporated in 1857. The continuation to Petworth was purchased by the Brighton Company in 1860. The Mid-Sussex and Midhurst Company, for the construction of five and a-half miles, was incorporated in 1859. In 1868 a company for the construction of a line, of 13½ miles, between Horsham, Dorking, and Leatherhead, was incorporated. The Chichester and Midhurst Company, for a line of about twelve miles in length, was incorporated in 1864. The works were in part constructed by Messrs. Dearden and Buxton, contractors, but were stopped in 1866. In 1868 an Act was obtained authorising the abandonment of the project, and in 1873 another for its revival. The works for the revived line were commenced in 1878 by Mr. Thomas Oliver, of Horsham, contractor.

The new station at Midhurst—which is an ancient borough, and a market town—is, like all the others, in old English style, half-timber framing, built in red brick with Portland stone dressings, coved cement panels with floriated designs under the eaves, some of the gables faced with red tiles, and the windows filled with lead frosted cathedral-tinted glass. The roofs have terra-cotta finials and ridges. The entrance front elevation includes a porch partly open at the sides. A projecting portion of the front contains the stationmaster's house, with gable, mullioned windows, &c. The station buildings, which are on the up side, are 130ft. long; the platform on the down side is much longer, and has a large covered waiting shed. The roofs of the platforms are supported upon cast-iron columns and iron brackets. There is a subway under the line affording communication between the two platforms. The roof which is segmental, has 1ft. 5in. of brickwork and the invert 9in. The internal dimensions are from floor to crown 8ft. 5in.; width at floor 7ft., at spring of arch 8ft. The old station at Midhurst, which is at some distance beyond the new one, will be appropriated to goods traffic. All the stations on the new line, although varying in size, are alike in general style and character, and the description of the Midhurst station may be taken as applying to them.

From the station at Midhurst the line passes round a ten-chain curve, laid with a cheek rail. For the first three miles there are only two short cuttings, the remainder being on embankments of various heights. The cuttings referred to are not deep, and are through sand, of which there is an abundance in the district. It is sharp, and of excellent quality for building purposes. The line then passes for two miles over a chalk bank, till it reaches Cocking tunnel. The chalk from this tunnel and from the cutting beyond was taken for a lead of as much as three miles, between extremes of cutting and tipping. The tunnel is under Cocking-hill, which is at the summit 92ft. above the tunnel. Immediately before entering the tunnel the line is carried by a short embankment, 56ft. high at the deepest, across the Crypt ravine. The road to Chilgrove crosses under the line in the same locality. The tunnels are egg-shaped, 17ft. 6in. from side to side at the widest, and 8ft. 6in. from the rail level to the crown. They are of five-ring brickwork, and present elevations at the entrance in red brick, with white brick facings, and Portland stone caps and copings. The pilasters at each side are 4ft. on the face. They have entablatures, and rise considerably above the line of the panelled parapets. Cocking station is about two and a-half miles from Midhurst, and is 110ft. above the level of the preceding station. This station is near to the South Downs, the ridge of high land that extends from Lewes and the Valley of the Ouse on the east to Winchester, Salisbury, and the Valley of the Avon on the west. The Cocking tunnel is about 600 yards from the station, and is 788 yards long. It is on a gradient of 1 in 60 rising from Midhurst.

The headings of all the tunnels were driven at the bottom or formation level with shafts. At the Cocking tunnel a heading large enough for the passage of an engine and waggons was continued through the cutting at the south end of the tunnel, to open a way for the chalk to be carried to the tip at the north end. The making of the tunnel gave some trouble, from the looseness of the chalk and its liability to fall, especially after wet weather. About half-a-mile beyond Cocking tunnel the line reaches its summit—203ft. above Midhurst and 287ft. above Chichester. The line has risen by various gradients and pieces of level continuously from Midhurst; in like manner it now falls continuously to Chichester. At four and a-half miles from Midhurst, Drove tunnel, 710 yards long, is reached. The highest ground over it is 6ft., but between this and another ridge there are only about eighteen inches of ground between the natural surface and the brickwork. Before reaching the tunnel there is an embankment 28ft. at the highest part, followed by a deep cutting. The ascending gradients are 1 in 250, 1 in 160, 1 in 942, level, 1 in 105, 1 in 74, 1 in 88, level at Cocking station, and 1 in 60, which is the steepest on the line, and level at the summit; the descending gradient through Drove tunnel is 1 in 385. There was no engineering difficulty to encounter in making this tunnel; the chalk, firm and dry, is more intermixed with flints than at Cocking.

At five and a-half miles from Midhurst, and three miles from Cocking, Singleton station is reached; here the most important works upon the line have been carried out, heavy and costly, because of the nature of the ground, but chiefly from the accommodation that will be required by the visitors to Goodwood races. There are four lines of rails in the station, and sidings that extend for half a mile to the north, and a quarter of a mile to the south of the station. There is room in the sidings to accommodate fourteen trains of twenty carriages each, or upwards of 1,000 passengers. There are five water-cranes in the station, and an engine turntable, 45ft. 6in. in diameter. There is a large goods shed at one end of the station, 60ft. long by 30ft. wide, with sliding doors, verandah over loading dock, line of rails through the shed, and an office at one end. There are refreshment-rooms on both sides of the line. The next three bridges, which are over the line, are 25ft. wide between the parapets. The siding ends before West Dean tunnel, 441 yards long, is reached, the centre of it being about six miles from Midhurst. It is on a curve of thirty chains radius, and a gradient of 1 in 75. It is 112ft. below the highest part of the ground over it. At about a quarter of a mile beyond the tunnel the line passes under the Chichester high road by a tunnel bridge 10 yards long.

Lavant station, eight and three quarter miles from Midhurst, and three and a quarter miles from Singleton station, is on the west side of the line, close to the Chichester road, and adjoining Mid-Lavant Churchyard. After leaving the station the line again passes under the Chichester road by a wrought-iron girder bridge. This bridge has a skew span of 27ft. 4in. and a square span of 25ft. 11in. by 11ft. 6in., wrought-iron girders, with lin. tie bolt and arches in cement. Then follows a long shallow cutting in gravel, with slopes of $1\frac{1}{2}$ to 1; the cuttings through the firm chalk have slopes of $\frac{1}{2}$ to 1. From the cutting south of Lavant gravel was taken for ballast for the whole of the line. About a mile from Lavant Chichester cathedral and spire come into view, and a run of another mile brings the train to Fishbourne signal-box, where the road to Fishbourne crosses the line. From this point the new line runs alongside of the South Coast line of the Brighton Company for about three quarters of a mile, and forms a junction with it at Chichester station, which has been considerably enlarged and the platform lengthened to receive the Midhurst trains. A new goods shed, 115ft. long by 35ft. wide, has also been erected here.

The descending gradients from the level at the summit are—1 in 100, 1 in 385, 1 in 75, 1 in 60, 1 in 254, 1 in 75, 1 in 94, 1 in 272, 1 in 694, 1 in 81, 1 in 186, 1 in 76, level, 1 in 76, and practically level at Fishbourne crossing. The curves are very easy throughout, that at Midhurst station being on the shortest radius. The works, exclusive of cuttings, embankments, and stations may be thus summarised:—Three tunnels and a tunnel bridge, aggregating 1,965 yards lineal; one wrought-iron bridge under, and seven wrought-iron bridges over the line, fifteen brick arch bridges under, and three over the line; four bridges, or arches, with cast-iron bridges under the line for the accommodation of cattle, one over for the passage of the Lavant, and an ornamental bridge. The under bridges are built for a single line with a width of 11ft. between the parapets, except at Cocking, and three bridges near Singleton station, which are built for a double line, and are 25ft. between the parapets, which are 4ft 6in. high, with red or blue brick coping. All the over bridges are built for a double line, and one, north of Singleton station, has three lines of rails. All the brick bridges are single arch, with wing walls, newels, pilasters, and stone caps. At formation level the bases of cuttings are 19ft. for single, and 30ft. for double line.

The new line was laid out by Mr. F. D. B. Minter, engineer-in-chief of the Brighton Company; the works were executed under the supervision of Mr. Horace J. Mannering, as resident engineer, with Mr. J. Phillimore as clerk of the works. The stations are from the designs of Mr. P. H. Myres, of 21, Abingdon-street, Westminster, and Preston, Lancashire.

HARBOUR WORKS AT EAST LONDON, SOUTH AFRICA.

THE important works which have been in progress for several years at the mouth of the Buffalo River, South Africa, under the direction of Sir John Coode, are rapidly approaching completion.

Up to January 31 of the present year, besides wharves, sidings, and other collateral works, Sir John Coode states that the work done is represented by 3,150 lineal feet of training bank and breakwater on the east side of the embouchure of the Buffalo, by 1,550 lineal feet on the west bank, and by 1,230ft. of breakwater. The expenditure, including a sum of £50,000 for plant, workshops, and appliances, amounted on December 31 last to £306,964; but Sir John Coode fairly argues that the enterprise should be credited with the value of the considerable reclamations of land already and still to be effected by its prosecution. On the eastern bank an area large enough for a considerable township will be reclaimed, and here no doubt in the future the principal business in connection with the port will be transacted.

The further extensions proposed are the lengthening of the southern breakwater 290ft. from the point contemplated in 1877, the lengthening of the east breakwater 1,050ft., and the running on of the western training bank by 220ft. The gross estimated cost of the entire work is £521,200, and of the ultimate results to be derived from this outlay, Sir John Coode writes as follows:—"For some time past I have

considered that such an extension would be absolutely essential for the permanent formation of the channel, having regard to the rarity of the occurrence of freshets and to the almost incessant action of the surf. The proposed eastern arm will train the currents both entering and leaving the harbour, and place the entrance in a depth of over 22ft. at low water. Thus placed, I do not apprehend that the sand disturbances during gales will affect the depth, except to a limited extent, and there would thus, on the completion of these works, be sufficient water for heavy-draughted vessels to go into and out of the river at all times."

THE ARCHITECTURAL ASSOCIATION EXCURSION.

THE following is the outline of the programme as arranged for the excursion of the Architectural Association, which will commence on Monday, the 15th of August, and continue throughout the week. Mr. Aston Webb, the newly-elected president, will conduct the party, the number of which is limited to forty. On Monday, the opening day, Worcester Cathedral and adjacent buildings, including the Commandery, will occupy the whole day. Tuesday will be chiefly devoted to Tewkesbury Abbey, visiting the very interesting half-timbered house of Seven End on the way, with a half-hour's stay at Hanley Castle. Wednesday will, like the previous and two following days, be a carriage day, with Ombersley, Westwood House, Droitwich, Hadsor, and Mere Hall, as the places to be visited. On Thursday, Great Malvern and Ledbury, with its old timber market-house, will occupy the excursionists' attention, with 45 minutes' stay on the way both at Madersfield and Little Malvern. The half-timbered church of Besford, the most interesting of its kind in the county, is down for the first visit on Friday, when Evesham and the Abbey of Pershore will be seen. The concluding day, Saturday, will, like the first, be devoted to Worcester itself, including the churches of St. Andrew, St. Alban, and Holy Trinity, where the old Guesten Hall roof has been reused. The Guildhall, a veritable Queen Anne building, lately restored and added to by the late Sir Gilbert Scott, R.A., in conjunction with Mr. H. Rowe, F.R.I.B.A., the city architect, will also be visited. The head-quarters of the party will be the Star Hotel.

FRESCO PAINTING.

LEON BATISTA ALBERTI, the great Italian architect, in his well-known "*De Re Edificatoria*" (lib. vi) describes three varieties of *intonachi* for the walls; the first or rough coat is prepared to adhere strongly to the wall, and this coat supports the after-coats. It is a kind of rough-cast, and is called *zinzaffato*. The second coat is prepared with lime and clean river-sand laid on with a rough surface for the final *intonaco*, and is called *arriccato*. The lime is to be slaked in a covered trough with clean water added by degrees, till it is greatly in excess of the lime; the whole is then worked up with a spade until free from lumps. When this is done the fluid mass is covered up and left for three months or more to mature. A rough wall with joints, having projecting stones to form a key for the first coat, is recommended, and the first coat, or *zinzaffato*, is better applied when the wall is built. Messrs. Audsley, in their Dictionary, add that it was a custom with the artists of the fifteenth century to enlarge their original designs on the second coat with a pencil dipped in red colour (*rosaccio*), as by this means they could judge of the arrangement and scale. When amended, the red lines were traced on paper, which probably formed the full-sized cartoons. The *intonaco* was then spread over the *arriccato*, and the painting proceeded with. This process has been proved by examination of frescoes when the *intonaco* has fallen off. In the preparation of new walls for fresco painting much trouble, disappointment, and failure might be saved if the walls were built rough on the inside, and the coats of plaster laid on in the manner above described. Much failure has arisen from the lime not having been kept long enough, or the fact that it has not been well manipulated. The materials require to be evenly compounded and spread, and the sand well cleansed from saline and other impurities.

ALBERT HALL MANSIONS.

WE supplement our remarks on these mansions last week by a few words on the interior arrangements. The floors of each block provide suites of principal apartments, the other rooms of each set being in the basement and mezzanine floors. Taking one of the principal sets, we find on the ground-floor two suites of principal rooms, a vestibule and entrance-hall on the south side, common to the suites, a private hall and entrance, a dining-room, 28ft. 6in. by 16ft. 6in., a drawing-room of the same size, two bedrooms and a dressing-room, a w.c. and sink being placed in the lobby. There is to each set a stairs to basement and mezzanine floors; in the former is the kitchen, scullery, a bedroom, and cellar; and in the latter, three good bedrooms, with bath-room, w.c., and closets. The adjoining set of apartments is similar. On the first floor the suites are arranged on much the same plan; the dining-room is 23ft. 6in. by 17ft., the drawing-room 28ft. 6in. long by the same width, and these lead from a large inner hall, with entrance. These rooms front the park, and the projection of the front of drawing-room gives a balcony on the dining-room front. There are two bedrooms, a dressing-room, with conveniences, and stairs to mezzanine, where the kitchen is located. A service lift is provided. We may add the other two blocks are similarly planned, each pair of sets have staircases common to the whole block, besides private stairs. The rentals of each set range from £600 on the ground and first floors, to £150 on the third. The fourth-floor sets are to be let at £150, and the small flats at the top at £80 per annum. These mansions are let on lease only for 7, 14, or 21 years. Mr. Norman Shaw, R.A., is the architect, and Mr. J. Hussey, of Kensington, is the builder.

DRAUGHTS IN DWELLING-HOUSES.

DR. JAMES EDMUNDS, the Medical Officer of Health for St. James's, Westminster, in a paper contributed to the *English Mechanic and World of Science* on "Taking Cold," gives some particulars of some alterations introduced into a house under his direction with the view of avoiding draughts. He says:—

Last autumn, a gentleman residing in St. James's consulted me about a house which he proposed to purchase and move into, because he had never been well in his own. He had been for years a martyr to "bronchitis," and had always had his doctor in the house; although when away from his own residence he got on very well. In his house I found (1) no provision for the entrance of fresh air; and I pointed out that when fires were going, each of which carried up the chimney several cubic feet of air per minute, the same quantity of air must come into the house from outside, and that if he did not make provision for its entrance, it would be sucked in through the drains, or by down-draughts through other chimneys. In the first case he would be poisoned by sewer-air; in the second his house would be defiled by a sooty atmosphere; and, taking a lighted taper, I demonstrated that air was coming down certain cold chimneys, and bringing with it a stream of blacks, the heavier of which formed a deposit all round the fireplace through which the cold descending current came. It was the same with certain drains and waste-pipes, of which some are practically always left open. Now, dwelling-houses in winter are virtually supplied with foul air through the sewers, or with dirty air through the cold chimneys.

By a simple contrivance with the fanlight of the street-door and one of the lower sashes in the basement, I made a natural entrance for clean pure air to the central staircase. The "suck" of the chimneys was properly met; thenceforth the atmosphere of the house was all that could be desired and an obvious improvement in the cleanliness of carpets, curtains, &c., was observed. Further, to make each room supply itself more or less directly from the outer air when that was desired, I had the narrow bead at the bottom of each window-frame replaced by one from two to three inches in height—in fact, to come up nearly to a level with the opening for the window-glass. By this simple device (which also can be seen at any time in general action at the London Temperance Hos-

pital) the lower sash can be raised an inch or more, and thus, without any direct indraught at the bottom of the sash, the "suck" of the fireplace is met by an indraught at the top of the lower sash, the indraught being directed upwards and striking the ceiling obliquely so as to be fairly diffused through the room instead of striking upon persons sitting in the room. This arrangement is one that can scarcely be improved upon for ventilating an apartment, and it answers perfectly, subject only to the proviso that in very cold climates it is a better plan to supply each room entirely from the general staircase, the staircase being itself properly supplied with fresh pure air, which is warmed at the point of admittance by passing over steam-heated iron or copper tubing.

In cities like London the air should come in through a loose layer of cotton wool (like wadding ungazed) spread out between wire-work of an area adequate to admit sufficient air. The area of the wire-work should be about twice that of the sum of the areas of the largest number of chimneys that work together in the house during the winter months. The layer of cotton wool (or sheet of fine cambric) will need changing every now and then, according to the amount of soot and dirt which it has stopped and which otherwise would have been deposited upon the carpets of the house and in the bronchial tubes of the persons living in it. It is indispensable that this opening for the ingress of air be at the lowest point in the house, such as the hall-floor, or even at a basement window, as then the air does not find its way in unless in response to the "suck" of the chimneys; its ascent through the house is slow and uniform, and it is never felt as "draught." On the other hand, if a similar opening be made in a staircase-skylight, or the upper sash of a window be drawn down, the cold air comes in quite independently of the presence of "suck" in the room. The warm indoor air simply drains out of the house, and the cold out-door air simply drains in. This, which is a very general notion of "ventilation," simply wastes the heat inside the house, and causes a down-rush of cold raw air upon the inmates, a down-rush which takes especial effect upon those who are but thinly clothed upon the top of the head.

I found also (2) that a beautiful elliptical stone staircase in the centre of the house was lighted above by a large skylight. Openings in this skylight had been made for "ventilation," with the effect which I have described already, and which told upon the gentleman who, like myself, had lost his thatch, so that every time he passed out of his warm dining-room or drawing-room he began to sneeze, unless he put on a hat in order to pass through the staircase. The skylight also was constructed of one layer of thin window-glass, and the result was that even when these "ventilation" openings were closed up, there were mysterious draughts in the staircase (convection currents), which no one could understand, and which equally gave him cold. In fact, a gentleman of large fortune, in command of every comfort, and in one of the select residences of the West-end of London, had of late years found his London life one perpetual coddle and conflict with fits of sneezing and catarrh. Yet the cause of these mysterious draughts was very simple when pointed out. The warm air inside his staircase ascended in virtue of its lightness, and rested in contact with the under surface of the cold thin glass of the skylight. By this contact it was chilled, and thereupon becoming condensed and heavier than the lower strata in the staircase, it descended as a cold current, which, striking the head of my client, produced in him attacks of sneezing and catarrh, which never affected the well-thatched heads of the house-keeper or servants, and which, therefore, were set down altogether to constitutional tendencies to "bronchitis" on the part of the owner of the house.

This also was perfectly remedied. What I ordered was as follows:—The ventilation openings were sealed up, the lappings of the glazing were putried up so as to keep out cold air and blacks, and then a second horizontal skylight was set in beneath the other, it also being made air-tight, and there remaining an air-chamber between the two. The second skylight was glazed with thick sheet-glass; and with ornamental colouring it became a great addition to the house artistically. This arrangement practically proved non-conducting, so far as heat was concerned, and the "convection

currents," which had previously made the staircase impassable—even when all the "ventilation" openings were closed—were entirely stopped.

As a practical fact, these comparatively inexpensive devices saved this gentleman from the worry and expense of changing his residence. The atmosphere of the house is now sweet and clean; the warmth of the house does not radiate through the thin staircase skylight on cold nights. He is delighted with his residence; and the whole of last winter he passed in town without once getting fixed by his old enemy the bronchitis, and without once calling in his doctor.

Skylights ought never to be put up unless double or double-glazed. Double-glazing answers perfectly if the sashes are grooved out for glass on each side, and are then glazed with an air-space of $\frac{1}{2}$ in. or more between the panes of glass. The glass must be put in with its inner faces perfectly bright and clean, and the glazing should be done on a cold dry day so as not to include watery vapour, which, in cold weather, will condense inside the air-space and cause mistiness. This double-glazing with air-space makes a window almost as warm as a brick wall, and not only keeps up the temperature of a room in winter and saves firing, but it keeps the room cool in hot weather, and it makes the temperature more uniform throughout the apartment. With ordinary thin glazing in winter the inmates are always being chilled on that side which looks towards the window, and baked on the side which is towards the fire, and no sooner do ladies leave the dining-room than the gentlemen instinctively move up to the fireplace and proceed to bake the cold side of their persons. Double-glazing our window sashes would save all this trouble, and this device also may be seen in general use at the Temperance Hospital. So much for alternations of temperature, and for the methods of obtaining a continuous current of properly-tempered air through our houses in winter, without such currents striking the persons of the inmates, and thus giving them "cold." Such a current is *ventilation*—a current which strikes the person is *draught*.

In summer the problem of ventilation is a different one, inasmuch as there is no motive power at hand, such as the "suck" of domestic fireplaces. Open windows and doors must ventilate ordinary houses in summer. But in large buildings, such as crowded chapels, theatres, &c., the only method is to force fresh air into the centre of the building in such direction as not to strike the persons of those who are in the building. This must be done by a mechanical blower. Drawing air out of the building does not answer, inasmuch as the building is then supplied through windows, doorways, and objectionable channels, and the incoming current is sure to strike upon someone. On the other hand, if air be forced through a suitable trumpet-shaped tube into the central space of a large chamber, it need not strike upon any one, and the air finds its way not in, but out, through the doors, windows, &c. No better illustration can be given of the ignorance which prevails upon this subject, even in high places, than the theatre of the Royal Institution, where eminent scientists and aristocratic amateurs are herded together every Friday night under such physical conditions as to mutually poison each other. If a door be left ajar, there enters a draught which cuts like a surgical instrument, and which, acting upon the perspiring skins of the half-poisoned audience, must produce a regular crop of physicians' fees. I am sure that the illustrious professor of physics who presides over such matters there would rejoice at the results if every Friday night he would simply set one of his experimental gas-engines to work a blower which would discharge through a suitable shaft of not less than a foot in area, a stream of fresh, pure air upwards in front of the lecture table. No one could by any possibility be inconvenienced by a stream of air rising like a refreshing fountain into the centre of the theatre; the atmosphere would be kept perfectly sweet, and all the draughts which now cause so much unmusical growling in the neighbourhood of the doors, would go out into the empty lobbies, instead of piercing their way into a perspiring audience. The medical profession would suffer in pocket, but many eminent scientists would escape serious "colds," and "the aristocratic place out" (to use the words of Mr. Matthew Arnold, if I remember

rightly), instead of leading people to believe that ventilation is an insoluble problem, would teach a practical lesson in hygiene, which popular preachers and theatre-managers would not be slow to profit by.

ROYAL ACADEMY ADMISSIONS.

THE following are the Royal Academy admissions for July, 1881, to the Architectural Schools:—

TO UPPER SCHOOL.—F. B. Bare, W. Bucknall, J. F. Curry, B. Dicksee, E. G. Hardy, W. F. Lethaby, G. H. Shackleton.

TO LOWER SCHOOL.—G. Blizard, G. C. Horsley, H. H. Kemp, A. Kent, A. Leslie, H. W. K. Martin, H. G. Nixon, H. Read, T. Sims, J. A. Slater, R. E. Smith, C. H. Stock, W. Toogood.

PRIZE-WINNERS.—G. W. M. Addison, R. T. Blomfield, W. M. H. Burdett, F. Dickenson, H. Field, E. A. Jackson, F. Johnson, G. E. L. Lawrence, T. MacLaren, G. T. Oakesholt, S. Gambier Parry, F. Sanders, A. D. Smith, Kiugo Tatsuno, Thomas Ward.

CHIPS.

From specimens submitted, we think the testimonials accompanying them are well deserved, and that any readers desiring rapidly and correctly lithographed bills of quantities, plans, &c., will do well to employ Mr. J. L. Allday, of Colmore-road, Birmingham.

The parish-church of North Elmham is to be reopened on Wednesday, the 3rd August, after complete restoration of the roof, a work carried out by Messrs. Cornish, of that town; the interior of the church is about to be renovated.

The will of Mr. George Smeed, brickmaker, of Sittingbourne, who died on May 2 last, has been proved, the personal estate being sworn under £160,000.

A pair of three bells has just been cast at Reddenhall Foundry, Norfolk, for the parish-church of West Meston, Sussex.

A temporary line of railway from Hull to Eppleworth, near Wickenburg, was opened with public ceremony by the sheriff of Hull on Thursday week. It forms the first section of the Hull and Barnsley Railway, and includes an embankment two miles long, and several permanent bridges and a viaduct at Eppleworth. Messrs. Lucas and Aird, of London, are the contractors; Messrs. Shefford and Bohn, of Hull, the engineers, and Mr. J. Abernethy, F.R.S., the consulting engineer.

A brass eagle lectern has just been presented to Rottingdean Church, Brighton, which, we believe, was supplied by Messrs. Jones and Willis, of London and Birmingham.

A new workhouse infirmary has been completed for Worcester board of guardians. Mr. Rowe was the architect, and Mr. J. H. Beard the contractor.

An inquiry was held at Southampton on Thursday, the 7th inst., before Mr. S. J. Smith, C.E., an inspector of the Local Government Board, with reference to an application from the town council for sanction to borrow £1,092 for works of street foot-paving and improvement. The borough surveyor, Mr. W. G. B. Bennett, explained that the footpaths would be laid with Staffordshire blue bricks. The proposal, as reduced to £3,215, will probably be favourably reported upon.

The north porch of Salisbury Cathedral was thrown open on Monday week, on the completion of a restoration carried out as a memorial to the late Dean Hamilton, at the expense of his widow. The work has been carried out from the designs of Mr. G. E. Street, R.A., P.R.I.B.A.

One of the triforium corridors in the north transept of Hereford Cathedral is about to be filled with stained glass, as a memorial of the late organist. The work will be executed by Messrs. Clayton and Bell, of London.

The Scarborough school board have adopted plans prepared by Mr. John Petch, for the enlargement of Long Westgate school.

The Sussex magistrates received a report with reference to the surveyorships from a committee recommending three names out of 35 candidates, for the post of county surveyor, and two out of 15 for that of roads surveyor. The salary of the former will be 50 guineas per annum, with 5 per cent. commission on all sums above £20, and a guinea and a half for attendance at any bridge; that for the latter £100 per annum, these payments to cover all expenses. No decision was arrived at as to either election.

The new middle-class schools at Canterbury have just been completed. The architect was Mr. J. G. Hall, and the contractor Mr. Cozens, both of Canterbury.

NATIONAL SILVER MEDAL DESIGN FOR SHIELD.—DESIGN FOR TWO FRIEZES.—ST. NICHOLAS CHURCH, WHITEHAVEN.—CHURCH OF SAINTE MARIE-AUX-ANGLAIS, CALVAIOS.—NEW CRICKET PAVILION FOR THE UNIVERSITY OF OXFORD.—CURATOR'S COTTAGE, CAMBRIDGE.

OUR LITHOGRAPHIC ILLUSTRATIONS.

DESIGN FOR A SHIELD.

THE accompanying design, by Mr. Henry E. Tidmarsh, a student of the West London School of Art, was originally prepared in competition for prizes offered by the Goldsmiths' Company of London. The drawing, which is full-size, measures 2ft. 7in. in diameter, and is intended to be executed in silver repoussé and chased. "Republicanism, as a form of Government," is the subject illustrated. The six compartments around the centre contain representative scenes from the six principal Republics—viz., Greece, The Battle of Marathon; Rome, Junius Brutus condemning his two sons for participating in the rebellion; Venice, The Pope presenting to the Doge the ring with which to wed Venice to the Adriatic; England, Cromwell turning out the remains of the Long Parliament; America, The Signing of the Declaration of Independence; France, The Storming of the Bastille. These illustrate respectively the following qualities in Government: Patriotism, Justice, Prosperity, Order, Independence, and Liberty. These medallions are supported on either side by figures and their appropriate emblems, of the various Arts and Sciences fostered by a good Government. Round the border are small tablets, with the names of the existing Republics. In the centre of the shield is a symbolic representation of the Republic distributing favours equally to all classes, conditions, and sexes. Around this, in large letters, is the motto, "Liberty, Equality, Fraternity." The design was exhibited last autumn, amongst the works sent for examination to South Kensington, from the West London School of Art, and was awarded a National Silver Medal, &c.

DESIGNS FOR FRIEZES.

THE two designs for Friezes are by Mr. Edward Hammond, a student of the West London School of Art, Great Titchfield-street. One represents Orpheus playing in the presence of wild beasts—the rhinoceros symbolising Ignorance; the lion, Procity, &c., &c. This frieze is executed in colour, and will be used as a decorative panel for the front of a piano. The other frieze represents "A procession of the Planets," in which we see Venus, Jupiter, Neptune, &c. This has been executed in colour, and is intended for the decoration of a small cabinet. The above designs have been sent in for this year's National Competition at South Kensington.

ST. NICHOLAS' CHURCH, WHITEHAVEN.

Our illustration shows a south-west view of the new church of St. Nicholas, Whitehaven, now

in course of erection, from the designs of Mr. C. J. Fergusson, architect, F.S.A. Our view is taken from a pen-and-ink drawing, by Mr. E. F. C. Clarke, now in the Exhibition of the Royal Albert Hall of Arts and Sciences. The new church replaces a chapel erected by subscription about 200 years ago. It occupies a magnificent site, in the heart of the town, of some two acres, with streets on three sides of it. The High-street (if we may so call Lowther-street), from which our view is taken, runs along the western frontage, from which the church is set back a considerable distance. The design of the church is a simple rendering of Late Gothic type, and consists of nave, with aisles, chancel, vestries, and organ-chamber.

CHURCH OF SAINTE MARIE-AUX-ANGLAIS.

THIS is an excellent specimen of a small country church, chiefly of the Late Norman period. The details are well-conceived and well-executed; simple, suitable, and unpretentious. Both the name of the church and the style call to mind England—once the insular portion of Normandy. In the north wall of the chancel are two recumbent effigies of the 13th century, and there are still visible remains of wall-paintings in the chancel. It is sad to see how utterly neglected the whole place is. No service has been held in the church for some years, and nobody ever troubles to enter it except, perhaps, a "mad Englishman" or so. Indeed, there is only one house within about a mile, and the church stands slowly rotting away amid the heavy silent trees. In the doorways grow tall weeds, and the only practicable door opens after much resistance and many protests. The wind whistles through the broken windows; the plaster is peeling off; and a few more years will see the last of the paintings on the wall. Neglect and decay force themselves equally on the eye, the ear, and the nose, for the place smells like a dissecting-room. And yet the church is an admirable specimen of its period, still unrestored. Viollet-le-Duc mentions it in his Catalogue of Churches which attain to the dignity of "monuments historiques," (Dict. de l'Architecture, Vol. V. p. 172), and says:—"Petite église du XII^e siècle, composée d'une seule nef avec abside carrée; cette abside seule est voutée; elle conserve encore des traces de peintures du XIII^e siècle." The key is kept at the adjacent Manoir, a charmingly characteristic old place, guarded by the evil-looking dog that was ever seen. The nearest station is Mesnil-Manger.—J. A. G.

OXFORD UNIVERSITY CRICKET PAVILION.

THE new pavilion for the use of the Oxford University Cricket Club is built in the Parks, where a new cricket-ground has been lately formed. The building is designed by Mr. T. G. Jackson, M.A., and contains a large dining-room, a bar, with provision for cooking, a Committee-room, dressing-rooms for the members of the Club, and a room for the players. The principal front faces north to the match-ground, and has four raised terraces for seats, and a verandah, under which is a cellar for keeping the nets and other apparatus of the game. The three gables of this front are of oak timbering, filled in with plaster, and there is a turret for a bell in the roof. The walls are built of rubble stone plastered, with dressings of red brick. The contractor was Mr. A. Estcourt, of Gloucester, and the clerk of works, Mr. E. Long.

CURATOR'S LODGE, BOTANIC GARDENS, CAMBRIDGE.

THE house which we illustrate to-day was built by the Botanic Garden Syndicate, at Cambridge, from the design of Mr. W. M. Fawcett, M.A. It is a small house with two sitting-rooms, kitchen, &c., four bed-rooms, and small bath-room; there is also an office for the curator and the syndicate. It is built of red brick and has bay windows. The barge and cornices are all of wood. The lodge stands near the side-entrance from Panton-street, and this is most used for the general management of the Gardens. The principal aspect is south, and the windows have a good view of a large portion of the gardens.

The new bridge which has been erected across the Dee at Aberdun, in the line of Market-street, was formally opened on Saturday afternoon. It is of granite, and consists of five arches. Mr. Blyth, of the firm of Blyth and Cunningham Edinburgh, was the architect, and Mr. John Fyfe, of Kenney, the contractor; the cost has exceeded £20,000.

COMPETITIONS.

WINDELMERE CHURCH COMPETITION.—We hear that the result of this competition (as far as it is at present decided) is that the selected design is the work of a young gentleman, the son of a local builder, and at present a pupil in the offices of a firm of architects of Carlisle. The matter, however, is in abeyance pending the consent of the firm in question being obtained to the successful competitor being allowed to proceed with it. We hear also that the design of Mr. D. Brade, of Kendal, was placed second, and that of Messrs. Holton and Connon, of Leeds, third. There is considerable dissatisfaction at the result, which was fully anticipated by some from the commencement, and it has led to the retirement of some of the influential members of the committee and subscribers.

FOREST OF DEAN.—Mr. Alfred Smith, of Mitcheldean, informs us that his designs have been accepted by the Forest of Dean School Board for the following works:—Steam Mills Schools, Forest of Dean, Gloucestershire, for 416 children; Joy's Green Schools, for 274 children, and a separate teacher's residence. They have been passed by the Educational Department, and are to be proceeded with at once.

HOTEL ON THE THAMES EMBANKMENT.—With reference to the limited competition to which we referred last week for the erection of a new hotel and residential chambers on the site of the now abandoned National Opera House on the Thames Embankment, the following is a list of the architects who have sent in designs:—Messrs. Francis and Saunders; Fowler and Hill; Verity and Hunt; Hunt and Steward; Isaacs and Florence; and Mr. Ed. Grüning.

CHIPS.

Horncastle's Newspaper List, prepared by Mr. Horncastle, of 61, Cheapside, besides the usual features of such a publication, contains a readable and very intelligently written preface, which should be read by all advertisers.

A stained-glass window, to the memory of the late Earl of Elgin, Governor-General of India, was last week placed in the south transept of Duunfermline Abbey.

The parish-church of Ilanlyfring, in the diocese of St. David's, is about to be rebuilt from plans prepared by Messrs. Middleton, of London and Cheltenham.

A new church is about to be built at Cwmbach, Aberdare, from the plans and designs of Mr. Edwin M. B. Vaughan, A.R.I.B.A., of Cardiff.

The following works, in connection with the new St. Marylebone infirmary at Notting Hill, were executed by Messrs. Thomas Potter and Sons, of 44, South Molton-street:—Steam boilers, engine, pump, all cold water tanks, main pipes and branches, fire-main and hydrants, hot-water heating apparatus, hot and cold supply to baths and lavatories, 8 hydraulic lifts, drying-closet for laundry, disinfecting closet, wrought-iron external railing, thermohydric stoves for heating wards.

The theatre royal at Wardsend, Halifax, is being enlarged and reconstructed under the supervision of Mr. Richard Horsfall, architect, of that town. A promenade is being provided under the dress-circle, the stage lowered 4ft., the pit enlarged, and new dressing-boxes provided; the alterations furnishing additional accommodations for between 600 and 700 persons.

The Episcopal church of St. Michael, Aberlour, has been formally consecrated by the Bishop of Aberdeen. It is built of Hopeman freestone and Duftown limestone, and consists of nave and chancel 63ft. by 24ft., and 35ft. high from floor to apex of open roof of nave. It cost £1,000, and seats 100 persons. The architect was the Rev. C. Jupp, of Aberlour, the founder of the cause.

Sir Joseph W. Buzalotte, C.E., the Mayor of Devonport, and several members of the Stonehouse local board recently made an official inspection of the tunnel sewer, from Eastern King's Point to the northern end of Durnford-street, just completed at the joint cost of the authorities of the War Department and of Devonport and Stonehouse. The work, which has been in progress for two years, has cost £19,000 instead of £15,000, as originally estimated, the extra cost being occasioned by faulty geological strata.

Mr. John Hocking, C.E., died at his residence at Redruth, on Saturday, aged 75. He was well known throughout Cornwall as a civil and mining engineer in extensive practice, and also as the proprietor of a safety fuse factory.

ASPHALTE.

A LECTURE on "asphalte" was read by Mr. E. B. Bell, C.E., before the members of the Balloon Society, at the Westminster Aquarium, on Friday evening. The material was, it was shown, a natural production, consisting of from 5 to 15 per cent. by weight of pure bitumen combined by carb nate of lime. Although its composition was well known, and the components could be derived in abundance, and at moderate cost, asphalte had not yet been artificially produced with success, either chemically or commercially. Its employment was of the highest antiquity, it having been well known to the Egyptians, Assyrians, and Babylonians, although, curiously enough, no allusion to it was made by Roman or Greek writers, nor could it be found in the works of those Classic nations. It appears to have been rediscovered by Dr. D'Eyrinis, who published a work in 1721, enthusiastically advocating its use, not only as a cementitious material, but as a universal panacea in medicine. Dr. D'Eyrinis found out the material while making a geological excursion in the year 1781, the Val de Travers, canton of Neuchâtel, Switzerland, and for nearly a century this was the only mine worked. In 1838 the first footpaths were made in the material at Paris, and the Seyssel mines were opened; but owing to commercial speculations, asphalte lost favour, and it was not till 1854 that the first Parisian carriageway, that of the Rue Bergère, was paved with it. Since 1871 a very large proportion of the streets of Paris, both the carriage and footways, had been laid with asphalte. The first experiment in London was in May, 1869, when 485 square yards of Threadneedle-street were laid with it, and its use had been largely extending. The material was at first used as mastic, boiled on the spot in large cauldons, but latterly it had been found better to use it as a powder, rammed by manual pressure. The present treatment was that the rock was brought to England and stored in the open. It was thrown into a stone-crushing machine, and having been reduced to piece about the size of a walnut, the material fell on to a shoot, from the bottom of which an endless chain of buckets carried the material to the hopper of a Carr's disintegrator, in which it was reduced to powder. It was then heated in cylinders over a coal fire. Each charge consisted of about 2½ tons, and took from two to three hours to attain the requisite temperature, and varied according to the amount of vapour to be driven off, and had to be very delicately regulated. If the material was not sufficiently heated, it would not adhere enough under compression to give the laid surface a hard face. If, on the other hand, it was overheated, the bitumen was fused and little but comparatively worthless limestone left; as a rule, the heat varied from 220° to 250° Fahr., but much was left to the experience of the skilled calciner. The powder was now ready for laying, and owing to its dense, compact nature it would retain the heat for many hours. A concrete foundation having been laid and allowed to set firmly, the asphaltic powder was brought to the street in open carts and spread transversely across the carriageway in widths of from 3ft. to 4ft., in a thickness about two-fifths above the specified compressed section. It should still have a minimum temperature of 115° Fahr. It having been raked with as much regularity as possible over the concrete, the powder was rammed all over with heavy iron, mushroom-headed punners, heated in portable furnaces to a temperature that prevented adhesion. This ramming was the crucial point of the operation, and was at first done very lightly, the pressure being augmented as the material attained solidity. An opening presented itself to mechanicians to devise some mode of mechanical ramming; many plans had been suggested, but at present none had answered. The objection to rollers was that they drove the powder forward in a wave, and the force was not advantageously applied; a steam hammer executed the work better, but the practical difficulty of laying the temporary rails had been fatal to the method. After the surface was compressed by the punners, the surface was seared with a smooth iron, and it was gauged by a long straight-edge, beaten to a uniform level, and the roadway was finally thrown open for traffic as soon as it had cooled to the temperature of the atmosphere. The lecturer then indicated the advantages of the asphalte as a paving material from the sanitary, mercantile, ratepayers', and humanitarian points of view.

He thought all would agree that that material was best for roadways which created least dust and mud, presented the most continuous surface, and retained least damp. Dust in itself, apart from its impure character, was injurious to health, and was rendered worse by the deleterious substances contained in it. Asphalte stood foremost, he held, in its imperviousness to filth and moisture, and hence no exhalations could pass through it from the ground below, nor did it suffer any change under moisture. It was also almost noiseless, and although exceeded in this respect by wood, asphalte had not the peculiar rumbling sound which that material caused. To the mercantile portion of the community it was not only commended by its freedom from dust and mud, but from the absence of vibration, and the minimising of traitle force needed to draw given loads. The unpopularity of asphalte with many engineers and architects arose from the fact that streets were laid with preparations of gas-tar, or pitch and limestone, or clay, which resulted in a soft surface during the first year or two, giving off oils by evaporation, and breaking up after two or three years' wear. The cost of cleansing and watering was greatly reduced by the use of true asphalte. Comparisons made by Lieut.-Col. Haywood, the City engineer, showed that one cart-load of refuse was swept from every 344 square yards of macadam, from every 500 square yards of granite, from 1,666 square yards of wood, whereas 4,000 square yards of asphalte had to be traversed before a load was obtained. The expense and inconvenience of renewal was also reduced. One of the greatest conveniences for a crowded city was the fact that an asphalte roadway once down, the street need never be blocked for repairs. Cheap-side had now been laid for eleven years, and the traffic had never been interrupted for an hour during mending. The watering, again, was reduced to the flushing of the channels with streams of water. The common objection to asphalte was that it afforded a bad foot-hold to horses. In itself, however, whether dry or quite wet, it was not slippery, but when the air was humid and after slight dirt upon the surface rendered it greasy. Lieut.-Col. Haywood had proved by statistics that fewer horses fell on asphalte than on granite, and this was confirmed by much independent evidence. Further than this, horses hurt themselves the less by a fall on asphalte than on granite. It was chiefly on the transition from one material to another that accidents occurred, and the true remedy appeared to be to lay all with the same class of paving. In conclusion, the author showed that amongst the other uses of material were in flooring warehouses and granaries, for which its imperviousness to damp and vermin strongly recommended it.

A discussion followed the reading of the paper, in which the chairman (Mr. W. H. Le Fevre, C.E.), Col. Bryne, R.E., and Messrs. Ford, Burton, Harrison, Piper, Read, Durrant, and others, took part. Some questions were asked as to original cost and outlay of maintenance as compared with other materials, to which Mr. Bell replied that the two should be taken in conjunction, when the balance was slightly in favour, he believed, of asphalte; the first consideration he urged with a local authority should be, What was the best paving material? The discussion turned chiefly on the question of how to reduce the admitted greasiness of asphalte when in a semi-moist state. Flushing with water was said to be a remedy; Mr. Ford, as surveyor of Bermondsey, said he thought he had tried an original cure—viz., that of sprinkling with sawdust, and that the result had been very satisfactory; Mr. Durrant had found ordinary gravel, thinly applied, useful; but Mr. Harrison pointed out that the rounded particles of sand or gravel lessened the grip they afforded; he, as a surveyor, had tried with success emery, sparingly applied, which was, when a road was greasy, well worth its cost, about 2d. per lb. Several speakers pointed out that both emery and gravel cut into and destroyed the asphalte, and had very soon to be swept off as mud, and the meeting was closed with a vote of thanks to Mr. Bell.

The parish-church of Portsmouth, near Kingsbridge, South Devon, has been repaired after restoration from the plans of Mr. J. Pies St. Aubyn, of the Temple, London, at an outlay of £2,000.

Building Intelligence.

BIRMINGHAM.—The Birmingham Liberal Club having so considerably increased as to render a larger building desirable, a committee was appointed some time ago to consider and report upon various sites for the proposed new club-house, and to prepare plans of a suitable building. A meeting of the general Committee of the Club was held last week to receive the report of the Sites Committee. Designs for a club-house, prepared by Mr. J. A. Cossins, the architect of the Mason College, were submitted by the Sites Committee, and were admired for their handsome appearance and for the accommodation provided by the plans. The estimates of cost and of probable income, submitted with the plans, were considered very satisfactory; and the report and the design were approved, and ordered to be presented to a general meeting of the members of the club for consideration.

CARLISLE.—The new Great Central Hotel at Carlisle was opened on Saturday last. The exterior of the building may be described as Queen Anne in character. It is of bold design, and the building is all of the most substantial character. Mr. Westmorland, the proprietor, executed most of the work himself, but he let some portions which may be specified. Mr. Anderson, of Glasgow, executed the plumbing; Mr. Ormerod, of Carlisle, the cement corridors and floors; Mr. Ferguson, of Carlisle, the plaster-work; Mr. Graham, of Carlisle, the iron work; Mr. Waddell, of Carlisle, the electric bells; Messrs. Forest and Son, Liverpool, supplied the ornamental glass; Messrs. Holgate and Fishwick, Liverpool, the bar fittings. The walling stones, of white Lazonby, were supplied by Mr. W. Graves. The stone-carving was done by Mr. Gedding, of Carlisle. Mr. Daniel Birkett, F.R.I.B.A., of Carlisle, was the architect.

DOVER.—A new town-hall and block of municipal buildings are about to be erected adjoining the Maison Dieu Hall, at Dover. The works include an assembly-room 79ft. by 57ft., and 36ft. high, communicating by corridor with the Maison Dieu, and beneath this will be offices for town-clerk, borough-surveyor, and other officials, and adjoining will be a clock-tower. The buildings will occupy the site of the prison, the Kentish ragstone from which will be used for foundations. The estimated cost is about £17,540. The preparation of the plans was undertaken by the late Mr. William Burgess, A.R.A., and the details have been worked out by his chief assistant, Mr. Chappell; the works will be carried out by Mr. Burgess' brother-in-law and successor, Mr. R. Popplewell Pullan.

FULHAM.—All Saints' Church, Fulham, was consecrated on Saturday last. The gas arrangements were carried out by Hart, Son, Peard, and Co., Wych-street, Strand. The pulpit, octagon in plan, Bath-stone base, moulded and figure-carved at angles, and oak top with open carved panels; also altar-table, credence, and sedilia, in oak, were executed by Mr. Eadp. The tiles for chancel and nave were from Godwin's, of Lugwardine, Hereford. The seating in nave and aisles, also transepts, is of pitch-pine, and choir-stalls are of English oak. The architect was Mr. A. W. Blomfield, and Mr. John Vaughan was the clerk of works.

NORTHWICH.—The foundation-stones of a school-chapel, in connection with the United Methodist Free Churches, were laid on Tuesday last, in Penny-lane, Witten, Northwich. The site is on the easterly side of Penny-lane, and the front of the building will be 26 yards back from the lane, thus leaving a good site for a large chapel, which it is proposed to build in the near future. The building will be a neat, plain structure, and will comprise a school-chapel capable of seating 180 adults, two large vestries, and a store-room, with tea-boiler and heating-apparatus cellar underneath. There will be two entrance-porches, for the use of boys and girls respectively. At the rear of the site separate yards and offices will be provided for the scholars, &c. All outside walls will have 3in. cavities, and will be built of brick, with Eddisbury red-stone dressings. The internal woodwork and fittings will be of the best

pitch-pine, twice varnished. The premises will be heated by means of hot water. The inlet of fresh air and the expulsion of vitiated air will be effectually provided for. The plans have been prepared by Mr. S. Hurst, of the firm of Maxwell, Tuke, and Hurst, architects, Southport, and the buildings will be erected under the architect's personal supervision. Messrs. Leicester, Bros., joiners and builders, Northwich, are the sole contractors.

OLDHAM.—New board-schools at Roulthorn, near Oldham, were recently opened. They are Gothic in style, and are built of brickwork with a base of coursed pitch-faced wallstones. The mixed school is 51ft. by 25ft.; there are also two class-rooms 29ft. by 25ft., and 22ft. by 16ft., two infants' rooms, one 28ft. 6in. by 18ft., the other 18ft. by 16ft., and a teacher's room 11ft. by 13ft. The rooms, instead of the usual windows, are lit by large skylights in the roofs, made to open. The architect was Mr. William H. Cooke, of Queen-street, Oldham.

SOBERTON, HANTS.—On Wednesday, June 29, St. Peter's Day, the parish-church of St. Peter, Soberton, was re-opened by the Bishop of Winchester. Soberton church consists of nave and aisles, chancel, with north aisle, south transept or maorial chapel, and western tower. The church had been allowed to fall into an exceedingly bad state, and injudicious repairs, made some thirty years ago, had detracted considerably from the architectural interest of the fabric. The plaster ceilings in nave and south aisle have been removed, the old oak roofs exposed to view and re-tiled. The modern and insecure roofs over north and chancel aisles have been replaced by others of a more suitable character. The walls and windows have been thoroughly repaired, and the latter reglazed throughout. Most of the walls also required re-plastering inside. Floors have been relaid with Minton's and other tiles, and new open seats have taken the place of the pews, which had been made out of a variety of old materials at the time of the previous "reparation." New oak screens have been made, from the architect's designs, and inclose the vestry and the ground or ringing-stage of the tower, and a new half-timbered oak porch has replaced a modern brick one of very poor character. The repair of the tower required much anxious consideration and care, opening into the church in a very unusual way with three arches. The main supporting piers, of weak construction, were being crushed by the great weight of the tower, and it was necessary to rebuild them. Elaborate precautions in shoring and centring were taken the tower supported, and the old piers pulled down and rebuilt in a sound manner. When the temporary supports were removed not the slightest settlement took place. The tower was further strengthened by iron ties, the bells re-hung, a new lead roof provided, and the masonry thoroughly repaired throughout. Mr. Charles Richard Pink, M.R.I.B.A., of Castle Hill, Winchester, and Westminster, was the architect of the work, and Mr. W. Green, of Meonstoke, the builder.

CHIPS

Mr. Rhind, of Inverness, has been appointed architect for the proposed mechanics' hall for Fortree, N.B.

The extension of the Albert Dock at Leith has just been completed, having occupied a staff of 600 to 700 men during the past six years. It occupies 100 acres of waste foreshore formerly known as the Leith-mills. This has been inclosed by a wall one mile in length, built in concrete blocks, weighing 4 tons each. Within this the docks have been dug out, and are divided by a graving-dock placed in the centre of area, and measuring 359ft. by 18ft. The stone employed for quay-breasts and buildings is granite from Craigmillar quarries, beyond Edinburgh. Mr. Scott, of Edinburgh, has been the contractor. The new portion will be opened by the Duke of Edinburgh, and is to be known as the Edinburgh Docks.

A loan art exhibition is to be held at the town hall of Stroud, N.B., in October next.

New premises for the Dorset County Museum are being built at Dorchester on the site of the old George Inn. Messrs. G. R. Crickmay and Son, of Weymouth, are the architects, Messrs. Gay and Son the contractors, and Mr. Storey is the clerk of works.

The Kent and Ashford industrial and fine-art loan exhibition will be opened at Southcote on August 4th. Over 1,000 exhibits have been accepted.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

CUMBERLAND AND WESTMORELAND ANTIQUARIAN SOCIETY.—The thirteenth annual meeting and excursions of this society were held at Kendal on Thursday and Friday last. On the first day Sizergh Castle, the seat of Mr. C. W. Strickland, was the principal item of the programme, and the party were shown over the building by the Rev. James Gibson, of Kendal, being shown the tapestries, family oil portraits, inlaid parquet-work and armour, in which this interesting building is rich. Low Levens Farmhouse and Levens Hall were described by Canon Weston in a paper, and orally by Mr. C. J. Fergusson, F.S.A., of Carlisle, and Mr. Jackson. On the second day, Skelsmergh Hall, Barneside Hall, the ancient Chapel of St. Anne, Grassgarth, a British settlement at Howgill, and the old church of St. Catherine, at Crook, furnished a full day's work.

NORFOLK AND NORWICH ARCHÆOLOGICAL SOCIETY.—The annual excursion of this society was made on Wednesday week to some parishes in the Grimshoe Hundred it had never before visited. Leaving Lakenheath Station about 10 a.m., Hockwold Church was first seen, a paper being read here by the Rev. A. Sutton. The church is a small structure, dedicated to St. Peter. The best features are the square west tower, which was apparently intended to be crowned by a stone spire, and the fine, but now greatly dilapidated, nave roof. St. James's Church, Winton, was next seen, under Mr. Sutton's guidance; nave, chancel, tower, spire, are one uniform style, and all remarkably free from ornamentation. The screen, of curved oak, was restored by a late curate of Feltwell with his own hands, and the thatched roof has been recently replaced by a covering of slate. At Feltwell, the two churches were seen; that of St. Mary, the only one in use, being the first seen; it is a large-aisled structure, with richly treated hammer beam roof, having angel corbels, and a heavy shower afforded ocular demonstration of the bad state of repair into which this fine feature has been suffered to lapse. The other church, St. Nicholas, used as a mortuary chapel, has a round tower, and arches of Transitional Norman character; the chancel was demolished in 1862. At Methwold, the large parish-church, having a magnificent angel-and-hammer-beam roof to nave; and the vicarage, built in the reign of Henry VII., were the chief objects of interest. The vicarage is now partitioned off into cottages, and the oak is whitewashed and broken. The last church visited was St. Andrew's Church, Northwold, where the Rev. C. R. Manning acted as guide. The roof is another good specimen of the Norfolk Perpendicular type, but was repainted and gilded in 1815. Every style, from Early English to Late Perpendicular, is represented in the church, the most remarkable feature being the Easter sepulchre, said to be the largest in the kingdom; it measures 9ft. long, and 12ft wide, and is of clunch; the lower part bears mutilated figures of the four Roman soldiers on guard at the tomb, and above are ornamented niches and three richly-roined canopies.

ARCHÆOLOGICAL.

BOADICEA'S CAMP.—The camp of Boadicea, Queen of the Iceni, has been found. In Epping Forest she may have,

Standing loftily christened
Met and mingling all that heard her in her fierce
volubility,
Yelled and shrieked between her daughters o'er a wild
contumacy.

Morant, in his "History of Essex," has pointed out a certain spot as her camp. The Essex Field Club has been investigating, digging and delving about this place, and the result is to make it as probable as such things can be that Morant was justified in his assertions. General Pitt Rivers is preparing a memoir on the subject.

CANTERBURY.—A discovery has been made in Canterbury of the foundation of a Romano-Saxon church. Recent workmen were engaged in digging a foundation for a disinfesting chamber in one of the cellars of the Kent and Canterbury Hospital, when they came across an immense quantity of human bones, which were piled up to a depth of nearly three feet. These were removed to the hospital cemetery, and in making a receptacle for them the foundation of

the old church of St. Pancras was discovered. The Rev. Canon Rountledge had his attention drawn to the discovery, and he consulted an old Latin volume which he found in the cathedral, written by a Benedictine monk of the fourteenth century, which gives a full description of the church. Under Canon Rountledge's instruction further search was made, and eventually the entire foundation was discovered of a Romano-Saxon church built about the beginning of the fifth century. There were also found an altar, which, it is thought, is the very altar at which St. Augustine celebrated mass, and a tomb in which were bones. The tomb is of a very rude description, consisting simply of a stonework built round the corpse. Mr. Roach Smith has been to Canterbury and examined the foundation of the church and other relics; and when the Kent Archaeological Society visit the city shortly, further inquiries will be prosecuted into this most interesting discovery.

PALESTINE EXPLORATION.—The July number of the *Quarterly Statement*, issued in connection with the Palestine Exploration Fund, contains full particulars of the very remarkable discoveries which have been made in the last few months. First in interest, perhaps, comes Professor Sayce's commentary on the newly-found inscription at the Pool of Siloam. A text which dates from the time of Solomon is indeed a rare monument. There is next a discovery made by Lieutenant Conder, which may prove of even greater interest. He has found, close to the spot where he places the site of the Crucifixion, which is still called the Place of Stoning, a Jewish tomb of Herodian period, standing alone, cut in the rock. "Can this be," he asks, "the 'new Sepulchre in the Garden'?" A drawing and plan of the tomb have been made for the society. Another drawing has been made of the real mouth of Jacob's well, recently uncovered by the Rev. C. L. Birdsey. The well-mouth is much worn by the friction of ropes. It was formerly covered over by a Christian church, and if, as is possible, this church dates back to the second or third century, the stone should be no other than the very stone on which our Lord conversed with the woman of Samaria. Another discovery, only indirectly connected with the Bible, is that of the ancient Hittite city of Kadesh, on the Orontes. Not the least surprising thing about this are the facts that Lieutenant Conder found it from an Egyptian record written 3,000 years ago, and that the old name, though it has disappeared from history since the 13th century before Christ, is still attached to it.

PREPARATIONS are being made at Berlin for an heraldic exhibition, which is to be held there in April and May, 1882. It is intended to be as complete as possible, at least so far as Germany is concerned, in the departments of heraldry, genealogy and family history, and seals. Its success will, of course, depend mainly on the co-operation of the German noble families, whose archives and muniment-rooms must be the chief sources whence its objects will come. It is hoped that foreign countries also will send contributions. Among the classes of things which the committee hope to see exhibited, the following are enumerated:—Heraldic helmets and shields, mediæval weapons, heraldic paintings, and manuscripts; books of descent, arms, letters of nobility; patents and charters having interesting seals; genealogical trees and tales, family records; goldsmiths' work bearing heraldic emblems and ornaments; heraldic devices in various metals; stone, metal, and wood carvings; domestic utensils having heraldic emblems in porcelain, glass, or stone; similar articles in women's stuffs, embroideries, laces, carpets, coverlets, table-linen, curtains, wearing apparel, and robes; tapestry, banners; articles of ivory, leather, mother-of-pearl, &c., having heraldic ornaments, &c. The gem-engravers have signified their intention of sending valuable contributions, and have asked that a special apartment shall be assigned to them. It is expected that the municipal bodies will be prominent and splendid contributors. The city of Breslau has promised to send a series of manuscripts and objects, both genealogical and heraldic, which will be equally important and interesting.

THE ANTIQUITIES OF CARNAC.—A portion of the proceedings of the Archaeological Society of France during their meeting held at Vannes was occupied with a record of the labours

undertaken and carried to a successful issue, after a full period of seven years, in the neighbourhood of Carnac, Brittany, by the late Mr. James Miln, whose book we noticed a fortnight since. The relics exhumed under Mr. James Miln, and at his personal expense, have found a permanent location near the spots whence they were obtained. A museum, which is to bear the name of the Musée Miln, is in course of erection at Carnac, by order and at the expense of his brother, Mr. Robert Miln, the building and the collections which it is designed to contain being vested in perpetual and joint ownership in the Municipality of Carnac and the Philomathic Society of Vannes. This collection, thus liberally presented by Mr. Robert Miln as a memorial of the deceased antiquary, makes the Département de Morbihan one of the richest in prehistoric documents, Vannes already containing two noted depositories—one the City Museum, and the other the private collection, always accessible to students, of M. le Comte de Limur. In recognition of the eminent services rendered by the late Mr. James Miln in the cause of the archaeological monuments special to the Morbihan, the French Society, at their final meeting awarded to him the posthumous honour of their great gold medal, which will be deposited in the Miln Museum at Carnac.

AZTEC CALENDAR STONE.—The *New York World's* correspondent at Mexico reports the discovery of a new Aztec calendar stone. It was found, June 2, by Captain Evans under a dilapidated Indian hut, which stood on the place that once formed the favourite garden of the Texcocoan "Poet Prince" Netzahualcoyotl. It is a stone slab, 8ft. by 6ft., covered with hieroglyphs, and near the centre of it is a clearly cut calendar—similar to the far-famed "Aztec Calendar stone" which is now attached to the cathedral in the city of Mexico. The stone goes to the Mexican National Museum. Further excavations are to be made on the same site, and since King Netzahualcoyotl "the Wise" built his palace on a hillock on which the residence of the sovereign lords of a more ancient nation had stood, it is probable that further researches in that locality may lead to interesting discoveries.

ARCHAEOLOGICAL DISCOVERIES IN OXFORD-STREET.—During the past week, in the course of the demolition of some old buildings at 406 and 407, Oxford-street, a number of objects interesting to antiquaries were brought to light. The premises where the discovery was made are situated in the rear of the north side of Oxford-street, near its intersection with Tottenham-court-road. On Wednesday week, the workmen, on reaching the foundations, came upon a quantity of old armour and weapons—helmets, breastplates, spears, swords and daggers, some very curious in shape. On opening a stone vault, they found also some plate, including church utensils, such as a monstrance and a chalice, the workmanship of which is thought to be of the 14th century. On the base of the monstrance are engravings in old English characters the words "Ave verum corpus, natum de Maria Virgine, vere passum, immolatum in cruce pro homine." The uses of some smaller articles which have been discovered have yet to be ascertained.

An inspector of the Board of Trade has made an official examination of a new line of railway in East Kent, constructed by the South-Eastern Railway Company. It is a single line, ten miles in length, and extends from a junction at Appledore with the Ashford and Hastings branch to a point on the coast within 100 yards of Dungeness lighthouse, passing through Old Romney and Lydd. At present the line is to be used for carriage of agricultural produce and shingle, but it will probably form a link in a new route to Paris, via Haddock, Dungeness, and Le Tréport. Mr. Walker was the contractor, and the cost has been less than £7,000 per mile.

The Limerick county magistrates considered on Thursday last, charges made against Mr. Cox, county surveyor for the Western division, with reference to the mode in which relief works had been supervised and paid for in Lower Connello barony, during March and April, and after a prolonged investigation, unanimously agreed to a resolution declaring that Mr. Cox "had acted in the most culpable manner in signing certificates for payment of works in blank, and entrusting them to his clerk to fill, the county surveyor not having inspected those works."

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C. Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 6s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is ONE SHILLING FOR TWENTY WORDS, and Sixpence for every eighth word after. All Situation advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in serial advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33fr. 30c.). To India (via Brindisi), £1 10s. 10d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

Mr. CHARLES WILSON, of 13 and 15, Lighthouse-street, New York City, is authorised to receive American subscriptions at the rate of 6 dols. 40c. per annum.

Mr. R. M. TUTTLE, of Titusville, Penn., U.S.A., is also authorised to receive subscriptions at the same rate.

Cases for binding the half-yearly volumes, 2s. each.

NOTICE.

Now Ready.

Vol. XL. Price 12s. A few bound volumes of Vol. XXXIX. may still be had, price Twelve Shillings; all the other volumes are out of print. Most of the back numbers of former volumes are, however, to be had. Subscribers requiring any back numbers to complete vol. just ended should order at once, as many of them soon run out of print.

RECEIVED.—J. L. A.—T. M. I.—R. M. M.—T. B.—H. J. O.—F. and Co.—G. S.—J. C. H. and Co.—McG. and Co.—G. P. B.—C. and Son—G. H.—R. H. and Co.—B. S. B.—G. Y. U. S. A.—C. B.—R. B.—R. and E.—T. B. and Co.—J. J.—E. and G.—B. B. and B.—C. of C. O. and L.

CONSTANT READER. The system is good. Apply to the Sanitary Engineering Co., Victoria-street, S.W.

"BUILDING NEWS" DESIGNING CLUB.

DRAWINGS RECEIVED.—Good Luck to Your Fishing, Yarra Yarra, Bonus Hummus, Vignette, X L., Montague, Hamlet, Iota, Walter II., Rev. Jack, Pin-m R-spice, Nitor, Per. Will, Lancaster, Fiat, Ambition, Dornus.

ROBT. REEVE. (Our review of the designs places "Jack's" second in merit, and that opinion is to be taken in preference. "R. R." points out three defects in "Jack's" design, published: 1. the pantry door facing entrance, 2. no bead-room under stairs to enter w.c., 3. gable in front not in centre of window. We illustrated the design for its picturesque spirit.)

Correspondence.

SEWER-VENTILATION.

To the Editor of the BUILDING NEWS.

SIR,—I have read with great interest your report of Mr. Hellyer's lecture on "Traps and Trap Ventilation," and the description of the experiments which visibly demonstrated the possibility of an ordinary C-trap, under ordinary action, becoming unsiphonised.

It is common enough to hear a person say: "I would not have one of those abominable water-closets in my house," and most travellers are well aware that many w.c.'s are found to be extremely objectionable; this has hitherto been attributed to neglect or carelessness; but Mr. Hellyer's experiments go far to exonerate any person, and rather condemn the apparatus; they tend to prove that the C-trap is a danger, instead of a defender; a traitor instead of a treasure.

It is only reasonable to expect that the same orifice which, as is well known, so effectually destroys the action of a simple water siphon pipe, would be equally effective in restricting the siphonic action of a sewer siphon or C-trap, both have a long and a short leg, and in both cases, the smallest crack admitting or emitting the most minute medium of air is sufficient to unsiphonise the tube; hence the one thing necessary to insure the water seal is an opening at the apex of the outlet bend of the C-trap. It also appears consonant with common-sense that sewer-gas would readily and persistently ad-

vance up an open and unresistant ventilator pipe, however small it might be, rather than struggle and force its passage through the water seal of an effective unsiphonised trap. I have, during several years, extensively adopted a system of sewer ventilation, founded on these principles, viz., to every inlet of sewage a trap, and to every trap a *compo tube* at its exit bend, and although the sewer system terminates in a large cess-pool where sewer-gas must necessarily be engendered, yet these small $\frac{3}{4}$ tubes have proved thoroughly effective; they can be bent round spouting and other projections, so as to project the orifice well above the eaves, and sufficiently distant from any windows. I am compelled, therefore to conclude that all other expedients, such as fresh-air inlets, full-bore vent-cowls, and other patent complications are, at best, only superfluities.

I am inclined to object to Mr. Hellyer's wholesale condemnation of Mansergh's yard or sink trap. The ventilation is thoroughly secured by a $\frac{3}{4}$ in. ventilating pipe in the apex of the sewer trap. The fact that it is not self-cleansing is not altogether fatal; in many cases it is advisable that a yard trap should be also a collecting trap. There are matters, such as sand, gravel, &c., which it is proper to exclude from the sewers. Mansergh's trap would be improved if it was made larger, more simple, and more easy to be cleansed; the openings inside the body of trap are much confined, and thus interfere with a ready and effective clearing out of the detritus. —I am, &c., MICHAEL DRURY.

Lincoln, July 11.

A BI-CENTENARIAN C-TRAP.

SIR,—Knowing what interest you always take in matters of sanitary work, I herewith

forward you a photograph of an old lead C-trap which, although over 200 years in constant work, is in a very good state of preservation. There is something very remarkable about the make of this trap; the bottom near B is quite $\frac{3}{4}$ in. thick, whilst the other parts are only about $\frac{7}{16}$ lb. lead, showing at once that the old school of plumbers were alive to the fact that traps in those days often had their bottoms punched out. Hence the reason for the extra thickness. I may here mention that this trap was taken out of Southbury Old Church (Sir Christopher Wren, architect). —I am, &c.

P. J. DAVIES, H.M.A.S.P.

SANITARY PLUMBING AND PLUMBER'S WORK.

SIR,—I can understand Mr. Pullen's opposition (he being a manufacturer of the C-trap) to Mr. Hellyer's remarks on the advantages of the C-trap over the C-trap. But your correspondent, Mr. P. J. Davies (whom I greatly respect) I am at a loss to understand, when referring to the article written by him in your last week's issue. I know that Mr. D. has now for some time been advocating the use of the C in the place of the C-trap. But what does he mean in his concluding remarks upon the above subject, when he calls the attention of your

readers to the fact "that we Society plumbers have never disputed that the S trap has the best chance of clearing itself of any foreign substance, such as gravel, sand, &c." It is something new for him to own this, and I am quite surprised at it after reading and hearing his remarks in favour of the much illused O-trap. Now if the S-trap has this advantage over the O-trap with such heavy substances as he mentions, will it not be found still more advantageous and have a far greater chance to clear itself of such lighter substances that will more readily float, and which are intended and supposed to pass into these traps? Any object that partly floats must obtain the full force of the water that is brought to bear upon surface of the dip or inlet side of the trap, and if it will clear itself of sand, &c., it must of a necessity clear itself of soil with a reasonable supply of water; which cannot be said of the O-trap.

I beg to differ from the opinion that the O-trap has the advantage claimed by Mr. Davies, "that it allows the soil to pass to the other side of the trap, &c.": for this rarely occurs with the O-trap unless there should be a good flush of water to force it to the other side, and then it often happens that a part of the soil is left behind in the O-trap, even with a reasonable supply of water. But Mr. Davies does not state the case fairly when speaking of the small-size S-traps having cleansing caps and screws. Haven't small O-traps these screws, and which are more frequently opened? I say the O-trap. Then in both cases it is on account of the inlet being much smaller than the body of the trap, for it rarely happens that these caps are removed where the inlet is about or slightly over the size of the bore of the trap. In fact, it is only in such cases mentioned in connection with lavatory basin washer and plug, &c.

Mr. Davies, I regret to say, is most unfair in some of his remarks relating to Mr. Hellyer, and I am sorry to see a man of Mr. D.'s experience and abilities taking such a wide view of these lectures which, without doubt, are likely to do much good, even to the present class of plumbers. For Mr. Hellyer, I believe, is the first man who has dared to speak to us from a public platform, and the more thanks are due to him for his endeavours, even if he does go too far.

I do not believe in all Mr. Hellyer puts forward from the platform, neither do I advocate the use of his siphon traps, which are certainly constructed wrong, for I believe that the hand or block-made S or half O-traps are far superior to the siphon or O-trap, and are not nearly so liable to wave out, or siphon, as Mr. H.'s patent trap, and considering how cheap they can be made by the proper men, I am surprised that they are not more in use. If Mr. D. or his friends who oppose Mr. H. think that the O-trap possesses advantages which the S-trap does not, why not state them and prove it by severe tests by the side of a blocked or hand-made half S trap. It will be a surprise to me if they can prove anything in favour of their pet trap, excepting that the O-trap is liable to siphon, which is a good fault in a trap, and which, as you know, is easily prevented.

I was greatly disappointed at many parts of Mr. Hellyer's theory, and wish he was more practical; but hope that others well able to keep the light burning will take the subject up, and let us see both sides of the question. I am, &c., Lambeth, July 11. H. B.

BUILDING-STONES.

Sir,—I have been amused with Mr. Masey's strong advocacy of Beer-stone in your columns, to the utter disregard of the merits of many other building-stones; and seeing that he has already been corrected, he does not appear to be a judge of the different kinds of stone when he sees them, and I would recommend the public to verify what he calls "stubborn facts which cannot be explained away" before they take them for granted. What he speaks of at Buckingham Palace as prime Bath-stone is in reality printed Caen. A for man of mine on whose word I can implicitly rely, assures me that he worked through the jobs when the stone was used. Has Mr. Masey fallen into the same error with reference to the house he refers to at Kensington? Kensington being a large locality, he does not give the public a chance to judge for themselves by stating the size of the building. The "ordinary Bath-stone" mentioned was probably badly chosen for the purpose used, as

I certainly very much doubt that good "Box-ground" can have failed, as he states. My experience of "Box-ground" in Bristol is that it is a splendid weather stone. Mr. Masey, I should imagine, was of the same opinion at one time, as I know he specified "Box Ground" for the exterior of St. George's Parish-church, Bristol, when it was reinstated after injury by fire in the early part of 1879. I have used a great deal of "Box-ground" in my time, and all I can say is that if "Box-ground" was used for the exterior of that building, I never saw any in my life. Of this I am positive, and any one can see for themselves by inspecting it. So much for Mr. Masey's judgment of the quality of stone. I am pleased to see the building is in a good state of preservation, but what I mean is that Mr. Masey did not get what he specified. I am afraid one stone being used where another is specified leads to confusion and discredit to meritorious stones. If your correspondent, "Durability," and Mr. Masey would like to see a few instances in which "Box-ground" has successfully withstood the decomposing influences of a densely-populated city, abounding in chemical works, with an atmosphere highly charged with noxious gases, and which is also open to the severity of the Bristol Channel gales, I would recommend him to inspect the West of England Bank (elaborate architecture crowded with sculptured Box-ground), the National Provincial Bank, Wilts and Dorset Bank, London, Liverpool, and Globe Insurance Buildings:—this latter abounds with fine mouldings, elaborately and delicately carved, and statuary throughout, all Box-ground. St. Stephen's Church, the tower of which is the highest in the city, and, consequently, very exposed, is a splendid specimen of Box-ground; it is the richest work of the kind I have seen. All these buildings will be found in an excellent state of preservation.

It is evident that all the kinds of Bath stone harden more or less by exposure as the stone dries. I have often particularly noticed this in the case with Box-ground in the largest and most important buildings in this city. A hard lining is formed on the surface, which, to all appearance, is a sure safeguard against weather. —I am, &c.,

A BRISTOL BUILDER.

Sir,—"Durability" says that "of all the Bath oolites the Box-ground is most affected by the steady action of a south-west exposure to severe storms, a damp climate, or a chemically affected atmosphere." Now, as this controversy has arisen out of Mr. Pearson's proposal to use Bath-stone for Truro Cathedral, and Truro being a quiet market-town without manufactories, the question of a "chemically affected atmosphere" does not apply; but as "Durability" referred to Cornwall, Cornishmen, and Cornish stone, he ought to know at least that we have "a south-west exposure to severe storms, and a damp climate." We are too much exposed on high ground on the verge of the wild Atlantic to escape any storm when Nature puts on her angry mood; and when the vapoury clouds sweep up from the ocean they are sure to break in copious showers on our Cornish hills. And what is our experience of Bath-stone? The mansion at Trehidy has been referred to. It is built mostly of Bath-stone. There the Box-ground used many years ago is as perfect as when erected; but the Corsham stone, used in additions of a later date, are going to pieces with successive frosts. Now mark what "Durability" says—viz., that "Corsham stone is the most lasting." When the Corsham people want a good weather stone for an exposed position, they do not use Corsham stone, but go some miles away for Box-ground!

The statements of "Durability" about Bath-stone are on a par with his knowledge of Cornish stone. He wants Mr. Pearson to use "the materials readiest to hand," and appeals to him in turns by flattery and persuasion, invoking the names of the Holy Catholic Church and the Diety! and, of course, he does not forget to quote Scripture. Does "Durability" know that the old builders used "materials readiest to hand" in St. Mary's Church, Truro—viz., alvan of various sorts and St. Stephen's granite, and Bath-stone, and that Bath-stone has stood for centuries more perfectly than either? The Bath-stone in the old church being somewhat coarse in grain, is, I think, either Combe-down or Box-

ground. The St. Stephen's granite and alvan have gone to pieces where exposed.

After the pathetic and religious appeal of "Durability" for the use of "materials readiest to hand," he at once suggests that we should take ship and sail away to France for Caen stone!

But the climax of the suggestions of "Durability" are not reached until, quoting Scripture, he urges Mr. Pearson to set aside his plans, pull down the work inaugurated by the Prince of Wales, and commence afresh, in order that he may use granite in a simpler form than already described. I presume he means hard granite. It would, of course, be impossible to use hard granite with the means at Mr. Pearson's disposal. To build the cathedral in hard granite would cost £250,000 at least, and so far there is only £40,000 in hand. This stone, says "Durability," is "admirably expressive of the steady, preserving character of Cornishmen, and characteristic of the ruggedness of their country." Indeed! "Durability" will find that however "rugged" we are determined, with Mr. Pearson's aid, to have a cathedral that shall be well worthy of the age, and, to quote the architect's words, "a building in which men shall be compelled to fall down and pray." There is, alas, a spirit of rivalry and jealousy caused by the cathedral and the re-creation of the Cornish Diocese, and it is only too evident that, should the building scheme collapse, it would be hailed with shouts of fiendish delight. But it is not the habit of Cornishmen to play see-saw over their great undertakings, and while secret attacks, however well concealed, continue to be made, Mr. Pearson and his co-workers will not want defenders.—I am, &c.,

JAMES HICKS.

Redruth, 12th July.

Sir,—We do not desire to trespass upon your valuable space, especially upon the subject of stone of which we are the vendors, but must in self-defence, in reply to "Durability," reiterate our former statement, that Box-ground "is a weather stone of great merit and undoubted repute, for durability in the most trying situation." By this it will be seen that we did not and do not overlook the point raised, nor did we intend to convey the limited construction put upon our statement by "Durability." We are pleased to note he concedes it to be a weather stone possessing ability to stand frost. What we mean by "trying situations" include positions in which the buildings would be exposed to the action of south-west or other storms, a damp climate, or a chemically-affected atmosphere. There are hundreds of instances in which "Box-ground" has satisfactorily stood such tests, on the west and south-west coasts, and in the largest towns all over England. An inspection of these buildings would certainly show that the case-hardening process is a distinctive characteristic of "Box-ground," and this fact alone has been the means of greatly extending its use in trying situations. We have found in many cases which have been quoted as proofs to the contrary, that the material was not the kind stated, and in others to have been badly selected, or badly laid. We regret to say that much of the prejudice created against Bath stone has arisen from an improper use of the different kinds for the purposes for which they are naturally adapted: in many instances, one kind being specified and another used, in consequence of the inadequate knowledge of those connected with the buildings. With all respect to "Durability"—whom we doubt not, writes in good faith—we cannot help thinking the instances which have come before his notice must have been where the kind of stone has been badly selected or unfairly used.—We are, &c.,

Box, July 12.

PICCOL AND SONS.

Sir,—My experience of Box-ground, since 1814, is that when well selected and properly used it is one of the best weather stones in the kingdom. What I mean by proper use is, not, as most architects think, that the stone should always be used on its natural bed, for I know for some purposes there are better ways for its use. I could so use Box-ground in almost any position as to vie with any other stone that can be found for building purposes.

I fear that some of the more economical kinds of Bath stone, under the name of "Box-ground" will not stand the London atmosphere. My experience being a London one, I venture

to quote the following buildings, where Box-ground was used and which are still in a good state of preservation.

Inns of Court Hotel, Holborn; Mansions, Victoria-street, "Station End;" extensive buildings for Vickers' distillery, Victoria-street. Kensington parish-church, Lancaster Gate; All Saint's church, Talbot-road, Bayswater; St. Stephen's church and St. Luke's church, Westbourne-park. Chambers: Basinghall-street, City Temple. Large shops: east-end of Holborn Viaduct, opposite St. Sepulchre's; St. Augustine's, Kilburn; St. Jude's, Kensington, and St. Augustine's, South Kensington.—I am, &c.,
PRACTICAL.

QUANTITIES.

SIR,—I beg to inclose (for publication if you see fit) a copy of a letter recently sent by me to Lord Coleridge, who informed me that he had read it "with interest and attention."—I am, &c.,
WILLIAM SIMMONS.

161, Friar-street, Reading,
July 6, 1881.

MY LORD,—In the *Times* report of the recent trial of Evans v. Carte, your Lordship is reported to have said "that (apart from actual contract) it is quite monstrous that the employer should pay for the 'quantities'; that is, that he should pay for what it is the duty of the architect to do. The builders are to make their tenders upon the plans; but, before they do so, they must know the quantities they represent. Why should the architect's employer pay for them?"

My Lord, having an interest in seeing justice done and misapprehension remedied, I will endeavour to explain to you why. The employer should pay for the work because it is done in his service, and is not covered by the 5 per cent. which is the customary payment of an architect for his proper services as such, and which was so, long ere quantities were supplied at all, when tendering was largely a matter of guesswork. It is simply a question of agreement: and where there is no express agreement, the equitable thing is to follow the custom of the country.

Let us take a hypothetical case. Your Lordship goes, we will assume, to Mr. Street, to design you a house and superintend the erection of it by contract, and agrees to pay him the usual percentage for so doing. For this purpose, Mr. Street makes certain laboriously worked-out geometrical drawings, correct to scale, and with all the dimensions figured on them, and the differences of the materials shown by differences of colour, thus accurately delineating the house in every part. He also writes an equally-laboured specification, explaining the drawings, and accurately describing the nature of the materials and workmanship, the times and manner in which the work is to be done, and giving whatever other directions may be necessary. These drawings and specification contain all the information required for the erection and completion of the house. Mr. Street accordingly lays them before a number of builders with a view to procure tenders from them, it being understood that the one who tenders lowest will get the job. Now, before the builders can give tenders, they must each make an estimate, and, to do this, each must "take off the quantities" as the first step; that is, he must calculate, as nearly as human fallibility can, the amounts of material and labour which he will have to use and pay for in building your house as drawn and specified by Mr. Street. After he has made these calculations, he prices out the items according to the current rates for work and material, and the percentage of profit he intends to get.

This reads very smoothly, and if taking off the quantities were a mere matter of hours each builder would do the work for himself and pocket the slight loss of time if he failed to get the job. But, as a matter of fact, the quantity-taking is a very laborious process, and demands great experience, and also involves very considerable expense in assistance, &c. Therefore, these builders who are ambitious of the profit (I fear they would hardly think of the honour) of building a house for your lordship, agree among themselves to employ an experienced quantity-surveyor (and, as Mr. Street himself, unlike many architects, is not a quantity-surveyor, they cannot employ him, but must select some one else) to do the work for

them, on the mutual understanding that the successful tenderer should pay for it at the rate of 2½ per cent. on the amount of his tender. Each builder, therefore, includes that amount in his tender, adding it at the end of his other calculations, and thus it ultimately comes out of your own pocket as employer.

But suppose that, after you have approved of the designs and instructed your architect to ask for tenders, you alter your mind and decide not to build the house, although the quantities have been taken off—how, then, my Lord, who is to pay the surveyor's bill? Not the architect, surely, for the work in question has nothing to do with his proper services to you as architect of your house. Not the builders who gave you tenders; for though the surveyor is their employé and they collectively ordered the work and agreed that one of them should pay for it, still they only did so as your servants, and the money to pay for it was to have come out of your pocket. But you have not fulfilled your (actual or implied) agreement with them and the funds are not forthcoming. By asking for tenders you entailed this work on the builders, and now you leave them in the lurch. Surely, my Lord, justice and common-sense agree that you must pay for that quantity-work, you having gone back from your promise to the builders, under which promise (namely that you would accept the lowest of their tenders) they ordered the work. Were it to be decided otherwise, and the builders to be held liable, the whole trade would (very naturally) at once strike work on such terms, and insist on being in each case specially exempted from any such risk before they would tender at all. Or, again; if, still more absurdly, Mr. Street were held liable, and made to pay for this work out of his fees received for other services, and which were the usual payment of those services long before quantity-taking was done with any care, and while tendering was still very much a leap in the dark, or the work was paid for on a charge sent in after it was done, then the only effect would be that architects throughout the country would increase their charges by the amount of two and a half per cent. and insist on having a legal guarantee for that increased amount from each employer before they began work.

Well, my Lord, the account I have given you above represents accurately what takes place with regard to quantities for any building, except only that, in practice, because it would not do to have the builders lay their heads together and tender by common consent, so that one of them should secure your job at greatly over the value, and pay the others for tendering above him, they are not called together and introduced to each other as competitors, and invited to appoint their quantity surveyor; but the latter is nominated by the architect (or yourself if you will meddle in a matter of which you cannot be expected to know anything), and each builder, without knowing who are his competitors, accepts this surveyor's work and agrees to pay for it in case you accept his tender and pay him. This plan still further increases your moral liability for the quantities in case of abandonment of the design, and ought to make you legally liable *directly* to the surveyor, instead of indirectly through the builders, with whom you have, as it were, broken faith.

There is one other point which it may be desirable to clear up. If, in the course of this laborious process of quantity-taking (and your Lordship would be surprised to find how laborious and tedious it is) it should happen, as with even the most careful and experienced surveyors it now and then does, that some of the material or labour gets overlooked or omitted from the quantities and estimates (tenders) based on them, it is evident that every tender will be so much the lower, and that if the selected builder is to be made to carry out the building, as drawn and specified, for the tendered amount, he will suffer a loss, and you will have got a portion of your building presented to you *gratis*; and this you will still do even though the builder should recover his loss from the unfortunate surveyor, who, at most, ought only to be liable to a fine. Therefore, to make the matter square on all sides, it is growing more and more the practice to "make the quantities a part of the contract"—that is, to agree that the contractor shall only be held liable to execute under his contract the works actually included in the quantities on which his ten-

der was based, and that you, the employer, should pay the additional value of any work thence omitted, even though shown and described, or implied, in the contract drawings and specifications; while, on the other hand, if too much work has been taken in the quantities, you are entitled, on the discovery of the excess by your architect during the progress of the works, to have the value deducted. Of course, if the surveyor has been careless or incompetent, and has utterly misled you as to the cost of the house, you have your remedy against him in the usual way, and can punish his fault, though not profit by it or by his misfortune.

Pardon my saying a word with regard to another disputed matter about which I am not sure if your Lordship has yet had to decide. I mean with regard to ownership of drawings from which a building has been erected. These are usually retained by the architect as owner of the copyright, but cases have occurred in which the employer has claimed them. A former Chief Justice, giving judgment in one such dispute, said "Why should not a man have what he has paid for?" and to that question there can be no reply but "Why, indeed!" Only the fact is, that the employer cannot justly be held to have paid for the architect's drawing further than as they concern the building of his house. Having the house, he has what he paid for. The design and superintendence are that for which he pays the architect, and the drawings are merely means which the latter uses to convey his ideas. I reply, then, to the former Chief Justice, "Why should a man, having what he has paid for, have also what he has not paid for?" Having got, for instance, the lithographed copies which you ordered, do you expect to get the lithographer's stone into the bargain? or, having bought a book, do you consider you have paid for the author's manuscript?"

Apologising for the length of my letter (which ought to need no apology having justice as its aim),—I am, your Lordship's obedient servant,
WM. SIMMONS.

161, Friar-street, Reading, June, 1881.
The Lord Chief Justice of England.

WINDERMERE CHURCH COMPETITION.

SIR,—Your correspondents of last week are not the only competitors who have been treated with "silent contempt." But perhaps they are not aware that the successful architect is the son of the principal builder in Windermere, which may perhaps account for the silence of the committee.—I am &c.,

ANOTHER OF THE FOOLISH.

TENDERS—A CORRECTION.

SIR,—In your edition of Friday last, under Tenders, you publish under Dartmoor, construction of reservoir at Kennick, Mr. Little surveyor; Kraus, contractor; amount about £3,000. This is all incorrect.

I beg to say the engineer is Mr. H. M. Brunel, C.E., of 23, Delahay-street, Westminster, and the amount of my contract is £9,440. I will thank you to correct same in your next.—I am, &c.,
A. KRAUS.

Colston-street, Bristol, July 13.

INSIGNIFICANT TENDERS.

SIR,—The following surely deserves a little notice, as showing how far the mania for competition may go.—I am, &c.

Newcastle-on-Tyne.

G. C.

TWO JOINERS AND OTHERS.—The Long Benton School Board is prepared to receive TENDERS for the following WORK at the Walker West (Mixed) School, viz.:—Alterations to Raised Platform, lengthening same by about 31 feet. A platform now in the school may be used in the work. Three D.sks, 8 feet in length, with forms, will be required to be made and fixed to the platform. The Mistress's Desk, with part of the Cupboard, to be removed; both parts of the cupboards will require new sills.—For further particulars apply to the Head Teacher at the School's. Tenders to be sent to the Clerk, T. M. STONESS, 31, Clifftonwood street, Newcastle-on-Tyne, not later than Saturday, the 16th inst.

ABBOTT'S HOSPITAL, GUILDFORD.

SIR,—While pleased to see your illustration of the hospital in High-street, Guildford, published in your Midsummer Double Number, I, as an old scholar of Abbott's School, attached thereto, must take exception to the definite article being prefixed to the title.

Upon this point we were always very particular, lest the credit for the "foundation" due to the famous Guildfordian named Abbott should be attributed to the religious order of old. It should

be simply Abbott's Hospital, as your description explains, not "The Abbott's."

May I further add, the building some years ago underwent a faithful and complete restoration externally, consequent upon the decayed state of the brickwork? Most, if not all, the old chimney stacks were then rebuilt, so that the existing work must not be looked upon as altogether original.—I am, &c., J. WILLIAM STEVENS.

6, Southampton-buildings, W.C., July 7.

CHIPS.

Last week a two-light stained-glass window was placed in the west end of north aisle at Halifax parish-church, as a memorial to officers of the 33rd Regiment killed by a landslip in India. Messrs. Powell Brothers, of Leeds and Whitefriars, London, were the artists.

The Marianne-Norington memorial drinking-fountain on the Hoe, Plymouth, was formally presented to the town on Wednesday week. It is built of Portland stone and red Mall granite, and is surmounted by a figure in the former material of "Rebecca at the Well." Messrs. Hine and Odgers, of Plymouth, were the architects. Messrs. Freeman and Sons, of Penryn, executed the work, the sculptor being Mr. Samuel Trevenen, of Plymouth.

The completion of the new waterworks at Granton, N.B., was celebrated on Saturday by publicly turning on the water in the town. The supply is obtained from springs at Fauran, Alnham, at an elevation of 275 ft. above the square, and discharges 68 gallons of water per minute, equal to 62 gallons per head supplied per day. The contractor was Mr. W. Scott, of Calderhill, Inverness.

A memorial three-light window to the late Mr. J. T. Armitage was unveiled in Almondsbury parish church, near Huddersfield, last week. It is on the south side of nave, and has as subjects, in the centre, Christ, the Light of the World, from Holman Hunt's picture; and in the side-light, the Virgin Mother and the Apostle John. Messrs. Heaton, Butler, and Bayne, of Garrick-street, London, have carried out the work.

At a meeting of the Beverley and Barnston drainage commissioners held on the 30th ult., the plans of Mr. Barry, C.E., for the drainage of the district were, after a long discussion, adopted and ordered to be carried out as speedily as possible. The estimated cost is £25,000.

The tender of Messrs. William Cowlin and Son has been accepted for the erection of the Church of St. Saviour, Woolley Park, Bristol, at £1,839, this sum to include the whole of the work except carving. Mr. J. Bevan, of Nicholas-street, Bristol, is the architect.

The new waterworks for Forfar are in course of completion, and it is expected that the service reservoir at Paggerton will come into use in three months' time, and the principal one—that at Den of Ogil—before Christmas. The chief engineer is Mr. J. Bateman, C.E., of London who paid a visit of inspection to the works last Friday.

The pier at R-dear, in the North R ding, which was cut through by a brig during a storm last October, has just been restored, and was reopened on Saturday. The work of rebuilding the six bays demolished has been carried out under contract by Messrs. Heald and Wrighton, of Stockton-on-Tees.

Mr. Yeo has been appointed surveyor to the Okehampton rural sanitary authority.

Extensive railway improvements have just been commenced at South Stockton by the North Eastern Railway Company, the scheme including the substitution of a new island station for the present inadequate one, the alteration of all level crossings, and the construction of a new railway bridge across the Tees. The contract has been taken by Mr. Walter Scott.

An inquiry was held at Sidmouth on Friday, before Mr. Arnold Taylor, one of the inspectors of the Local Government Board, on an application of the Sidmouth local board for sanction to borrow £1,000 for works of sewerage and street improvement.

The restoration of the parish-church of Rye, Sussex, has been commenced this week.

On Saturday, Captain Hobbard, R.E., on behalf of the Local Government Board, held an inquiry at Oswestry, with regard to proposed loans by the town council of £2,000 for street improvements and £100 for sewerage works. On the same afternoon the members of the town council visited alternative sites at Penegwely for the proposed new reservoir suggested by the water-engineer, Mr. Edward Filmer, C.E., of Leeds.

The guardians of Carlisle union have adopted plans by Messrs. Hetherington and Oliver, of Carlisle, for alterations at Fashill workhouse.

Entercommunication.

QUESTIONS.

[6531].—**Disputed Contract.**—Will Mr. Hugh Melchian, whose lucid replies so frequently assist us, advise me on the following?—A carpenter, having furnished plans and specifications, and become competitor for the contract, another party got the contract at a considerably less sum, and the carpenter got the appointment of clerk of works over the contractor. Now, when the contractor says the works are finished, the clerk of works brings forward a list of charges, some for works omitted to be done, others not done in accordance with the specification—walls lower than shown on the plan, the contractor insisting they are just to the height personally ordered, and that when the scaffolding was up and men going on a few inches (the difference only) either was or very small consequence to him. The most difficult to deal with is a "concrete" floor. In the specification there is no instance on us to how it is to be made. The only mention in the specification that could possibly be applied to it is on the first page of what he calls general conditions in the expression "Cement where used to be of the best quality Portland, made in the proportions of two parts sand to one of cement," and on the second page of general specification, "The floor of same shed to be of concrete at least 2 in. thick." The ground on which his floor is formed is soft and damp. The ground on which the floor was formed to which my specification was applied is hard and firm, somewhat gravelly, yet 9 in. deep of stone, closely packed in two courses by hand, and after this 4 in. deep of broken limestone, tightly rammed to a straight edge. Concrete formed of sifted gravel and sifted sand edge, thoroughly washed in finer sieves in two waters, 3 parts gravel and 1 part sand to 1 part cement, all by measure, mixed freely in a dry state, and tempered on a stage, spread by a wooden float, punning down the composition fully 1 1/2 in. among the stones, and to be 1 in. above the stones. I don't believe, no matter if the composition were unusually strong, it could withstand the "wear and tear" it must endure in a public market-yard in the absence of such a foundation as stated above, to secure drainage and firmness. In this case, if the proportions required by the specification were observed, the cement must have been dead or adulterated before being used, or it must have perished since, as the composition has become quite disintegrated. By the foot it can be easily rubbed into dust—as a floor it is perfectly useless. All the parties concerned have agreed among themselves to leave the entire matter to my award. My own opinion is that it would seem to be unreasonable to hold the contractor responsible in the absence of a proper specification for a properly-made floor, but for the value of the cement and sand expressed in the specification and laid in position—say, 2s. 2d. per yard. But it seems to me a most anomalous action of a clerk of works to have permitted bad materials, wrong proportions, and objectionable workmanship in the works to have accumulated till the job is said to be finished, instead of, as they occurred, to have them remedied, by removing the objectionable materials and work, or if the contractor became refractory, suspend the works till this was done.—J. McD.

[6535].—**Smoky Chimney.**—Can any of your readers kindly suggest a method of preventing smoky chimneys in third-floor offices in the City of London? The water would prefer something cheap, simple, and effective.—DOWNSIDE.

[6536].—**Excavation.**—How is circular excavation, as for wells, measured, and what are the dimensions taken?—X. Y. Z.

[6537].—**Bosses and Dogs.**—What is the meaning of the term "bosses" as used in plumbing? Also, what are the iron dogs of a door?—X. Y. Z.

[6538].—**Measuring Buildings.**—What is the best method of measuring up plans, sections, &c., of old buildings, such as churches? Is it necessary to have board and squares on the spot, or is a book sufficient, into which dimensions are taken to be plotted at home? Any information on the subject, or the name of any book, will oblige.—STUDENT.

[6539].—**Reservoir.**—Short description of the following will oblige. Suitable reservoir (material, size, filter, and pipe connections) for keeping constant supply of water to a country house of, say, twenty inmates, and also to supply stable, &c. There is an unlimited supply of water from a stream, which, however, is very liable to be fouled by clay when in flood. As it is desired to dispense with cisterns in house, what is the best arrangement for not wholly cutting off water when reservoir is being cleaned?—L. L. U.

[6540].—**Local Board Office.**—Could any of your readers inform me of a well-designed local board office, comprising board room, usual offices for tax collector and surveyor, suitable for a population of, say, 5,000? As I have similar offices to design, I should be glad to learn of any well-proportioned building of that class.—BRUNING SURVEYOR.

[6541].—**A Difficulty.**—An architect leaves a set of quantities, desiring a tender for the work. The estimate is sent, but before it is settled who is to have the contract, the gentleman calls and asks that the priced bill of quantities be given up. Upon our refusal to do so before our tender is accepted, we never refuse after the contract is settled; he withdraws, places the work elsewhere, and assigns as the sole reason the non-compliance with his request.—SWAN.

[6542].—**Diagrams.**—I have to prepare a number of large diagrams illustrating various features of architectural construction for a course of lectures on that subject. It is necessary that they be prepared in such a way that they may be folded without injury in order that they may be carried from place to place. Will some correspondent be good enough to give me some information as to the material and colours I ought to use? Any hints will be acceptable.—A. J.

[6543].—**Damp Wall.**—I am connected with a Sunday School library, and the wall at the back of the book-case is an external one, which is very damp. I should be very glad if some of your readers would give me their opinions

of the best method of coating the wall, internally only, so as to prevent the damp coming through. If paint, or any glutinous mixture should be recommended, I should be glad to know what ingredients would be required, quantity to use, and probable cost per superficial foot.—LABRARIAN.

[6574].—**Ventilating Drains.**—The by-laws of the municipal sanitary board here, give us the system to be adopted of ventilating drains as sketch, and specify the

cesspool to be also ventilated; whereas our sanitary surveyor requires the air chamber in position dotted and marked A.C. and further states that the cesspool will be sufficiently ventilated without supplying a separate ventilating drain for it. As the surveyor and the by-laws seem to give exactly opposite opinions, I should be glad to know which is right, if either? And, moreover, the by-laws say that the ventilating shaft shall contain a sectional area not less than that of the drain it ventilates; whereas ninety-nine out of a hundred here are from 2 in. to 3 in. diameter to ventilate 6 in. drains; and this with the entire sanction of the surveyor. I should like also to know if a plan is passed and signed by the board, whether the surveyor can compel you to do things at variance to such plans.—COUNTRY SUBSCRIBER.

REPLIES.

[6531].—**Bridlington.**—The following notes may, perhaps, be of some use to "E.C." during his visit to Bridlington and Scarborough:—Flamborough, 4 miles from Bridlington, is, of course, interesting to any one on account of its natural attributes, and the church there is well worthy a visit. It contains a Norman in-chancel arch and an old wood screen (very rich of 15th century work). Burton Agnes, 4 miles from Bridlington. Here there is a good church, and the hall is a fine and rare Elizabethan mansion said to be designed by Inigo Jones. It has a rich entrance gateway of the same date, above the centre arch of which are the Royal arms of James I. Hunmanby Church was the "Matrix Ecclesie" of several others in the neighbourhood. It is old, good, and interesting. There is a quaint oak roof, and in the chancel is a fine marble monument (figure of piety by Fisher) to the Oshaldston family. The hall lodge is a pretty curiosity, having been erected in 1829 to represent a monastic ruin. The stone was obtained from Filey Brigg, and was thoroughly weather beaten by the action of the sea before its removal. There is also a good stone high gate, recently erected to the memory of the late Admiral Milford, R.N. Also Rudstam Church is good, and there is the celebrated stone obelisk in the churchyard. It stands over 25 ft. above the ground (probably as many below), and has been calculated to weigh upwards of 50 tons.—HENRY LAWSON.

[6552].—**Thickness of Piers of Arches.**—It would appear that Gwilt's method for finding the thicknesses of abutments or piers to arches is either not to be trusted or fails to convey the true meaning. Further, that the formula or geometrical method usually given do not agree with each other in their results, thereby leading to an uncertainty in the minds of all who have not a thorough acquaintance with the subject, and I am afraid not one such is to be found. It is necessary in order to understand modern theories on the arch to know integral calculus and higher mathematics. I have consulted the works of several authorities and calculated the required abutment thicknesses for the two examples of arches given by "J. H. M." with the following results. For the semicircular arch of 60 ft. span, supposing the height from ground to springing to be 30 ft.:—According to Gwilt's geometrical method, 7 ft. 6 in.; Tarn's method allowing half as much again for safety according to article in the Building News of Aug. 21, 1874, p. 218, partly geometrical and partly by quadratic equations, 8 ft. 4 in.; formula in Horst's Handboek, 10 ft. 7 in.; and the formula in Molesworth's Handbook, 13 ft. 8 in. For the segmental panted arch, of same span and height of abutments as the former, struck with a radius of 45 ft., the centres being 35 ft. below the springing:—According to Gwilt about 3 ft. 9 in. only; to Tarn's method, 10 ft. 10 in.; to Horst, 8 ft. 4 in.; and to Molesworth, 23 ft. 10 in. The reason why the results according to Molesworth are so much higher I believe that in that case the arch is supposed to be fully loaded with material of a nature homogeneous with that of the arch and abutments, whilst in all the other cases the arch is supposed to be loaded with its own weight only. Gwilt does not consider a loaded arch, Molesworth does not consider one unloaded, but Tarn and Horst provide for all cases; I prefer the latter. The formula in Molesworth is also given by Horst who adds, "this formula gives the thickness of abutment without wind or other forces just sufficient to balance the thrust of the half arch," the other calculated results are for the load only. In the Building News of Sept. 24, 1875, in an article on "The Stability of Arches" it is rightly pointed out "that it is customary to consider the arching as such a mass, besides its own weight, that of the entire superstructure raised over it" and "that this view is an erroneous one," further that a large portion of the superstructure is self-sustaining or is supported as if by a keel. The author is, however, I think, mistaken when he takes as granted, that the weight sustained "on the abutment" must have a resultant at right angles to the skewback. We are also told in the Building News, Dec. 17, 1875, on the authority of Dr. Hermann Schlicher "that the line" (curve of pressure) "may pass outside this middle third" (of the arch ring or face) "and generally so passes without endangering the arch's stability"; further "that an arch

cannot stand unless the line of pressures pass within the arch ring is disproved by experiment." It is thus seen that the present theory of the arch rests on an uncertain basis. I forgot to say when speaking of the two cases given by "J. H. M." that Hurst as well as Gaitt makes the unloaded segmental pointed arch require a smaller abutment than the semi-circular arch; this would in all probability, be found correct, but when fully loaded, the semi-circular arch would require the smaller. In fact a semi-circular arch of large span would not stand by itself, unless loaded on the abutments and extrados to the height between springing and crown; neither do the springings of such an arch carry the superstructure in the manner of an arch, but in the manner of corbelling, and the lowest joints might be laid horizontally, as was always done in the springing of groin ribs and often in the arches of arcades during the 13th century, care being taken to provide again the chipping of the feather-edges of the beds. Many readers would probably be surprised by my saying that a semi-circular arch is simply a segmental arch of smaller span, the total width being reduced by corbelling. The following extracts from Rankine's "Manual of Civil Engineering" will prove useful:—"Each pier of a series of arches ought to have sufficient stability to resist the thrust which acts upon it, when one only of the arches which spring from it is loaded with a travelling load. That thrust may be roughly computed by multiplying the travelling load per lineal foot by the radius of curvature of the intrados at its crown in feet." "Each pier of the arch should always give sufficient space on its top for two arches to spring from." "Either of these rules gives in general a less thickness than those adopted for piers in practice, which range from one-tenth to one-fourth of the span of the arches; the latter thickness and those approaching to it, being suitable for abutment piers. The most common thickness, for ordinary piers, is from one-sixth to one-seventh of the span of arches." "Piers, like abutments, are advantageously lightened, especially when very lofty, as in viaducts, by being built hollow, or by having archways traversing them, with inverted arches at the base." In a previous clause, he says:—"In some of the best examples of bridges, the thickness of the abutments ranges from one-third to one-fifth of the radius of curvature at its crown." M. Villette-Duc says on this subject in his "Dictionary of Architecture":—"To ascertain these actions by calculations would be a work of pure loss, for these calculations would vary in infinitude, on account of the heights or breadths of the openings, of the thickness of the solids, of the quality of the materials, of their resistance, of the heights of the beds, &c. But human sentiment, when hurried, is more subtle than calculation; in the same manner that a machine, however perfect it is, cannot attain the delicacy of the hand, and the surety of an eye glance." He had previously explained that the Early Medieval architects probably endeavoured to ascertain the thrusts of arches by geometrical diagrams, similar to though simpler than that given by Gaitt. Also read BUILDING NEWS, Feb. 4, 1876, p. 115.—HUGH MCLACHLAN.

[6560].—**Bearing Loads.**—For angle and channel iron, the breaking weight in tons per sectional inch has been given in one formula as $W = \frac{19}{1 + \frac{r^2}{900}}$, where $W =$

breaking load, $r =$ length divided by least diameter. The safe load may be taken as one length of this. Hurst's "Architectural Handbook" gives a formula.—G. H. G.

[6562].—**Defective Rain-Water Tank.**—As "User" does not want to dig round tank on the outside, nor to use asphalt, the only sure alternative I can think of is to build another brick tank within the present setting rendering the brickwork in cement. Let the bricks be impermeable, and the Portland cement of good quality.—G. H. H.

[6563].—**Durer's Works.**—On looking over my bound volumes of the BUILDING NEWS for the past ten years, I have found up the following reproductions of engravings or paintings by Albrecht Dürer:—The Virgin and Butterfly, published Jan. 20, 1871; the Apocalypse series, Nov. 7, 1873, and June 30, Aug. 4, Sept. 29, and Dec. 22, 1876. The Nativity, Dec. 24, 1880. Bits from pictures, May 2, 1873. Outlines from paintings, by Dr. Zentli, Aug. 24 and Sept. 22, 1876. Designs for decorations, April 25, 1879. Durer's house at Nuremberg was illustrated in the BUILDING NEWS for Dec. 24, 1875. Accompanying the illustrations on Aug. 24, 1876, is a biographical sketch by Dr. G. G. Zentli, to which I would refer "G. W. T."—EAST ANGLIAN.

CHIPS.

The annual excursion of the Cambrian Archaeological Society will be held at Ludlow and Church Stretton, during the first week in August.

The foundation-stone of a new block of business premises, now in course of erection for Messrs. Rowntree and Sons, at Westborough, Scarborough, was laid on the 7th inst. Mr. Burgess is the architect; Mr. George Scates, the contractor; and Mr. J. Kay, the clerk of works.

A tramway extension from Portsmouth to Cosham was officially inspected by Major-General Hutchinson, on behalf of the Board of Trade last week. The contractor was Mr. J. Sheppard, of London.

A new vicarage is being built in Waterloo-road, Wolverhampton, for Christ Church parish. Mr. S. Pountney Smith, of Shrewsbury, is the architect, and the tender of Mr. Richard Price, of that town, has been accepted for the work.

Mr. Hawkesley, C.E., has proposed a new scheme for the drainage of the Lower Thames Valley upon the instructions of the Main Sewerage board for that district. He proposes to convey the sewage-treatment in any manner directly into the estuary of the Thames near the mouth of the Darent.

PARLIAMENTARY NOTES.

THE METROPOLITAN BRIDGES.—Last Friday a Select Committee of the House of Lords passed the Bill, which has already received the sanction of the House of Commons, authorising the Metropolitan Board of Works to construct new bridges at Battersea and Putney, to widen and rebuild the existing bridge at Deptford Creek, to alter Vauxhall-bridge by converting the three central arches into one, and for relieving the Hammersmith-bridge Company from all obligation or liability as to the repair and lighting of the bridge and its approach roads. The new bridge at Putney will be a granite-faced structure, erected at a total cost of £106,000, upon the site of the aqueduct conveying the pipes of the Chelsea Waterworks across the river, the mains of which company are to be laid in the footways of the new bridge. With respect to the new bridge at Battersea, the Committee have authorised its construction with the curved approach. As now sanctioned by both Houses, the bridge will be an iron structure, erected somewhat to the east of the present bridge, at an estimated cost of £231,000. The width will be increased from 23ft. to 40ft., and the number of spans decreased from 17 to 5, the centre of which will be 173ft. wide. The new bridge will be 6ft. higher than the present one, which will allow 15ft. above Trinity high-water mark.

THE ARTISANS' DWELLINGS ACT.—Last Friday afternoon Sir R. A. Cross, the chairman, and several members of the Select Committee of the House of Commons, appointed to inquire into the working of this Act, paid a visit to East London for the purpose of viewing some of the sites taken for the erection of blocks of buildings under the Act and to inspect some of the houses already finished.

GUILDFORD, KINGSTON, AND LONDON RAILWAY.—A Select Committee of the House of Lords on Tuesday passed that portion of the Guildford, Kingston, and London Railway which it was agreed should be constructed by the South-Western Company, but have refused to sanction the branch line which was to have crossed Great Bookham common to join the South-Western, and London, Brighton, and South Coast Railways at Leatherhead. As the other branches to Little Bookham and Ashstead were abandoned in the House of Commons in favour of this Leatherhead Extension, the Bill, as now passed by the Lords, will only authorise the construction of the main line, without branches from Surbiton to Guildford. The other portion of the line from Surbiton to Fulham, which is to be constructed by an independent company, has passed unopposed.

STATUES, MEMORIALS, &c.

THE LATE LORD LAWRENCE.—Mr. Woolmer's bust of Lord Lawrence in Westminster Abbey was unveiled on Tuesday. The bust stands, on a pedestal representing the Indian lotus-leaf, against the north wall of the abbey on the west of the gate called the Canons' door, and nearly underneath the monument of Sir James Outham. The breast is draped in the robe of the Star of India. Over the heart is worn the star of the order. The face finely expresses the power which Lord Lawrence exercised over those who approached him. The forehead is very high and capacious; the distinctive features of the face are the deep-set eyes protected above by unusually low, straight brows. While the general cast of the face is such as to convey the idea of a commander who would irresistibly enforce his will and compel obedience, the expression of the mouth is singularly sweet and simple. The lines are large and strong, but the finely-pointed lower lip indicates extreme sensitiveness. The sides of the pedestal are decorated with incised and gilded lotus flowers, and in front is the inscription.

STAINED GLASS.

BARNSTABLE.—A large stained-glass window, the work of Mr. W. F. Dixon, London, has just been erected in the parish-church of Barnstable, to the memory of the late Frederick Richard Lee, Royal Academician, who was born at Barnstable, June 10th, 1798. The window was erected by his daughter, Mrs. Colonel Hibbert.

BRISTOL.—During the past month, Messrs. Camm Bros., of Smithwick, have fixed at Christ Church Congregational Church, Sneyd Park, Bristol, a handsome and costly stained-glass window, to the memory of Mrs. Derham, wife of Mr. James Derham, of Sneyd Park. The window is situated at the west end of the church. No fewer than 18 subjects, typical of Old and New Testament history, are treated. The series comprise the Garden of Eden, with Adam naming the animals, indicative of human dominion over creation; the Expulsion from Eden, the Flood, the Offering of Isaac, the trial of Abraham's Faith, Jacob Blessing the Children of Joseph, Moses bringing the Tables of

the Law, Aaron between Living and Dead, with Censer by which he stayed the Plague; the Crowning and Anointing of David, the Translation of Elijah, the Adoration of the Magi, the Flight into Egypt, our Lord with the Doctors in the Temple, our Lord Blessing Little Children, the Sermon on the Mount, the Raising of Lazarus, the Crowning of our Lord with Thorns. In the tracery of the windows are representations of the Two Covenants, Aaron with the altar of sacrifice and incense, David with crook, crown and sceptre, Jeremiah weeping over the Ruins of Jerusalem, St. John with his emblems, St. Peter with a key, fish-boat, net and inverted cross, St. James, with an appropriate passage from his Epistle, "Behold, we count them happy who endure." At the apex on one side is Moses, as representative of the Old Dispensation, and St. Paul as chief of the New Dispensation, and in the central piece of the tracery is a representation of our Lord in Majesty, surrounded by cherubim and seraphim. At the base of the window is an inscription.

WATER SUPPLY AND SANITARY MATTERS.

LINCOLN.—The main sewerage of this city having now been completed, from the plans of Mr. Mansergh, the town council discussed on Wednesday week the mode in which the house connections should be made, and who should bear the cost—the ratepayers at large or the individual owners whose property was connected. Objection was raised to the proposal by the sewerage committee to require Stanford's patent joints for the connections, which it was said would cost 1s. 10d. per yard, whereas cemented joints, which had stood well in this city during twenty years past, and were also used in London, only cost 10d. a yard. On the other hand, it was said that cemented joints would not be safe in wet soil, and that the builders of Lincoln would, as a rule, support the use of Stanford's joint. In the end, all propositions made on the subject under discussion were withdrawn, and the sewerage committee were granted full discretion and power to act. The matter has evoked a warm controversy in the city newspapers, and Friday's *Lincolnshire Chronicle* quotes at great length from the report of Mr. S. S. Hellyer's fourth lecture on Plumbing published in the BUILDING NEWS, in condemnation of the Mansergh's trap, and the report of lecture is referred to by several of the correspondents.

LIVERPOOL.—The Earl of Powis yesterday laid the foundation-stone of an immense embankment across a Welsh valley, which will form a new lake capable of holding nearly 2,000,000 gallons of water. It is intended to give a supply of water to Liverpool (by pipes extending a distance of sixty-seven miles over and through mountains and valleys) of 52,000,000 gallons a day. The river Vyrnwy is the chief upper tributary of the Severn, and the waters of this stream, together with those of two affluents, the Marchmont and the Afon Cowng, will be impounded at Llanwddyn, by a dam or embankment of masonry, built across the valley, which will be 140ft. high and 1,255ft. long. The embankment arresting the water of the three streams will form a lake five miles in length, with an area of 1,115 acres. This water will be conveyed to Liverpool for the use of the inhabitants there, a distance of nearly 70 miles, in a triple set of pipes, each of a diameter of four or five feet. Three tunnels have to be got through—the Kirnant tunnel, about 2½ miles in length, and the Morda and the Oswestry tunnel, each under a mile in length. Oswestry and other towns on the route will take water from these pipes. The waters of the district are remarkably pure, and the drainage area from which they are collected is 22,000 acres in extent. The works are expected to occupy eight or ten years in their completion.

The annual meeting of the Sanitary Institute of Great Britain was held yesterday (Thursday) afternoon at the Royal Institution, Albemarle-street, S.W., under the presidency of Earl Fortescue. An address was delivered by the Chairman of Council, Professor F. S. B. F. de Chaumont, F.R.S., on "Modern Sanitary Science," and the medals and certificates awarded at the Sanitary Appliances Exhibition at Exeter last year were presented. In the evening the anniversary dinner was to be held at the St. James's Hall Restaurant, under the presidency of Prof. de Chaumont.

The President of the Local Government Board has visited her Majesty's ships, *Atlas* and *Endymion*, now moored off Greenwich, which are about to be used by the Metropolitan Asylums Board as hospitals for small-pox and other infectious diseases. They have been converted to their new use from the plaques of Messrs. A. and C. Harston, architects, and give accommodation for 200 acute cases, or 600 convalescents.

Our Office Table.

The preservation of gas service-pipes was the subject of a good deal of discussion at a late meeting of the Associated Gas Engineers of New England. Special stress was laid upon the destructive influences of the salt in the soil of seaboard places, and the secretary said that at Charlestown the wrought-iron pipes were sometimes found to be so corroded that a touch would crumble them; but so long as they remain undisturbed in the ground they continue to hold gas. The same state of things was reported from other seaboard places, and it was also stated that gravelly soil and land filled with ashes were almost equally as bad. Indeed, one official stated that the pipes in his city were so badly acted upon in the gravelly soil that the loosening of the ground about them by the watermen, and even the shovelling of earth upon them, would make five out of six leak badly. Galvanised iron pipes are being put in in many places, and are much more durable; but they cost 50 per cent. more than common pipes, a weighty objection, which applies as well to lead pipes. Cast-iron pipes are not in favour among American gas-men, and the only practicable thing seems to be to find some process to make the wrought-iron pipes more durable, and at no great expense, or to use some other material than iron. Favourable results have been obtained by dipping the pipes in tar or asphalt, and by lining them with cement; but this latter method materially diminishes the capacity of the pipe.

The French difficulties in Tunis have brought the following little game to light, which has, it is said, been carried on for a long time at Carthage. Four or five cicrones who lounge about the place lead the visitor from one place of interest to another—from the pretended palace of Neptune, a heap of rubbish, to the pretended Senate House. At a proper moment the guide pokes his cane into a hole, and startles everyone by the discovery of a rich old mosaic, which he hastens to sell to the visitor. The mosaic is made in Marseilles, and the investment-yields a percentage unheard of even in Capel-court.

Ten years ago, the roofing-slate industry in the United States was not considered of sufficient importance to receive even a bare mention among the "special industries" of the census reports. Last year the capital invested in the manufacture of roofing slates amounted to more than \$8,000,000. Over 3,000 men were directly employed producing 600,000 "squares," or sufficient to cover 60,000,000 square feet. The quantity produced in the several States having slate quarries was:—Maine, 60,000 squares; Vermont, 130,000 squares; Pennsylvania, 320,000 squares; New York, 10,000 squares; Virginia and Maryland, 20,000 squares; other localities, 60,000 squares. The Pennsylvania quarries, which produced more than half the slate turned out during the year, have been worked about 15 years. The largest quarry was opened in 1865. It contains 60 acres, gives employment to 200 men, and produces 40,000 squares a year. The most durable slates are those from Southern Pennsylvania (Peach Bottom) and the Maine slates. The latter rival the best slates of Wales. The dark blue or blue-black slates are most durable. The fancy coloured slates—green, purple, red, variegated, &c.—do not hold their colour. Red slate is most expensive—during the past season from 7dols. to 9dols. per square. The Peach Bottom slates have ranged from 5.50 dols. to 6.50 dols.; Maine slate, 5.50 dols. to 7.75 dols.; common Pennsylvania, 1.50 dols. to 3.25 dols.; Vermont purple, 5 dols. to 5.50 dols.; green and variegated, 3.50 dols. to 4.50 dols.

The Sir Gilbert Scott Memorial Brass in Westminster Abbey was unveiled on Wednesday last by Archbishop Jennings, in the absence of the Dean of Westminster through illness. A large number of architects and personal friends of Sir Gilbert Scott were present. The archdeacon made a short and suitable speech, mentioning a few interesting facts in connection with his personal relationships with Sir Gilbert Scott. The brass is a very handsome monument, beautifully executed, and it is situated near the pulpit in the nave, immediately adjoining the grave of Sir Chas. Barry, R.A. A drawing was given in our pages on Sept. 12, 1879.

ARRANGEMENTS for the forthcoming industrial exhibition at the Hotwells, Bristol, are progressing rapidly. Messrs. Ford and Co. are proceeding with the building which is being erected under the superintendence of the architect, Mr. H. E. Edwards, and is now in a comparatively forward state; 613 persons have sent in their names as exhibitors. The committee have attracted exhibitors not only on a large scale in Bristol but from all parts, including Cheltenham, Worcester, and Swindon. The exhibition will be formally opened on Monday, the 25th inst., by the Mayor. The departments will be all well filled, and include models, working models, specimens of home handiwork in connection with all manufacturing trades and businesses, needlework and cookery, plants, flowers, fruits, and vegetables, fossils and natural history objects, &c. The industrial and art sections will receive additions until the 16th inst.

At the Industrial and Fine Art Exhibition recently held at Plymouth, the Gold Medal was awarded to Messrs. Goad and Co., marble merchants, who were also the recipients of the Silver Medal for workmanship. Their exhibit consisted principally of immense marble blocks, weighing several tons each, and forming part of the dome piers intended for the new church of the Oratory, South Kensington, of which Mr. Herbert A. K. Gribble is the architect.

SPEAKING about the Walker Art Gallery at the last Liverpool Council meeting, Mr. Rathbone asserted that, when any artistic brickwork had to be done in Liverpool, London bricklayers had to be procured to do it, and he deplored this as a sad state of things. Mr. J. C. Edwards, of Rumbon, writes to a Liverpool contemporary that there are but three instances in which London brickwork has been introduced into Liverpool for its artistic value. The principal one is probably that built for Messrs. Agnew, at the corner of Castle-street. Here it acquired the term "sensation" brickwork; for what reason Mr. Edwards says he cannot say, unless it is that "sensations" usually last but a few days, and that was the case with some of this brickwork. Passers by may remember that the building had been erected but a few months before the proprietors discovered that their ground-floor exterior was gradually passing away, and found it necessary to replace it with work of a more substantial and less "sensational" nature. Having been connected with brick and terra-cotta work, both in London and Liverpool, Mr. Edwards unhesitatingly asserts that Liverpool bricklayers are as capable of doing good artistic brickwork as any body of men in the country. It would be difficult to instance better workmanship than is exhibited at St. Francis Xavier's College, or at the Eye and Ear Hospital in Myrtle-street; and as a specimen of individual skill, the terra-cotta pulpit now at Messrs. Norbury's Art Rooms could not be surpassed. And these were constructed entirely by Liverpool journeymen.

We are asked to say that plumbers' exhibits for the International Medical and Sanitary Exhibition must be sent, addressed to "Mr. Mark H. Judge, Exhibition-road, South Kensington, S.W.," on or before Tuesday next. Invitation cards for the opening ceremony will be sent to all plumbers intending to exhibit if their names and addresses are received by Friday. Season tickets will be given to them as soon as their exhibits are sent in.

CHIPS.

On Saturday the new Mynydd-Mawr Railway, near Llanelly, was formally inspected on completion by the directors and shareholders, accompanied by the engineers, Messrs. Kinnipie and W. Rosser.

An inquiry was held at the town hall, Herne Bay, on Saturday, by Mr. Arnold Taylor, C.E., an inspector of the Local Government Board, with reference to an application from the urban authority for leave to borrow £1,000 for a breastwork and general improvements.

George Pilshan, foreman to Mr. S. Quelch, builder, of Egham, was committed for trial on Monday on a charge of having fired at and wounded with a revolver a fellow-workman named William Hazell, when at work at Salt Hill, Slough.

A new organ was opened at Kirk Arbury parish-church, near Castletown, Isle of Man, on Sunday week. It has been built by Mr. Hewett, of Leicester.

The foundation-stone of a new Wesleyan chapel was laid in Canterbury-road, New Brompton, next Chatham, on Friday. Messrs. Naylor and Son, of Rochester, are the contractors, and the cost of erection will be £1,800.

On Tuesday afternoon Mr. C. R. Jackson, chairman of the Building Committee, laid the foundation-stone of a new wing to the present hospital at Fulwood Workhouse, near Preston. The building will comprise an additional hospital ward and a ward for infectious cases, and is to be called the "Jackson wing." It will accommodate about 124 patients. The contract is let to Mr. R. Saal, builder, of Preston, for £10,323, and the work is to be completed in twelve months.

At a general assembly held at the Royal Academy on Wednesday evening, Mr. Edwin Long was elected a Royal Academician.

The death is announced of Mr. George Zobel, the mezzo-tint engraver, at the age of 70 years. Mr. Zobel, who had long resided at Brixton, frequently executed works for the Queen, the Prince of Wales, and other members of the Royal family, and was a regular exhibitor at the Royal Academy.

At the Lancashire quarter sessions held last week, plans for the erection of a magistrate's court-house at West Derby, at an estimated cost of £36,000, were approved.

At a meeting held at Chelmsford on Tuesday, plans by Mr. F. Chancellor, of London and Chelmsford, were approved for a cemetery lodge to be built in Rectory-lane, at a cost of £100, and he was also appointed architect for a proposed mission chapel at Rainsford-end. A meeting was held at Moulsham, a suburb of Chelmsford, on Thursday, when Mr. Chancellor's plans for the enlargement and improvement of St. John's Church were adopted; the scheme includes the provision of a tower and additional accommodation for 120 persons, and the estimated cost is £1,600.

A brass lectern has just been placed in Holy Trinity Church, Newington, S.E., in memory of the late Mrs. Armstrong. It was supplied by Messrs. Jones and Willis, of Birmingham and London.

The Cotswold Archaeological Society visited the Forest of Dean on Friday last.

A new engine and centrifugal pump erected at Tattershall for the drainage of the Timberland and Tilney Thorpe Fens were formally started last week. The engine is capable of working up to 150 horse-power, and the centrifugal pump lifted at the trial 120 tons of water per minute to a height of 11ft., discharging it from the fen drain into the river Witham. The work has been executed for the Timberland drainage trustees, by Messrs. Tuxford and Sons, of the Boston and Skebeck ironworks, under the supervision of their engineer, Mr. J. E. Williams, of Boston.

The Bromsgrove local board decided last week to call in Mr. Purchas, C.E., of Worcester, to report as to the best means of draining the extension area of their district.

Mr. S. H. Ferry, C.E., Local Government Board inspector, held an inquiry on Tuesday week at St. George's, Gloucestershire, into an application from the local board of St. George's for sanction to borrow £5,000 for providing a cemetery for the parish. The plans had been prepared, and were shown by Mr. W. Dawson, the surveyor to the local board.

Extensive additions are about to be made to the Bolton bank premises at Atherton, from the plans of Mr. George Woodhouse, architect, of Bolton.

A new Roman Catholic Church of St. John Curtius and St. Nicholas, at Broxburn, near Linlithgow, N.B., was consecrated on the 7th inst. It is Gothic in style, seats 600 persons, and was built at the cost of the Countess of Buchan.

A two-ton bell for Eddystone new lighthouse was cast at Messrs. Gillett and Bland's foundry, Croydon, on Tuesday afternoon.

Holloway's Pills—the sheet anchor of the confirmed dyspeptic. A few trials will prove their potency in removing indigestion, biliousness, nervousness, loss of appetite, want of sleep, and that utter weakness which waits on a cold and disordered stomach. They act as a laxative, sedative, and gentle purgative.

MEETINGS FOR THE ENSUING WEEK.

SATURDAY (TO-MORROW).—St. Paul's Ecclesiastical Society. Day visit to Rochester. Train from Victoria 10.10 a.m.
Opening of Sanitary and Medical Exhibition, South Kensington.

Doultling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to

CHARLES TRASK,
Norton-sub-Hamdon, Ilminster, Somerset.
—[Advrt.]

THE BUILDING NEWS.

LONDON, FRIDAY, JULY 22, 1881.

DOMESTIC BRICK ARCHITECTURE.

IT would be thought a downright piece of mannerism now, to plan a building upon the formula laid down by the followers of Vitruvian or Palladian precepts, the adoption of which would throw the principal apartments into symmetrical groups, with a prostyle hall in the centre, the whole design being arranged in reference to an axis and one of the Five Orders. Such a method of procedure would, at least, involve some trouble, measurement, and adjustment of parts. It would require the principal apartments to be arranged as wings, and the windows would have to be set out with reference to an order of columns, the proportions of which would control the heights of the whole composition. The plan at every step would be governed by the elevation, the demands of which are imperative. Comparing this mode with our modern haphazard system of arrangement and composition, nothing can be imagined more opposite. It was the outcome of pedantry, it is true; but it necessitated careful adjustment of parts. Those of the "Queen Anneists" who have been furnishing up their scraps of Classical detail, often lose sight of the consistency and proportion which were the ruling principles with the architects of antiquity and the Renaissance. But then we shall be told this incontinuity and disproportion is of the very essence of the style, without which it loses its charm and association. It is useless for the Classicist or purist to talk of modules or "minutes," entasis, or intercolumniation, the gradation and projection of orders—such learning is deemed only pedantic, perfectly soulless, and to be only of use to instruct people how not to become artistic. According to modern canons and taste, the very essence and feeling of art is expressed in the dictum that to become artists we must unlearn all rules, and affect an abhorrence for all methods. It is true enough that the real artist ought never to show his art, or parade it, and this truth has found expression in the aphorism—"True art is to conceal art." At least it is the delight of the artist in this last phase of architectural taste to depart as much as he can from those generally-received proportions which have usually guided the architect in both Classic and Gothic. As regards such fundamental things as the proportion of openings, doors, and windows, it is nothing unusual now to see doorways of extremely wide proportion, often quite square, and seldom higher than one and a half times the width. The panels of doors are made to increase this apparent width by being often in one without the usual vertical middle muntin. The question is, is there any gain by adopting such proportions, and if not why are they used? We certainly do not mean to assert that the modern joiner's idea of proportioning a door is perfect, such for instance, as the rule of thumb of 6ft. 8in. by 2ft. 8in. Modern house-doors of an ordinary kind are ridiculously narrow, and give an air of insignificance to a house; but we think there is no good reason for returning to a proportion which defies every principle. The ordinary canon for the human figure may reasonably be added as giving, with a fair margin, something like an approximate width of openings, and this rule agrees fairly well with the dimensions usually considered to be agreeable. The excesses of dress,

such as the farthingale, the pantaloons, and other extravagancies of the reigns of Elizabeth and Charles II., may probably have influenced architects in the proportions of doorways and staircases; but modern taste in this particular has undergone a great revolution, and the fashionable architect might be asked to give a reason for so glaringly violating one's sense of fitness. Windows are made all sizes, and the extremely narrow opening has become a favourite with artists of this school. But rule here also is set aside, for we see very wide openings as well as very narrow ones, and all of various heights and levels of sill line. Large mullioned arrangements on the first floor over very small casements in the ground-story are exceedingly common, in spite of their evident incongruity in houses of only two stories. We should have nothing to complain of if these openings were regulated by the requirements of the interior; but their authors do not even pretend they are, much less that they should appear proportioned with any regard for architectural propriety. The ingenious theories of Lebrun and others would be ridiculed, probably, even if they had ever been known by some of the school, and it would be worse than useless to tell these contemners of method that the most beautiful forms and proportions they sometimes copy with delight have been found to correspond with an obvious principle based on reason, that the load should not be apparently much greater or less than the support; in other words, that the voids and solids should be about equal. To take the best examples of the Orders, or the highly-pleasing arcades given by Palladio, Vignola, and other masters of the Italian, it has been found that there is an equality between the superficial area of the solid parts of the load and supports which may be easily tested by a geometrical method, and that, if we regard the solids and voids, the areas of each are in the more monumental examples found to be equal. It would be absurd to drive Lebrun's or any other theory so far as to say all openings and supports should be proportioned upon this system, yet the simple knowledge of a good ratio, say that which makes the solid part of an arcade about two-thirds of the void, or dictates the double square used by Vignola and other masters for the doorway or window-openings, might lead to an avoidance of what is positively ugly or painful to our sense of good proportion.

The employment of columnar orders is sometimes attempted. The very spirit of the style forbids the use of columns and ordinances according to rule, and the best specimens of "Queen Anne" or "Free Classic" are those buildings in which they have been very sparingly introduced. A very common decoration is the brick pilaster reduced to either a mere strip of vertical projection of about 15 diameters in height, or a squat-looking shaped form with dropsical entasis half the height usually seen. As merely brick relief we are not justified in charging these decorations with being violations, though they sometimes appear in positions which demand more regard to orthodox proportions, and there is certainly no excuse for making them so grotesque as to become ridiculous parodies. Such things as a squat-brick pilaster carrying a broken frieze of its own height and a bare member or cornice, and near it, another loaded with a projecting pediment of crushing size and weight or with immense carved trusses of considerable projection over a doorway, are too Hudibrastic for everyday art. They may provoke a smile; but what shall be said for such inanities as a little pediment, full-membered, with cornice a few inches long, stuck over the centre of a wide window having no apparent support except the glass! There is

a wide field for sensible brick architecture borrowing from 16th, 17th, and 18th-century models, and for everyday domestic life the style of either of these periods has something more real and honest than either Italian or Gothic of the Epochal types; yet if it is to take any permanent place in art it must cease to become the vehicle of the mere comical and buffoonish.

It is thought by many artists that even these qualities redeem a work from a dull and spiritless stereotypism. Rather than be mediocre let us be capricious, they argue; and as sensation is the order of the day, they make some little stir by their extravagances. Time works rapid change. Wonder at the audacity of the performance very soon ceases, and any admiration the work once extorted, on account of the daring and *verve* exhibited by its author, soon dies away before that stern and relentless arbiter—common-sense.

THE INTERNATIONAL MEDICAL AND SANITARY EXHIBITION.

THE Medical and Sanitary Exhibition, formally opened last Saturday by the Right Hon. Earl Spencer, occupies the greater portion of the annexes of the Royal Albert Hall at South Kensington. The Horticultural Society's gardens, with their wealth of foliage and flowers, add to the attractions of an exhibition, in itself rather dry and uninviting in its details, and the long arcades and quadrants skirting the gardens seem admirably adapted for exhibition purposes, in spite of some drawbacks of a practical character. The exhibition has been divided into no fewer than 17 sections. Sections I. to VI. are chiefly devoted to the exhibition of surgical instruments and appliances for hospital purposes; another section is given to drugs, dietetic articles, and mineral waters; electrical apparatus, optical, medical, physiological, and other appliances form four other of the sections; section XIII. represents hospital architecture and construction; section XIV. is given up to ventilating, lighting, and warming; section XVI. illustrates water supply and filtration, and the last section is devoted to a miscellaneous collection of objects, school-furniture, clothing, and books. Each of these sections is presided over by competent judges and specialists, who are now preparing their awards, and the list includes a few of our foremost authorities in medical and sanitary science. In the section (XIII.) devoted to domestic and hospital architecture, planning, and construction, which we notice on another page, we find the judges' names include Sir Joseph Fayrer, K.C.S.I., M.D., G. Aitchison, A.R.A., F. Mouat, M.D., Edward C. Robins, F.S.A., P. Gordon Smith, Professor T. Roger Smith, Henry Saxon Snell, and Alfred Waterhouse, A.R.A.

This and the following sections comprise nearly every department of sanitary science, and it is to these we shall chiefly devote our attention. The sanitary sections occupy the largest area. Entering the eastern arcade from the main entrance in the Exhibition-road, we find the space has been allotted chiefly to exhibitors of sanitary goods under sections XIII., XIV., XV., and XVI. Sanitary apparatus, ventilating and warming appliances, drain-pipes, traps, innocuous oil-paints, improvements in heating stoves, and appliances for opening pivot and other sashes, are largely shown. These several articles have not, unfortunately, been placed in any order; our notes, on this account, will necessarily appear rather unmethodical. A large full-size model of a window, with sashes, near the entrance end, exhibited by John Bryden and Sons, shows a clever contrivance for opening and closing, by means of cords and pulleys, also a

pivot-sash for hospitals, intended to be under control of attendant only. An arrangement of levers at the side of the sash-frame is the principle adopted. We also notice a variety of bell-hanging appliances, electric, pneumatic, and mechanical, of excellent make. Sanitary paints are numerous, and shown by several firms. Decoration is not largely represented in the exhibition, but for walls, Fredk. Walton and Co.'s specimens of dados and wall-surfaces leave little to be desired, either on account of their artistic or sanitary advantages. The material is that known as the "Lincrusta-Walton." The specimen with the fillings and dados of a bronze-colour, richly embossed, and another shown in the Adams style are admirable examples of effective and cheap decoration. These are made of oxidised linseed-oil and wood fibre, and the relief is as sharp and clear as wood-carving.

Passing the Shone Drainage Co.'s exhibits, with models of the automatic sewage-ejector and flushing apparatus; we meet with a simple self-acting flush-tank in operation, made by Maguire and Son, Dublin. The firm also exhibits a plan of house-drainage and ventilation, in which the drains are laid upon an improved plan in connection with an air-shaft and inlet. The "patent safety joint-drain" is a great advance on the ordinary drain-pipe with its irregularity and imperfect jointing. In this plan, each joint is laid in a sort of cradle filled up with cement, and every other pipe has an opening for inspection. The line of pipe is kept in a true concentric position; every joint rests on a solid bearing, and is not dependent on loose ground, or the cement being run in on the lower half of socket, a solid water-tight joint is made in a part where pipes are apt to leak. The Thames Bank Iron Company exhibit a variety of warming and other apparatus. Our attention was particularly called to an improved gill stove, the peculiar feature of which is that it is formed of segments, fitting together without bolts and free to expand. The heating-surface is considerable, and the gills break with each other instead of being in a line. The stove can be set in brickwork, having cold air and warm air ducts. A large, full-size model of an apparatus for opening conservatory or laundry windows is shown. The lights comprise a top light and a side light, and both can be easily opened by rods acting on levers and arms. It can be fitted up at about 4s. a window. A cast-iron skirting, with 2in. water-pipes, and some coil columns and cases, are exhibited. The india-rubber ring for hot-water pipes is a useful means of preventing the effects of expansion and contraction.

Messrs. Wilcock and Co., Burmantofts, Leeds, have a large and very noticeable stall in the arcade. The specimens of this firm's very beautiful faience, in a variety of decorative forms, cannot fail to be appreciated for their artistic designs and pleasing shades of green and brown. The panels, friezes, string-courses, and moulded work are of very excellent manufacture; and one of the principal exhibits is a Moresque arch composed of voussoirs, arranged in a star-like shape, and relieved with a rich arabesque on the surface. These are all hand-moulded. The designs shown give a good idea of the capabilities of the material for architectural purposes. We now draw the visitor's attention to a few sanitary articles made by this firm, which show how stoneware may be applied to such things as troughs for closets, mangers, sewers, siphon-traps. Wilcock's trough closets (Holroyd's patent), possess the qualities of durability, non-absorbency, and cleanliness. They are salt-glazed, and are admirably suited for large establishments, schools, and workshops. The troughs can be made in one by socketed joints if several closets are re-

quired, the division-walls being of common or glazed bricks. A perforated flushing-pipe flushes the whole length of trough, and is placed under the rim of trough, and a valve-chest is provided for every six or twelve seats at the end of the row. The seats are of pitch-pine. The sanitary manger and cattle-trough are two valuable manufactures, and the specimen tube of 2ft. diameter, the patent gullies, and the large double siphon intercepting arrangement seen among the sanitary exhibits of the firm show the capabilities of the clay for purposes of sewerage and drainage. The next exhibitor is Mr. J. E. Ellison, of Leeds, who not only has an interesting display of ventilating arrangements on the conical-aperture principle, both for the exterior and interior of buildings, in the shape of perforated bricks, ventilating skirtings, &c., but also exhibits several forms of his air-diffuser for the admission of air to rooms. One of these is a square disc of polished wood, with the apertures formed by diagonal pieces in the form of a cross. This very simple contrivance, which any carpenter can make, is made to slide within a case or frame let into the wall in communication with the air inlet. The triangular openings formed between the case and the cross pieces become dispersers of the air. In another branch of sanitary work the Antiseptic Apparatus Co. shows a closet supplied with their patent apparatus for neutralising and destroying unpleasant gases, the principle of which we lately described in these pages. Nothing can be simpler in action, and the apparatus can be easily fitted to any closet at a trifling cost.

Messrs. Banner Bros., in addition to their well-known system, have several new inventions to record. We may draw particular attention to a system of ventilating apartments by clockwork, in which the motive-power is a small fan, which works in a case connected with the outlet, thus producing suction and expelling the vitiated air. Banner's railway-carriage ventilator is certainly a very ingenious application of the principle of the induced air-current ventilator, and its merit is that it can be applied to old carriages at a small cost, while it is extremely simple and sure in action. Mr. Banner introduces S-shaped openings over the carriage-doors, the sides of which apertures are made to project and form an oblique surface, so that, when the train is running, the inclined sides create a suctional effect at the opening by the air which strikes against them. Round the inside of carriage are rectangular tubes, with slits, for the passage of the vitiated air, and this tube, being connected with the opening already mentioned, becomes the means of drawing off the hot or respired air from the ceiling of carriage. The plan has the merit of efficiency and economy. Another invention, shown by a small model, represents a means for purifying the atmosphere of our underground tunnels. A vacuum is created by a travelling disc, by which fresh air is introduced, and the foul driven out.

Mr. W. P. Buchan, of Glasgow, has a stall in which several important modifications in drainage and ventilation are illustrated. Those who wish to become personally acquainted with the plans advocated by Mr. Buchan in the BUILDING NEWS will find an inspection of this stall an aid. The "Carmichael Wash-down Accessible Closet" is in one piece of earthenware, is an excellent and cleanly substitute for the ordinary closet apparatus, and the metal jet fan is very effective. The siphon form is extremely simple and effective; the basin outlet forms the trap, and is inserted into the lead soil-pipe. We notice also a few specimens of Mr. Buchan's "induced current ventilators," which are made of several sizes, from 6in. to 60in. diameter in the body, and of external forms to suit

soil-pipes or roofs. The systems of house-drainage and ventilation are illustrated by large diagrams, in connection with which we may notice the improved form of drain-trap, in which the water falls into the trap suddenly over a sharp angular edge, instead of a rounded edge, the effect of which is to remove all matter from the trap. The lid for cleansing or jointing, and the ventilation insured, make it one of the best in the market for simplicity and cleanliness of action. The anti-bell trap is a decided improvement on the old iron bell trap, which is constantly accumulating filth.

Messrs. Robt. Boyle and Son have a large and conspicuous stall on which are displayed a variety of forms of their well-known "air-pump ventilators." It is needless to say that Messrs. Boyle have made it their business to study every purpose for which a ventilator can be fitted. We notice several large handsomely-cased ventilators suitable for the roofs of public halls or churches, and in the leading styles of architectural design, though for ourselves we prefer the plainer and more honest forms in which the plates can be arranged, and several of these are exhibited. We notice a capital form of ventilator suitable for buildings where a down-draught is experienced; the plates are placed horizontally, and the outer casing is bevelled both top and bottom, so that a current of air impinging vertically or at an inclined angle at the top produces the desired vacuum. One model shows a case in the form of a small octagonal temple with columns and cupola, the plates being introduced in the arches of the octagon. The decoration in marbles and gold is very showy.

We must call attention to an improved form of socketed-pipe (Brookes' patent), shown by Edward Brookes and Sons, the sides having ribs cast upon them to give increased strength and better bearing; the same firm's large stoneware invert, the excellent fittings displayed by Haywood, Tyler and Co., and the tip-up lavatories and patent shower and spray shampooing apparatus, with combined hot and cold supply valves, exhibited by G. Jennings. The latter are manufactured with every requisite in a highly finished manner. A concealed urinal and a combined urinal and lavatory, and the automatic intermittent flushing apparatus and Dubois' ball-traps are all worthy of the inspection of architects and others who are looking out for improvements, elegance, and economy. J. Warner and Sons show a portable w.c. fitted with a pail below the seat which can be removed by hand, and having a tank with handle for flushing, and a self-acting valve-pan to the basin. Owen's patent trapped urinal combines lavatory, basin, and slop sink. It is siphon-trapped and ventilated. Messrs. James Stiff and Sons, Lambeth, are large exhibitors of sanitary stoneware, salt-glazed ornamental stoneware, and terra-cotta. Referring now more particularly to the sanitary exhibits, we saw a new portable drain disinfectant to be used for disinfecting drains, and another for hospital use. These are made in two different shapes of stoneware, cylindrical and conical, and chlorine-gas is generated inside and escapes by a tube from the upper end to the lower, thence discharging into the current of the drain. The disinfectant can be placed in any manhole or shaft. The end coming into contact with the sewage matter in the drain, the latter is disinfected. The firm also shows Weatherley's disconnector waste-trap, Weaver's sewer-air trap, and several good types of intercepting arrangements, yard gullies, &c. Weatherley's disconnecting and ventilating trap is a double siphon, and appears to combine the advantages claimed by several others. The terra-cotta Grecian doorhead and some architectural majolica claim the attention of architects. Messrs. Doulton and

Co., Lambeth, are well represented by a large stall crowded with Lambeth faience, the merits of which require no reiteration on our part. The sanitary exhibits are numerous, and many of them are well-known to our readers. Lavatories made in earthenware, Doulton ware, and wood, are handsome pieces of sanitary furniture. We note also a few capital slop-sinks, urinals of earthenware, closets, flush-out and trapless, valve-closets of superior make, stoneware drain-pipes, and Doulton's patent joint for pipes, the peculiarity of which is that the ends of the pipes are accurately ground at the junction, instead of having the usual socket. A circular fillet is cast on each pipe near the end, which allows of a cement joint of 3in. wide all round, the lower half of joint resting on saddle-pieces, so that settlement and breakage are avoided. The Stanford joint made by this firm, and Kenin's air-chamber floor and trap for intercepting sewer-gas and other specialties are exhibited. Sanitary forms of ironwork have received ample attention from the well-known Glasgow firm, Walter Macfarlane & Co. The exhibits occupy one of the largest allotments of room in the arcade, and the objects are sufficiently striking from their size to enlist attention. They come within five sections. We notice two or three urinals on the square and circular plans, remarkable alike for their clean sharp casting, and the attempt to make these unsightly excrescences ornamental.

Messrs. Steven Bros. and Co., of Upper Thames-street, are large exhibitors of high-class ironmongery, baths, heating apparatus, ranges, stoves, &c. We observe the patent bath and fittings exhibit practical and sensible provision for the convenience of those who use them. The hot, cold, and waste are in a small compass and do not project unnecessarily, they are easily turned by the user without getting out of the bath. The bath is made of cast-iron. We notice also an earth-closet (Moser's), a handsome electro-plated kitchener, with tiled back and sides, fitted with cone ventilators at top, to carry off the fumes from cooking, and dampers drawing from the front. The combined open and close fire and the convertible register-stove are both clever modifications. A novel kind of heating and ventilating apparatus is shown by Mr. G. E. Pritchett, F.S.A. It is one bay of a hospital ward, lined with Ree's metal tiles, and fitted with corrugated double plates, between which the hot water circulates. The heated plates are made to form a kind of dado. Fresh air is supplied at the base and is admitted warm at the required height through adjusting louvres. Heated plates along the cornice cause the ventilated air to ascend, and is carried away at the roof-level. The plates have a larger heating-surface than pipes, and occupy hardly any space, and being smooth do not harbour dust, so that the system is well adapted for fever-wards.

Messrs. J. Tylor and Sons have an assortment of valves and traps for water supply, and their patent ground-joints, doing without solder, are capable of standing high pressures. We notice also some water-meters, an automatic arrangement for registering, pumps of improved manufacture, and various other hydraulic apparatus. Architects will find the stall of Messrs. William Tonks and Sons, of Birmingham, well repay a visit. The architrave ventilators with Currall's patent, adapted by Mr. Mark H. Judge, are inexpensive means for promoting a circulation of air above doors. Other patent ventilators for fixing in chimneys, and on doors and windows, may be seen. We notice also some excellent window-fasteners, Hopkinson's door-chains and bolts for allowing doors to be partially open—worth the attention of the profession; steel sash-lines of ribbon shape (Hookham's); case-

ment stays, keyed door-furniture, &c., showing many important improvements.

In the eastern quadrant the exhibits are even more numerous than elsewhere. Messrs. W. Woollams and Co. show an assortment of wall-papers of an innocuous kind, in bright and neutral colours. They are manufactured free from arsenical pigments, and at very moderate prices. Messrs. Rosser and Russell compete well with other exhibitors in their reversible grate for smoke-consumption. It has a revolving fire-basket, so that the fire can be lighted and reversed, and the products of combustion are thus consumed. The grate has a neat and artistic appearance, and its construction commends it to the consumer. The range and boiler safeguard, and the warming and ventilating apparatus, are useful and efficient articles, and their model of glazing-bars for green-houses, &c., is certainly simple and watertight. We recently described the bars in detail. Messrs. Smith and Stevens are exhibitors of Russell's "Binate door furniture," which is made in one solid piece of wood. They also show a variety of fittings, and furniture, hot-water apparatus, coil-cases, baths, and fittings, and architects will find little in the furniture of houses, churches, or schools unrepresented. Their weathertight sill-bars and casement fastenings are specialties which call for attention. The "hook-bar" is a simple and effectual check for casements.

Passing a large display of art metal-work, we may notice Messrs. Fredk. Edwards and Sons' specimens of the new smoke-consuming slow-combustion grate, the advantages of which we recently enumerated. This grate, with its blind fitted so as to move downwards in front of the burning fuel, is a modification of Dr. Arnott's, but without the sunken ashpit. It has a neat and artistic appearance. The blind is well-managed by counterbalanced weights, which are concealed by projecting cases on each side. These are made ornamental. Sufficient coal is put on the grate to last for a day, the fire is made at the top, and the coal burns downwards. The warm air-chamber is supplied by an inlet, and before the fire is a neat fender guard, and a cinder basket and dust-trough are fitted below the grate. Economy is secured by a valve, actuated by a chain at the top of grate. Another form of grate is well adapted for infirmaries and railway-stations, and the invention is a decided step towards the abolition of smoke. Messrs. Verity Brothers' large and handsomely fitted up stall cannot fail to attract the visitor. The rapidly revolving fan or air propeller, acted on by a small jet of water, and the vertical tubes of various sizes and descriptions, which discharge the air into the room on this plan of ventilation, may be inspected in actual operation. The opening at the top of discharge outlet can be regulated at pleasure, by which the in-current can be diverted. The tubes are made also to open, to admit of a moistened sponge to cleanse the air, or of ice in hot weather to cool the air, or a box of disinfectants may be introduced. Messrs. J. Weeks and Co.'s hydro-caloric coil, lately described by us, and various other appliances for warming and ventilation, will enlist the attention of all those who are endeavouring to economise and simplify existing systems. Square and circular coils are to be seen, and we may especially draw attention to a vitiated-air extractor, in which a coil is placed below the cornice, thereby creating an up-current for the extraction of foul air. The inventors show the application of their coil to horticultural buildings. Messrs. Musgrave and Co. are the exhibitors of several slow-combustion stoves of superior manufacture, made of iron with firebrick linings. A number of handsomely-enamelled tile stoves on the same principle are shown, a hot-air

stove for placing in a brick chamber, and other exhibits, including stable-fittings.

Messrs. Benham and Sons are another large firm of exhibitors. Among other exhibitors of articles we must describe more in detail next week we may name the "Eureka" Concrete Co.'s stall, showing a large model of a stable, indicating method of laying a "Eureka" concrete sewer and invert concrete pipes, well worthy of the attention of all engineers, architects, and sanitary bodies. For paving fireproof floors, railway platforms, as well as for all architectural purposes for which stove or brick are now used, the Eureka concrete is admirably adapted. The specimens of concrete by Charles Drake and Co. show how ornamental a material concrete can be made by the admixture of marble fragments. The exhibits comprise a marble concrete bath, cast in one piece, polished; a Drake's mosaic marble jointless concrete pavement, 8ft. by 6ft., with Grecian scroll and border-lines in red, black, and white marble concrete; a specimen slab of fireproof concrete floor, with structural ironwork encased in fireproof concrete, illustrative of Drake's specialty in monolithic fireproof staircases, upper floors, and roofs; mosaic marble concrete hearth, cast in one piece to fit fireplace and fender, in various coloured marbles; mosaic marble curb fender of white marble, highly polished, and stated to cost much less than solid marble; specimen pieces of monolithic concrete walls, built with Drake's patent dovetailed self-fixing concrete building slabs; samples of floor and wall tiles and slabs in mosaic marble and granite concrete; and photographs of important buildings erected in concrete by Messrs. C. Drake and Co. The marble tiles, floor, and polished walls are worth attention. Mr. Joseph Constantine exhibits in the quadrant also his patent convoluted stove to which we lately referred at some length. Messrs. Gillow and Co. have a few admirable lavatories designed for limited space, fitted up in walnut with earthenware basins; Messrs. Potter and Sons a revolving firegrate, invented by Mr. H. Saxon Snell, the object of which is to cause a more perfect combustion of the fuel by turning the lighted part of fuel below, also the better known "Thermhydryc" ventilating, hot water, open firegrate used in many infirmaries by the same inventor; Mr. Alfred Walker shows some capital specimens of his granite and iron slag concrete for paving purposes, railway platforms, &c.; Bellman and Ivey several beautiful specimens of their scagliola for columns and architectural decoration; Crossley Brothers the "Otto" silent gas-engine, and many other exhibitors are represented whom space prevents us even from mentioning this week.

HOSPITAL AND SANITARY CONSTRUCTION AT THE SANITARY EXHIBITION.

TO the architect and sanitary engineer the western gallery at the Medical and Sanitary Exhibition presents much that is instructive and interesting. There is a collection of several valuable drawings by leading architects, illustrating the planning and construction of recent hospitals. Among those who contribute to this section we may mention the names of T. Worthington, F.R.I.B.A., Professor Roger Smith, H. Saxon Snell, F.R.I.B.A., Mark H. Judge, E. C. Robins, F.S.A., Yeoville Thomason, F.R.I.B.A., Ernest Turner, F.R.I.B.A., H. G. Brace, A.R.I.B.A., Coe and Robinson, W. Chisholm, H. H. Bridgman, A.R.I.B.A., W. Eassie, C.E., C. O. Ellison, Captain Douglas Galton, C.B. A large area of the wall of this gallery is devoted to a series of plans, drawings, and photographs, illustrating Mr. H. Saxon

Snell's designs, published in his "Charitable and Parochial Establishments," recently noticed by us. Plans of St. George's Union Infirmary, St. Marylebone Infirmary, dispensary, relief station, and casual wards, the Holborn Union Infirmary, and various other institutions of the same kind are here displayed, and may give the architect and general visitor practical information of the most recent and approved buildings of this class. A set of drawings, illustrating the plans of the Freehold Cottage Dwellings Co., designed by T. Marcus Haughton, architect, may be noticed, not for any artistic merit, but as showing the arrangement of cottages for workmen, having six or seven rooms. Several classes are shown, costing in brick from £150 to £285. In the architect's concrete the cost is put down at from £135 to £255. Details of the drainage and ventilation are shown. Those interested in the planning of town hospital wards will regard with satisfaction the plans exhibited showing the reconstruction of the University College Hospital, as designed by Dr. G. V. Poore and Mr. A. Waterhouse, A.R.A. The general plan we may describe as partaking in shape of the letter **m**, the long connecting building to the three cross-blocks forming private wards as well as a corridor. The cross-blocks contain the wards, and are on the pavilion plan. Each pavilion is complete in itself, and contains three wards. One ward, 84ft. by 25ft., provides for seventeen patients, allowing 124ft. super. to each. The beds are placed opposite, along the side-walls, with windows between, and a scullery, bath-room, and w.c. are placed at the outer end, so arranged as to get a small balcony between the projection of the closets. The middle pavilion is of like length, provides for sixteen beds, and gives 117ft. super. to each. The arrangement in other respects is the same. It is placed 76ft. from the other blocks. The right-hand pavilion is longer, and projects beyond the corridor: it provides for twenty-five patients, and gives 123ft. superficial of floor to each. The heating is by stoves and open grates in the centre of wards. Equally distant from the wards are arranged staircases projecting from corridor into the areas, and these have lifts in the well-holes. The servants' bedrooms, kitchen, operating-theatre, clinical-theatre, &c., are on the fourth floor.

The Artisans', Labourers', and General Dwellings Co. are represented by several drawings, showing houses of the first, second, third, and fourth classes, from designs by Mr. Rowland Plumbe, F.R.I.B.A., the general plans of which are pretty well known to our readers. Mr. Mark H. Judge exhibits plans also of three-roomed dwellings for artisans, the area occupied by each being the same as that of an ordinary house. The plans show two dwellings in each, with separate entrances, yard, and offices. The elevation, relieved with red brick string-courses and arches, present neat exteriors, in which economy has been studied. A detail of the fireplace trimmer-arch shows that construction has been cared for. Mr. E. C. Robins, F.S.A., contributes several plans and views of infirmaries and hospital buildings. The premiated design for Hampstead Infirmary shows the pavilion arrangement of wards. The second prize design for the London Orphan Asylum, by the same architect, adopts a plan in which the blocks are all separated on the pavilion system, and are arranged round three sides of a quadrangle or rather octagon. The boys are placed on one side, and the girls on the other. Each block contains a kitchen, day-room, lavatory, &c., on the ground-floor, above which is the dormitory, with three rows of beds. About 50 beds are provided in each, and the size is 65ft. by 31ft. In the quadrangle oppo-

site the blocks are arranged the schools, and in the centre are buildings for the swimming-baths, playgrounds, and other purposes. The design is of rather too florid a Gothic type to please us. The plan for the North Staffordshire Infirmary is a plain but effective arrangement: the wards form pavilions, and have V-shaped bay windows, enabling patients in bed to look out. We notice, also, a five-pavilion arrangement for St. Pancras Infirmary, and the author's design for the City of London schools. Messrs. Coe and Robinson show their plans for the West Herts Infirmary, also the South Devon and East Cornwall Hospital, the arrangement being on the pavilion system.

One remarkable plan and design of a hospital adapted to the site of University College Hospital, on the circular-ward system of Professor Marshall, is exhibited by Francis E. Jones, architect, of Cockspur-street, which forms one of our illustrations to-day. The wards are in four circular blocks, arranged symmetrically in connection with the central administrative block, as shown by the plans we reproduce. The system of Professor Marshall is generally known, and as the author points out, the advantage of the plan is its suitability for a confined site, such as that of the University College Hospital. Another important point claimed in its favour is that only one point in the circumference of a circular ward is as near the houses on the opposite side of the street, as the whole long side of ward on the oblong plan. The wards are also practically unobstructed as regards light and air, by the administrative building. To reduce cost in building, which "circular work" would entail, the author makes the walls hollow, the external portion being made polygonal, and the inner half-brick ring circular, which latter would be plastered. The form being circular, the wards contain more superficial feet of floor-space for a given length of wall, and consequently the cubic air-space is greater also. Mr. H. H. Bridgman, A.R.I.B.A., sends a plan section and a perspective view of the proposed hydropathic establishment at Bournemouth. The design is in a florid Elizabethan style of red brick, and shows a large square central hall with the baths on both sides, and with the principal apartments on the main fronts. The same author exhibits his design for the Camden Turkish baths.

The plans of the new Lying-in Hospital, Madras, by Mr. W. Chisholm, are interesting, as showing arrangements in tropical countries. The wards are on the pavilion system, the labour-wards are in the centre block, and covered corridors connect it with the other pavilions. Each floor is a complete unit. Contagious diseases are provided for in distinct cottages in the rear. Mr. Lawrence Booth, F.R.I.B.A., shows the plan and elevation of hospital being erected for the sick and infirm of the Salford Union at Hope, near Eccles. The design is Elizabethan in style, with a touch of Queen Anne, and the plan shows a number of pavilions, single and double, connected by a long corridor, 850ft. long, with the administration-block in the centre. The wards are for 32 beds each, and each has a day-room at the corridor end, with nurses' room and scullery. The cost is estimated at £63 per bed for 880 beds—a moderate price compared with some buildings. A superficial area of 80ft. is given to each patient, or 1,000 cubic feet of air. We also notice plans of dwellings for workmen at Salford, by the same architect. Mr. E. O. Ellison's plans of hospital for eye-diseases at Shrewsbury, designed on economical principles, and for a separation of out- and in-patients, have good points; the ink perspectives, in a Gothicised style, show a pleasing breaking-up of parts for buildings of this character. We may also

note in passing the colossal plans for the Herbert Hospital, Woolwich, designed by Capt. Douglas Galton, C.B., one of the first important buildings on the pavilion system in England; the North London Convalescent Hospital, by Professor Roger Smith; three portfolios of drawings illustrating Prestwich Union, near Manchester; the Albert Edward Infirmary, Wigan; the Liverpool Convalescent Institution; and the Chorlton Union, near Manchester, from designs by Mr. T. Worthington, F.R.I.B.A.

Details of sanitary house-construction are to be seen in several drawings. We particularly refer to Mr. Henry G. Brace's sections and details of a proposed house at Addlestone, Surrey, showing details of ventilation. In this arrangement the hall is supplied by fresh air through glazed pipes; the air admitted is heated by a coil in the hall, and then enters over the doorheads of the rooms. The vitiated air is extracted through Dr. Ball's or Boyle's ventilators into smoke-flues. Mr. Ernest Turner, F.R.I.B.A., also shows plans for house-drainage. We notice the plan of drains at the Home Hospital, Fitzroy-square, and the plan adopted at some houses at Kensington. In all these cases the author has provided open-trapped gullies at the feet of all pipes and disconnecting chambers at the junctions in the areas. Through the latter the drains are made open channels. The same architect's steam-laundry, Battersea-park, is interesting. Messrs. R. B. Grantham's and Bailey Denton's design for abattoirs exhibits an improved plan of constructing these buildings, in which iron is largely employed in the roofing. The waterproof facing bricks by Mr. Lanchester, intended to be used to face walls of porous quality; the diagrams illustrating the ventilation of theatres and hospitals, by Dr. A. Tripiet; Mr. Yeoville Thomason's plans of sanitary arrangements; F. Siemens' model of crematory apparatus; Dr. Fred. J. Monat's elaborate plans of hospital at Montpellier, now erecting for 600 beds, besides other diagrams, will be examined with the attention they deserve. Sanitary construction and hospital architecture are here brought together in a more complete manner than we have hitherto seen, and we trust the present exhibition will be the forerunner of others of a more comprehensive kind.

THE GLASGOW MUNICIPAL BUILDINGS.

AFTER much disappointment, delay, and lengthened discussion, the Lord Provost, Magistrates, and Council of Glasgow have issued the conditions for a new competition, the text of which will be found in our advertisement pages. Most of our readers know the barren result of the first competition last year, the very limited margin of expenditure which fettered the selection of Mr. Charles Barry, the referee; and the general disappointment felt when it became known that some of the ablest designs were left out in the cold, not from any defect or demerit in their plans, but because they exceeded the cost imposed of £150,000. This misadventure was chiefly owing to the requirements of the Council exceeding the sum they intended to spend, and the framers of the new competition have wisely increased the limit of cost to the sum of £250,000. It would be of little use now to discuss the various suggestions which have been made by competitors with regard to a new competition, or to express the disappointment felt by many engaged in the last contest who achieved a high place, and who not unnaturally have asked that their labours and claims should have been acknowledged in a new trial of strength. It certainly appears a hardship that the best of the designs have gone unrewarded, and

that their authors have, if they enter the field again, to begin *de novo*, though on the whole the authorities have done wisely, we think, in deciding upon an open competition.

The proposed division into two competitions—one of sketch designs open to all, and another a final one, limited to the authors whose sketches shall have been selected by the assessors, will, we believe, meet with approval from all architects. It has been determined by the Council to appoint the assessors at once, and, we understand, Mr. Charles Barry and Mr. Carrick have been appointed to advise. We think a third assessor would be a source of strength. The functions of the assessors will be to select from the preliminary designs those authors who shall be invited to compete in the final competition, and to advise the authorities in the final selection of the four best designs, having regard to the cost and the estimates submitted. It is said that separate conditions will be issued for the final competition, though they will be in strict accordance with the above, but with additions suggested by the results of the first. We hope the second conditions will not needlessly alter or add, or the effect will be that the excluded competitors will have a fair right to complain of what they may justly call a new competition of a very limited number. It is to be hoped the Town Council will be guided by the assessors completely in this respect, and make up their minds to adhere closely to the conditions they have laid down. We may just glance at a few of the principal of the requirements, and, at the outset, we may congratulate the Council on clauses 11 and 12 of the new conditions. The diagram plans prepared by the city architect, to be supplied to each competitor, are not intended to control the designs in any way. They may be altered, as to internal arrangements and accesses, as each competitor thinks fit, and are to be considered merely as indicating the general departments. In the preliminary sketch-plans these departments are to be distinguished by colours similar to those used in the diagram-plans, and this requirement will aid much the assessors and those who may have to compare or criticise. We take exception to clause 7, which says:—"In order to obviate the possibility of the sketch-designs lodged in the preliminary competition being made use of by competitors who may be invited to enter into the final competition, such sketch-designs will not be allowed to be seen by anyone except the assessors to be appointed by the magistrates and council, by whom they will be returned direct to their respective authors." We scarcely see the advantages to be gained by excluding public and professional criticism, especially with regard to the first competition, which this clause is intended to do. Of what use can those who enter into the final competition make of sketch-designs which have been excluded for some inherent defect or shortcoming known to the assessors? If the clause means that a final competitor might unfairly avail himself of any arrangement of merit he has seen by a preliminary competitor, all we need observe is that that preliminary competitor ought to be found in the final selection of authors, and not be excluded, and the clause 25 becomes superfluous. The conditions would have been stronger and better without this clause. As to scale, the adoption of 20ft. to the inch for the general sketch-plans, elevations, and sections is sufficient probably; but why have these drawn to 20ft. to the inch, and the final drawings to a scale of 8ft. to the inch? Why adopt a decimal division in one case and not in the second? If 10ft. to the inch had been named as the scale for the final drawings, we could have understood the preliminary scale, and the first sketch-designs would have then been

just half the scale of the others. Again, if 8ft. to the inch is to be the scale in the second competition, why not make the preliminary scale just half that, or 16ft. to the inch? A 20ft. to the inch scale is certainly small. We are glad to find that a perspective view, taken on a picture line determined on the block plan, is included in the sketches, and that the size of the perspective has been limited, so that the building itself shall not occupy a greater width than 10in. We are also glad that pen-and-ink sketches, without colour, have been decided on, and that the question which gave rise to a controversy in the BUILDING NEWS respecting the admissibility of flat washes or line shading to the window-openings in the last competition, has been set at rest by allowing competitors to use a flat wash of India ink in the door and window openings, and in the roofs. Only outline elevations with such washes will be admitted. It is a pity the conditions have not made it necessary for competitors to show any details. A detail of any part of a building is a better test of competency than an elevation drawn to small scale.

The other technical requirements are generally clear: the ground-floor level is to be about 2ft. above the ground at the centre of the George-square façade, and about 1ft. above the street-level at the centre of the John-street façade. The site, as our readers know, is on the east side of George-square. Stress is laid on proper provisions for warming and ventilating the building, and details of all sanitary requirements are to be supplied by the competitors in the final test. With reference to the question of style, no restrictions are imposed; but preference will be given to Classic, which it is suggested should be treated in a broad and dignified rather than in a florid manner. This statement is, at least, satisfying, as it allays any doubt as to the intentions or proclivities of the assessors on this point, though the gentlemen selected to fill the onerous post are not likely to influence strongly nor prejudicially the tastes of competitors, as would have been the case if other eminent architects had been chosen whose sympathies are more pronounced.

The external fronts are to be of stone, and the freestone quarries of Dunmore, near Stirling, have been suggested as affording a hard and compact freestone somewhat harder than good Portland stone. An approximate estimate is to be sent in with each design, to which adherence will be required. Not fewer than six, or more than ten, of the preliminary designs will be selected, the authors of which will be invited to enter into the final competition. Each of these will be paid the sum of £150 towards his expenses, providing he comply with the final conditions prescribed. This is a small and inadequate payment for even a sketch-plan, and might have been increased to £200. Condition 27 is questionable. It makes it imperative that, until after the final award has been made and officially published, no drawings or descriptions of any of the designs are to be sent to any member of the council or to the public, nor is any exhibition of the designs to take place. Why this strict exclusion of the public or the press is to be enforced is not very evident, nor do we think the prohibition of private canvassing will effectually debar those who resort to such dishonest means of obtaining notice; and to enjoin that no canvass of magistrates or assessors is to be made seems almost unnecessary. We merely add that the preliminary designs are to be sent in on the 30th day of November next. We hope for a better result for all concerned than last year; but, as may be gathered from our preceding remarks, we cannot remain blind to certain defects in the new conditions, which may produce undesirable consequences.

THE ST. PAUL'S ECCLESIOLOGICAL SOCIETY AT ROCHESTER.

THE second session of St. Paul's Ecclesiological Society was closed on Saturday by an all-day visit to Rochester. Between forty and fifty members took part in the excursion, which proved a very interesting and pleasant conclusion to the year's meetings. On leaving Rochester-bridge Station, the *Guildhall* was the first place visited. It is a red-brick and tiled building, erected in 1687, and containing in the principal apartment (the magistrates' room) some panelling, a good coved and plastered ceiling, and a series of eleven full-length portraits of local celebrities, from Sir Stafford Fairbairn, William III., and Queen Anne to the late Sir F. Wykeham Martin, M.P. The *Corn-hall*, a little further up the High-street, has a clock, the gift, as an inscription sets forth, of Sir Cloudesley Shovel, 1706; the present exchange was built from the designs of Messrs. Flockton and Abbott, of Sheffield, in 1871, and is lofty, well lighted, and of pleasing proportions. The *House of the Six Poor Travellers*, immortalised by Dickens, awakened much interest. It is a charity founded by will by Richard Watts, 1579, by which six poor travellers, not being rogues or proctors, receive gratis for one night lodging, entertainment, consisting of $\frac{1}{2}$ lb. meat, 1 lb. bread, and $\frac{1}{2}$ pint of beer, and in the morning 4d. each. The building is solidly constructed, of stone, in two stories; the front-rooms are the curator's apartments, and behind these are, on each floor, three cubicles, white-washed and well scrubbed, and provided with a bed; the upper tier is reached by a narrow gallery. The building was modernised by the substitution of plate-glass for lattice windows, and otherwise restored, about four years since, and the books showed that the charity is constantly made use of. On the High-street several picturesque half-timbered houses were seen, the finest example being a group on the north side, illustrated by a sketch from Mr. Owen W. Davis's pencil in the BUILDING NEWS for Aug. 18, 1871. *St. Bartholomew's Chapel*, on the boundary line between the High-streets of Rochester and Chatham, was seen under the guidance of the Rev. John Bailey, the hospital chaplain. The building consists of small nave with north aisle, north transept, chancel, and apse, and from the exterior gives no promise of archaeological interest, as the west front, and bell-turret, the south wall, and the tiled roofs are all painfully modern and fresh-looking. The Rev. J. Bailey explained that the chapel was founded as an adjunct to lepers' hospital by Bishop Gundulph, but was built by his successor, Bishop Ernulf, both of whom were greatly concerned in the building of the cathedral, the actual work being carried out by a monk, Hugh de Cliffe. When leprosy ceased to exist, the hospital which adjoined on the north was pulled down, and from about the time of Elizabeth the chapel was sub-divided into lodging-houses, and there was every prospect of its destruction. About 120 years ago it was restored to its old uses, and a few years since the late Sir Gilbert Scott, R.A., prepared a report on the building, in which he stated reasons for believing that the flat wooden lintels to the deeply-played windows on south side were the original ones of the 11th century, and were devised in order to leave space for the lean-to building, of which there were clear traces on this side, and in which it was probable the lepers gathered to hear the service. The chapel was partially restored under Sir Gilbert's care, the old carved chalk-stones found in the windows, &c., being replaced and used as guides for the new stonework. The semicircular recess at eastern end was found to be a true apse, domed in concrete, and formerly had a stone bench round it as in basilicas; this apse had since been decorated in colour by a member of the congregation. The old cottages by which the chapel was built round were removed, when it was seen that the window-recesses had been used as cupboards, bearded upon the interior of the chapel, and that a stove projected into it. The sedilia, having Purbeck shafts, had been opened out, and an organ, rather too large for the building, was put into the north transept; the north aisle was entirely modern. Further restoration was contemplated, including erection of permanent vestry, and also the laying out of the grounds. The funds having increased, a new and large hospital of St. Bartholomew was built in 1862,

on the adjoining hill-side. The whole of the afternoon was spent in

THE CATHEDRAL.*

The party were received under the central tower by the Dean, who welcomed them to the place, remarking that though Rochester was neither one of the largest nor most beautiful of our cathedrals, it would be found to contain a great deal of Late Norman and Early English work; but, curiously enough, very little of the intervening work from the 13th to the present century.

The Rev. Canon Scott Robertson, of Canterbury, said the Saxon history of Rochester, from its foundation and onwards, was better known than that of any other see, but no pre-Norman remains were known to exist, unless the theory of Mr. J. H. Parker, C.B., was admitted, that the massive pillars with unchanfered caps at the west end of the crypt dated from before the Conquest. Personally, he believed they must begin with the work of Bishop Gundulph, who held the see from 1077 to 1108, and who also built the White Tower of London, and Malling Tower, near Maidstone. Here, at Rochester, he built a complete church, of which the outer shell of nave had been shown by Mr. Irving, the clerk of works under Sir Gilbert Scott, to remain, in great part, as high as the triforium level. Gundulph was succeeded by Ernulf, who had been Prior of Christ Church, Canterbury, and then of Peterborough, in both of which places he carried out great works; here he carried forward the nave, built the former chapter-house, and from architectural evidence we believed that he built the present rich west front during his occupancy of the see, 1115-20. In 1137-8, the church and monastery adjoining were so burnt that the monks were dispersed, being without shelter, but they returned ten years later, and the Bishop Walter, of that time, greatly pushed forward the work of repairs. The chronicles again contained a most puzzling statement, for, in 1177, we were informed, a second fire reduced the church "to a cinder." The statements appeared to show that the place was utterly consumed; but the members had only to look around them on the rich Transitional Norman work of the nave to see that this must be accepted with a certain amount of reserve. There was, at all events, an extensive restoration necessary, of which Mr. Irving found numerous traces in the south transept, but which he was unfortunately obliged to sweep away. In the nave down which they were looking many peculiarities were noticeable; for instance, upon each pier there was a vaulting shaft carried to level of the triforium floor, but although there were traces of the upper portion of these shafts having been removed, the intention of vaulting the nave with stone was never carried out. The triforium gallery, once very perfect, had been blocked up by Sir Gilbert Scott, who considered this action necessary to insure the stability of the fabric. The tympana of the triforium openings were filled in with varied and exceedingly rich diapering and shields, &c., to which there was no parallel, except some carving at Canterbury, known to have been done about 1236, and this convinced the speaker that the ornamentation was of a much more recent period than Ernulf's constructional work. The clerestory above the very appropriate open-timbered roof, and the great eight-light western window, were additions of the fifteenth century to the nave. Not only was this roof once richly coloured, but the whole of the triforium surface was formerly picked out in green, red, and yellow. If they examined the aisles, they would there find that on the north much more elaborate than that on south side, and the eastern bay to north was blocked up by a huge mass of masonry. The reason for this was that the north aisle was reserved for the use of a parochial congregation from the time of Gundulph till 1121, when a church was built parallel to, and a little north of, the cathedral, a church which was rebuilt as we now saw it in 1521. The blocking up of the eastern bay of nave was in order to shut the parochial service off from that of the cathedral, and also to furnish space for the sedilia, &c. Even after the new church was built the parochial clergy had the privilege of bringing their weekly procession

of the Host through the south-east door of their church, across the cemetery-ground, and entering the cathedral by a door in the north transept, proceeded down the north aisle to a doorway now blocked up near the north-west angle. In 1201 a pious Scotch baker named William was murdered by his servants while travelling at Chatham; the monks of Rochester gave the body burial, and found it a very profitable undertaking, as immediately afterwards miracles began to be performed at the tomb, and streams of wealthy pilgrims were drawn through the city. A shrine to St. William was erected in the south-east transept, and with the pilgrim's offerings the two eastern bays of nave, the great transepts, and the choir were rebuilt. The new work was of a beautiful type of Early English, in which Purbeck marble shafts were freely used. The new work apparently began, according to the chronicles, with the great north transept; the new choir was opened, they knew, in 1227, but was not completed till twenty years later. He ought to have mentioned that Gundulph had built a tower on the north side to east of transept, of which ruins still stood; while, on the south side, beneath the floor, Mr. Irving found foundations of a sunken tower. These Mr. Irving thought to have been towers of defence in connection with the city wall, which he believed crossed the cathedral site, just to east of central tower arch; but the speaker did not concur in this theory. The records stated also that in 1343 Hamo, of Hythe, caused the campanile to be raised with stone, timber, and lead, and put four bells in it, and this upper part of tower, and the wooden spire which formerly surmounted it, was, they knew, removed by Mr. Cottingham for the present not altogether satisfactory tower rather more than half a century since. Three eastern bays of south aisle to nave, they would see, had been greatly extended, so as to form a chapel of St. Mary. This adjunct, which was first mentioned in 1399, formerly had a stone bench running completely round it, so that the only entrance was at the east end. He ought also to mention that they would find in the choir-stalls some of the earliest woodwork known to exist; it was of plaie, but good, Early English character, and dated from about 1227.

Mr. J. T. Micklethwaite, F.S.A., of Westminster, referred to the work of restoration and exploration so long carried on by Mr. Irving, and more recently by Mr. St. John Hope. The division of the Saxon and Norman church into a monastic and secular portion, as at Rochester, was a very usual arrangement, but one which almost invariably led to clashings of processions and strife, and frequently resulted, as here, and at Winchester, Westminster, &c., in the erection of a small church, close to the minster. This parochial adjunct, and the great cemetery, were nearly always to north of the minster, the reason being that the monastic buildings being on the sunny side, the chief approach for lay persons was on the opposite side of minster, and in order that these people might offer prayers for the dead the burials were made on that side. Since the monks, as part of their duty, said prayers for deceased brethren, this publicity was unnecessary in the case of their graves, and they were accordingly buried at the east end of the minster. The prevalent notion that the monks used the cloister garth for burials was erroneous. They often buried close to the chapter-house entrance, and so the east and south walks of cloisters contained the earliest graves known to exist, but the western and northern walks were not so used till much later times. In the 13th century the practice of burial in the church itself commenced. He believed the parochial altar, in the north aisle, before St. Nicholas' Church was built, was on west side of the two Early English bays now forming the eastern part of the cathedral nave, and a choir screen, like that still to be seen in St. Alban's nave, crossed the nave at this point. Upon this screen it was usual to place, not a rood or cross, but the small organs then in use, so that the custom of setting up an organ at the tower crossing had Medieval precedent. The detailed history of this building was exceedingly complicated, not only on account of the great fire said to have destroyed the fabric, but from which a great deal of earlier work appeared to be still preserved to us; but because of the many attempts at ornamentation or enlargement begun in many parts by successive designers, and presently allowed to drop, apparently be-

cause funds failed. When sufficient money came in, the fashion had changed, and a new scheme was in turn commenced and abandoned.

Mr. Micklethwaite then conducted the visitors throughout and round the cathedral, offering explanations at the leading points. Beginning with the crypt, which extends under most of the choir, he showed the earliest work now left in the western portion. The eastern part of crypt consists of six alleys of comparatively slender columns, with Early English bell mouldings to caps. On the north side are a great number of fragments of carving found during the progress of restoration of the cathedral above, and including some censuring angels, and the Virgin Mary being crowned by her Son—work of about 1310—large portions of an Elizabethan tomb, some Late tabernacle woodwork, &c. The carved stones are arranged on boards, quite unprotected from the depredations of unscrupulous visitors, and Mr. Micklethwaite, in commenting on this seeming want of care, mentioned that a lady who recently visited the cathedral, wishing for a relic, carried off the head of a figure from this crypt museum in her mouth. Returning into the cathedral, attention was drawn to the Early English architecture of the great transepts, and the party passed into the choir, where the remains of the 13th-century woodwork were closely examined. The old desks are marked by trefoiled openings carried by very low shafts, not more than 18 in. high, including heads and octagonal bases; greater height was then unnecessary, as they were not used for books. We owed the preservation of these unique examples to the fact that they were encased by the 15th-century builders and used as a ledge; during the last ten years they had been opened out, but he regretted that in so doing they were removed from their original positions. On the previous day he found in a coalcellar in one of the neighbouring houses a piece of wood, which although rotten, could be preserved and replaced as one of the elbows. The singular diapered pattern on the walls was in glaring colours and not very harmonious to our eyes, but was a portion of the original decoration. To the east and north of the presbytery was seen a 14th-century bishop's monument, in alabaster, richly gilt, much after the fashion of the De Valance tombs at Westminster Abbey, although not in Limoges enamel; the deceased is represented on the effigy as clad in the chasuble, without aumbray, but with rich dalmatic, amiss, and maniple, and having a pastoral staff with napkin attached. At the east end, Sir Gilbert Scott's restoration was freely criticised by members, especially the lowering of floor, which was stated, however, now to correspond with the old tile matrices; the want of breadth in the new reredos and high altar, which Mr. Micklethwaite said, seemed to be set too far eastward, judging from the position of the sedilia. On the north wall, close to the east end, remains a very perfect stone lavatory. On the high altar were seen a pair of candlesticks of the time of Charles II.

The members then went up into the tower, where in a treasury they were shown numerous silver-gilt articles of plate, &c. The principal patera of silver-gilt was pronounced by Mr. Micklethwaite to be a domestic fruit-dish of the 16th century, and the chalice to be not later than 1530, the hexagonal stem and base indicating a survival of a pre-Reformation form. It was stated that the existence of this old plate was not generally known, and that it was never used. Returning to the great south transept Mr. Micklethwaite said that the beautiful doorway on the east side was not originally the chapter-house entrance although now known by that name, and leading to the chapter-house; but it was the monks' principal approach from the cloisters. The elaborate carvings on the sides had been rendered unmeaning by some restorer; originally, they showed female figures, one representing the Synagogue with the Law slipping from her hands, the other, the Church holding a model church and a cross, but the latter statuette had been recarved with beard and mitre, and now did duty as a bishop. Passing through this doorway, the present chapter-house, an oblong chamber of no great interest, was seen; and the visitors descended a flight of steps into a garden, made over the western portion of the original chapter-house. It communicates with the cloisters by three richly-treated Transitional arches now blocked up; and upon the walls are remains of intersecting arcading. Returning westwards, the

* The west portal of Rochester Cathedral was illustrated in the Building News for June 24, 1870. Sketchbook Series No. 33), and the new stalls in nave, executed from Mr. J. P. Seldon's design, on Oct. 21, 1852.

remains of the east walk of cloisters, a series of arcades of elaborate 12th century character, were examined. A walk round the cathedral and a somewhat cursory examination of the Prior's and College-yard gateways to north and south of the Close, completed the inspection, which had been of an exhaustive character. *St. Margaret's Church*, next seen, under the leadership of Mr. Ford, has been rebuilt, with the exception of the 14th-century west tower, in a pseudo-Italian style, and was restored about forty years ago by Mr. Hussey, and more recently by Mr. Gordon Hill. The most interesting feature is a so-called palimpsest brass, engraved on both sides with a portrait of one Thomas Codd, vicar of the parish, who died in 1440; it is inclosed in a modern oak frame, locked up, and is placed on the east wall of nave. A short visit to the *Castle** concluded the day's proceedings.

PRACTICAL NOTES ON PLUMBING.—VI.†

By P. J. DAVIES, H.M.A.S.P., &c.

SOLDERING BRANCH JOINTS.

IF you require to solder small branch joints without irons, fix them as at Fig. 22, Chap. V., in which you will see a block, B, placed under the joint (which must not be too high), the object being to block up the joint so that you can wipe clean round the bottom of the same. Neither must it be too low, but just sufficient to keep up the heat. A good height for $\frac{1}{2}$ in., $\frac{3}{4}$ in., and 1 in. joints is a piece of wood $\frac{1}{2}$ in. by $\frac{1}{2}$ in., and from 4 in. to 6 in. long, or, in other words, the bottom of the solder-line E (Fig. 22) should be kept up from the floor, &c., $\frac{1}{2}$ in. of an inch (see end view of Figs. 29 and 30), one a soil-pipe, the other a lin. pipe; this will answer for almost any joint. After this, proceed thus: Take the solder (two of lead and one of tin), and with your splash-stick splash all round the top part of your joint (Fig. 22) at A P, also round F D; keep at this as fast as it will hang together until you have shaped the joint, or as well as you can with the splash-stick; the heat may be kept up by splashing an inch or more beyond the soiling. Now, when you can feel the lot to be in a semi-fluid state, take the cloth (which your mate has made hot over the solder) in your left hand and wipe all round the top part and left-hand side of the joint from P to K, then round the bottom and centre part as at G; bring this round to the line F K; next take the cloth in your right hand, and as "quick as thought" wipe the top part of the right-hand side, or round P C K; then J G L, also the bottom, and then as a finish wipe down from K L, and off at F. If you work quickly, you may do it without showing the marks of your cloth when coming off.

Should your solder be rather coarse, it would be best to use yourself to first wipe clean round the top part of your joint from P C K to J G L, and finish as you go down the joint. By the bye, you may notice one very peculiar phenomenon in joint-wiping, viz., that the solder sets first round the top part of branch joints, which at first sight appears strange, and you will probably think that because the heat ascends that the top solder is the hottest part, but this is not the case; the truth is, the lead has taken up the heat, and the body of the heat is in the centre of the joint. For this reason always wipe the outer edge first, *unless you can do all at once*.

Fig. 27. This diagram shows the joint finished, but cut in half at the solder B G, as also the bottom part of the pipe. This is as the solder should be when finished, i.e., even in thickness, and strongest across the joint at B.

Fig. 29 shows the end view elevation of the joint and the solder on the sides; that is, true and round where the strength is required. It also shows the blocking up of same ready for wiping.

Fig. 30 shows that instead of a block being put under the bottom of the pipe, two bricks or other packing (a few pieces of sound boarding here are handy) are required on the top of these. Place two or three thicknesses of newspaper as shown at H H, tuck it between the side of the pipe

and packing as at L L, in this diagram, to prevent the solder from running through.

Let us again examine Fig. 27. This is a joint made on the slope. When wiping it splash on the solder as you did Fig. 22, but when

wiping, first shape the back part from P to D. When the pipes lie at such an angle that you

cannot get the fingers and cloth between them, wrap a piece of fustian or old cloth round a

small stick, a suitable size for going between the pipes and wiping this part; then finish the two sides and come off from F to B, keeping this rounded as shown by the dotted lines. Of course, the sides of this joint should appear like those in Figs. 27 and 29.

WIPING BRANCH JOINTS—HORIZONTAL INTO UPRIGHT.

Fig. 31. This joint can be made by an expert workman in its place, but three-fourths of the plumbers cut the upright pipe in order to bend it, so that they may make it on its back. It, however, should be made as follows:—Having prepared the joint as other branch joints, fix the collar, or board blocks, as shown at H K, about $\frac{1}{2}$ in. below the shaving line, then splash your solder well up the soiling and prepared part of the joint, get your solder to the usual working point, and then with a warm cloth wipe from about midway on the other side of the joint, and up over the top L F to about E G C, taking care to keep it round; place your hand under the branch and work the joint from where you began, round the bottom and up to C G E, and off at E. The art of wiping this, as all other joints, is *quickness* without weakness of the nerves. Try one or two by way of practice, and you are sure to win.

I give this hint to these who have declared it to be impossible. Many good plumbers wipe their joints without shifting their cloth from one hand to the other, but I prefer to use both hands.

(To be continued.)

A RAILWAY AT LESS THAN £5,000 PER MILE.

MESSRS. Cornelius and George Lundie, civil engineers, Cardiff, have issued a pamphlet showing how a railway could be made, suited to the requirements of Central Northumberland and the North-Eastern corner of Roxburghshire, at a cost of less than £5,000 per mile, with a prospect of a fair return of profit on the outlay. The line of railway they propose is from Rothbury to Kelso, by way of Thropton, Lorbottle, Whittingham, Clanton, Wooperton, Lilburn, Middleton, Wooler, Akeld, Kirk Newton, Kilham, Paston, Yetholm, Primside, Morebattle, Kalamouth, and joining the North-British Railway at the Heiton Sidings at the south end of Roxburgh Bridge, and probably to traverse the existing North British Railway by means of a mixed gauge to the Kelso Station. The distance from Rothbury to Heiton Sidings, by this route, is about 47 miles, and to the Kelso Station nearly 50. Such a railway would serve a district having an area of about 200,000 acres, of which nearly one half is inclosed and arable land, and the remainder upland pasture. They estimate the annual value of the traffic at £24,500, of which £5,000 is put down under the head of passengers, parcels, and general merchandise. Assuming that 50 per cent. of the gross earnings will cover the working expenses, £12,250 would be applicable to dividend, which, capitalised at 5 per cent., will give £245,000 as the amount that may safely be expended on the railway. They believe that a single line of railway, on the three feet gauge, with gradients not steeper than one in fifty, and with fairly easy curves, well laid with strong steel rails and suitable sleepers, could be made at a price that would fulfil the required conditions. The financial limits, they urge, indicate that a single line on the three feet gauge would prove a self-supporting and fairly profitable concern, and, on the other hand, it does not appear to them that anything greater ought to be attempted. No gradient steeper than 1 in 50 would have to be encountered by the working trains; and locomotives of the greatest power that could be worked on a three-feet gauge might be used, and run at a speed of 25 miles an hour. A break of gauge, they say, is not to be desired; but in this case the question seems to be—Will the district accept a three-feet railway with this disadvantage, or will the inhabitants be satisfied to remain for an indefinite period without a railway of any kind, in the hope that posterity may by some means be supplied hereafter with a railway of the ordinary gauge? The estimated cost of the line is put down at £4,000 per mile, including land.

* The interior of Rochester Castle was illustrated in the *Building News* for Feb. 11, 1879, as No. 18 of the Sketchbook Series, from a drawing of Mr. E. Skewitt.

KIRKWALL CATHEDRAL.

SHORTLY after the transfer of the Orkneys and Shetlands from the Danish to the Scottish Crown, Kirkwall Cathedral was handed over by James III. to the Corporation of Kirkwall as trustees for the due preservation and maintenance of the fabric; and, about the year 1814, a certain Mr. Meason, by his will, mortgaged a sum of money to provide the funds for the necessary repairs that might, from time to time, be requisite.

The income arising from this fund has been periodically applied by the trustees, with the sanction of the Corporation, and, as many people think, not always in the most judicious manner.

Several years' income having accrued, the trustees now propose restoring some four windows on the south side of the nave which have been partially blocked up for years, and the stones for this purpose have, so Mr. J. R. Jador, of Wick, says in the *Scotsman*, been already dressed by the local stone-cutters, in accordance with plans drawn up by a local builder.

Many people in the district object to the Cathedral being tampered with any further, except under the advice of some architect competent, from previous experience obtained in connection with ancient ecclesiastical buildings, to form an opinion as to what would be *really judicious and fitting restoration*; but the Town Council and trustees seem inclined to stand on their legal rights, and to consider that they are the best and most fitting judges of what is necessary.

Kirkwall Cathedral is not merely the property of the burgh of Kirkwall, the Orkneys, or even of the United Kingdom, but of the whole civilised world; and the idea of the average baillie, minister, and kirk elder resolving themselves into a committee of taste on the restoration of one of the two remaining cathedrals of Scotland is something too horrible to contemplate. Nothing should be done, either in the way of restoration or even of repair of a building in which, as Sir Henry Dryden remarks, no less than five different styles of architecture can be traced, except under the advice of one of the architects of one of the English Cathedrals, as, with all due deference, no Scottish architect, thanks to the iconoclastic zeal of the 16th century, can be fitted to give an opinion on such a question.

Perhaps, when the attention of the public at large is called to the matter, any further mutilation of the beautiful "stone minster," erected by rhyming Rognvald to the memory of his uncle the holy St. Magnus, may be prevented, and some steps taken to insure for the future the due preservation of this glorious memorial of these hardy Norsemen to whom the English-speaking races are indebted for some of their best and sturdiest characteristics.

The proposed window restoration may be all right; but what most persons in the Orkneys best fitted to form an opinion on the subject feel is, that nothing should be done with so important a historical monument as Kirkwall Cathedral, either at the present time or in the future, except under the very best professional advice.

BRISTOL AND GLOUCESTERSHIRE
ARCHÆOLOGICAL SOCIETY.

THE members of the Bristol and Gloucestershire Archæological Society on Tuesday began their meeting at Clipstow. The headquarters is the Beaufort Arms Hotel, and in the meeting-room a temporary museum was opened. Soon after noon the local committee received the society, and the opening meeting was held under the retiring president, Mr. J. E. Dorington.

Sir John Maclean, who was at this point introduced as the president of the meeting, then delivered his inaugural address. He gave an elaborate description of the Forest district in which the meeting was held, and concluded with some general observations on restoration as follows:—I have alluded to the progress which archæology has made within the time of the existing generation, and I have called attention to the vast and valuable increase of historical knowledge derived from archæological discoveries. I must, however, confess that it has not been altogether gain. As the number of persons who take an interest in our ancient monuments increase, the monuments themselves gradually disappear—not

altogether from natural decay—not by wanton destruction—not by injuries inflicted without evil intention by those who are ignorant of their value—but from other causes. 1st, That very progress to which I have alluded, which spares nothing which lies in its way; 2nd, Through the active, though ignorant, zeal of those who desire to uphold them; and 3rd, By the too lavish use of them by too earnest inquirers. Of the first class, are the ancient works of antiquity which have been destroyed in making railways and other similar works. It was only the other day that I heard that the Dock Company at Gloucester had purchased the site and ruins of Llanthony Abbey for the purpose of making a dock. Of the second, I may more especially allude to what is called the "restoration" of our churches. I verily believe that our ancient parish-churches have suffered more within the last thirty years from mis-called "restoration" than they suffered from violence and neglect during the preceding 300 years. And what has been the cause of all this? I believe one of the chief reasons has been the hurry with which the thing has been done. There has been a perfect mania for the restoration of churches. Doubtless from past neglect a large number required very extensive repairs, and if the works had been limited to that no fault could have been found—or if the restoration had been truly such, if actually needed, instead of violent alterations and fancied improvements, no objection could have been taken. But what has generally been the course adopted? The parish of A has had its church "restored." The parish of B must not, of course, be left behind. Consequently a resolution has been adopted that the church requires restoration. An architect is called in,—it matters not whether he has the slightest knowledge of ecclesiology, and I am very sorry to say few architects have—funds are raised somehow or other, the church is closed, and the whole work must be completed within the year. The architect likes a clean, neat job, and he is paid by a commission on the expenditure. Everything he does not understand is swept away, even the monuments, monumental brasses, and grave-stones are cast aside to admit of the passages being all paved with Minton's tiles. In or about the time limited, everything is turned out speck and span new—the grand old oak roof is replaced by a neat one of deal, the carved bench ends are removed to make way for uniform deal seats, all the plaster is taken off the walls and the rough rubble masonry pointed, which was never done in ancient times, for if the old architects used the natural stone, either in walls or vaults, it was carefully dressed to an even surface for the reception of colour. The mouldings are simplified by being scraped down, and even the mailed effigies of ancient knights or barons, recumbent on altar-tombs, are often ruthlessly pecked over, and every characteristic destroyed, for the purpose of making everything neat and clean. To church-restorers, if there should chance to be any one here who contemplates such a work, I would say: be slow to begin and not over-hasty in going on. One of the most satisfactory restorations I know of was that of a parish-church in Devonshire. It was done, bit by bit, as they could obtain the money in the parish, which was chiefly collected at the offertories at the harvest festivals. All the work was done in the best manner and with the best materials, and it is no drawback to say that the execution of the work extended over 17 years. My advice is, remember that restoration consists in replacing the building in the same condition in which it was when it left the original architect's hands, and if the building be of different periods, or styles of architecture, when that particular work was executed. Remove nothing ancient from the position in which you find it, unless some other "restorer" should have been before you, and misplaced it, and if anything, such as a roof-screen, has been destroyed, renew it, if possible, in the same character as the original one. Do not fancy that the architect whom you employ is more skilful than his ancient brother, and therefore allow no improvements. The extent to which so-called restorations have been carried, and the manner in which they have been executed, make one feel sick at heart. It has now become a rare treat to find an ancient unrestored church. A society has recently been formed for the protection of ancient monuments. I am not a member of it. As regards our ancient churches it has been formed 10 years too late. The mischief has been

done, and it is irreparable. But there are other monuments which require a watchful care. I am shocked to say there is even a proposal to "restore" Stonehenge. On the third point I dare to say a few words, and I do so in the presence of some of my friends who will I hope forgive me. The most interesting and instructive of our ancient monuments are the pre-historic tumuli. Their exploration has added much to our knowledge of the characteristics and habits of the primitive races of this and other countries. But I would humbly ask, Have we not gained from these ancient burial-places all that they can reveal to us, and is not the time come when we should restrain our hands in this direction and seek some other sources of information? Few, comparatively very few, now remain unspoiled, and those few, in my opinion, should be carefully protected and preserved as evidence for future generations. I well know how strong is the inclination, how insatiable the desire, how fascinating the work of exploration; nevertheless I would earnestly say, Waste not! Stay your hands!

Soon after the company left and proceeded to Clipstow Castle, where Mr. G. T. Clark, of Down-lais, gave an address on the castle. A carriage-excursion was then made to Beachley and Sedbury Park, in order to inspect Offa's Dyke, upon which the President made some remarks.

In the evening there was a meeting at the Beaufort Arms Hotel, and papers were read.

PRESERVATION OF TIMBER AND
HOUSE BASEMENTS.

MINERAL solutions forced into the fibres of wood are found to arrest the decay of timber by impeding decomposition by wet rot, and also to prevent the growth of the fungi peculiar to dry rot. A weak solution of corrosive sublimate, or of nitric acid, has been found of service, after which the timber may be painted with white-lead and oil. Timber, such as wall plates, ground joists, and sleepers near the ground, ought always to be creosoted or coated with a solution of coal-tar and fish-oil mixed with finely-powdered clinkers from a forge. All these preventive means are, however, useless in arresting decay under certain conditions. If the timber has not been seasoned or desiccated, the solutions will not enter, the pores being previously occupied by the fermenting juices, and the process, therefore, will not be effectual. Again, if the joists of ground-floors are not ventilated it is of no use to apply remedial measures after the mischief has been done. There are primary conditions, but which, singular to say, are unheeded by nearly all the builders of small tenements around our large towns. The consequence is that few basement floors last more than a dozen years without showing signs of rapid decay.

The building of basements or stories below the ground-level, as most of the breakfast parlours about London are built, prevent, it is true, the use of air-bricks, but then why should builders still persist in having wooden floors in such situations? People like wood better than cold stone or even cement with concrete below; hence there is a difficulty in doing away with wooden floors. But blocks of solid wood can be laid on concrete; and these make a comfortable floor for the feet, and may be repaired at less cost when they do wear out, which is not often. Many buildings have basement floors of these blocks; but it is surprising the average builder is so long getting out of the rut in these matters that he must see it used repeatedly by enterprising builders before he ventures to make the change. A boarded floor on joists of shabby Swedish timber, with scantling only enough for ceilings, or a cold damp floor of cement or stone laid on rubbish, appear to be the only forms of flooring known to the majority of builders of our smaller houses.

The death is announced of Mr. James Boyle, C.E., for 14 years the secretary of the Public Health Committee of Dublin, and through whose energy many of the recent sanitary improvements in the city have been carried out, "as effectually as the resources of the department and the powers given by the Public Health Act have permitted," as one of the Dublin newspapers in an obituary notice remarks. A vote of condolence with the family was passed at Tuesday's meeting of the Dublin Corporation.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

THE BRITISH ARCHÆOLOGICAL ASSOCIATION'S CONGRESS will this year be held at Malvern, and will be opened on Monday, August 22nd, by an inaugural address from the President, the Dean of Worcester, Lord Alwyne Compton, to be followed by an examination of Malvern Priory Church, founded c. 1080, and "presenting in its mixed styles of Early Norman and Late Perpendicular many features of interest and beauty." During the Congress week at Malvern, excursions will be made by carriages and railway to Birtsmorton Court, a moated manor-house of the 14th century; the adjoining church; "Payne's" Place, where Margaret of Anjou took shelter; Tewkesbury battle-field, the restored Abbey Church and old houses at Tewkesbury, Seven-end Manor House, the Rhydd, Madresfield-court, Pickersleigh, a fine specimen of Jacobean and earlier work; Bosbury and Ledbury Churches, Wall's Hill Camp, Much Marcle and Kempeley Church, the latter having some good frescoes on its walls, discovered a few years since; Kidderminster Church, Warshall (close to Habbersley), Bewdley, Ribbesford, Areley Kings for Manor House, &c., Redstone Hermitage, and Astley Church, thence to Moor Hall, by the invitation of Mr. John Brinton, M.P., who will kindly take charge of and conduct the party on the Kidderminster day; Little Malvern, Herefordshire Beacon and Midsummer Camp, an ancient British fortress of large extent; Branshill Castle, a Norman stronghold; and Eastnor Castle and Park, by the kind permission of the Earl Somers. It is also proposed to visit in the following week Worcester and Cheltenham. Meetings will be held every evening in the School-room of the College, by the courtesy of the authorities, at 8.30, for the reading and discussion of papers, after the opening day. The hon. secretaries are Mr. E. P. Loftus Brock, F.S.A., 19, Montague-place, Russell-square, and Mr. W. De Gray Birch, F.S.A., F.R.S.L., British Museum, Bloomsbury, W.C.

BOURNEMOUTH FIELD CLUB.—We are glad to announce that the above society has recently been formed here, the Right Hon. Earl Cairns being president. The inaugural excursion took place at Christchurch, Hants, on the 25th of last month, when the Priory Church and Heron Court, seat of the Earl of Malmesbury, were visited. On Thursday, July 14th, the second excursion of the society took place at Wimborne, Dorset. The first place visited was Dean's Court, through the kindness of Lady Gibson Craig. The members were met by Mr. Craig and Major-General Maclean, who conducted them over the mansion. The windows, containing a large quantity of fine old glass (temp. 1550) chiefly armorial bearings, were much admired, though there was some difference of opinion as to the families to which they belonged. Dean's Court marks the site of the College, a part of the present building being formerly the Dean's residence. The house was considerably added to by Sir William Hanham, third Baronet, in 1725, and contains a complete series of portraits of his family from the time of Elizabeth. Leaving the grounds, the members noticed the old fish-ponds. On reaching the Minster, the members were received, in the absence of the vicar, by the Rev. J. Paget, Mr. W. Fletcher, and Churchwarden Hayter. The hon. secretary, Mr. Mills Robbins, read a paper on "The Early History of the Church." Mr. Fletcher pointed out the chief features of interest in the church, and Mr. Hayter exhibited the ancient documents. Subsequently, at the Vicarage the members were entertained by Mrs. Trotman, after which a hasty visit was paid to the Lepers' Hospital and Chapel, dedicated to God, St. Margaret, and St. Anthony, when the Rev. J. R. Pretymann read a short paper on "The Hospital," and the Secretary exhibited a copy of some of the 15th-century wall decorations.

ROYAL ARCHÆOLOGICAL ASSOCIATION OF IRELAND.—The quarterly meeting of this association was held for the first time in its history at Enniskillen on Tuesday week, and was opened with an address from the President, the Duke of Leinster, in which he referred to the numerous objects in the neighbourhood of the town in which they were met. Mr. W. J. Knowles, of Cullybacky, Antrim, sent up a large collection of ancient Irish beads, of glass, stone, jet, serpentine, sandstone, and quartz, and one of rock-crystal,

accompanied by a descriptive letter and specimens of the fictitious articles often sold to unsuspecting English collectors. Mr. E. Atthill, of Ardvarney, showed specimens of ancient pottery from Indian mounds near Lake Sturgeon, Canada. The Rev. James Graves, hon. secretary, showed photographs of a fourteenth-century processional cross bearing an inscription stating that it was made by "O'Connor of Kerry, the head of his nation." It is identical in size with the famous Cross of Cong, now the chief relic in the museum of the Royal Irish Academy. Mr. Graves also mentioned to the members that the inscription on the Dunvegan Cup, mentioned by Sir Walter Scott, had recently been deciphered, and stated that "Katherine McGreynell, wife of John Macguire, the Prince of Fermanagh, had me made in the year of our Lord, 1493." Mr. Marcus Ward read a paper on the varied fancy exhibited by early Irish artists, and showed a rubbing and coloured tracing from the Hiberno-Romanesque scroll ornamentation in the ancient Church of Maghera, Co. Londonderry, and contrasted therewith the engraving of the same scroll-work given by Lord Dunraven in his work on "Irish Ecclesiastical Remains," proving the inaccuracy of the latter. Other copies of early sculpture and illustrated MSS. of the district were also exhibited.

COMPETITIONS.

MANCHESTER.—In a limited competition for the Manchester offices of the Commercial Union Assurance Company, the design of Mr. Charles Heathcote, architect, Manchester, has been chosen. The other competitors were Messrs. Mills and Murgatroyd, and Messrs. Salomons and Ely. The cost is limited to £7,350.

NASHVILLE, TENN., U.S.A.—Designs are invited for a block of buildings to be known as the Watkins Institute, to be built at Nashville, Tenn. The plan contemplates a block of stores for business purposes, on Church-street, consisting of four stores, with a basement under each of 10ft. clear, and two stories above the stores, the first of 14ft. and the second of 12ft. in the clear. The stores themselves are to be 16ft. clear. Through the centre of this block a hall is to run, 12ft. wide, for the purpose of reaching the public buildings in the rear, presently to be noticed, and also for the purpose of reaching the second and third stories of the block by a stairway at the rear, inclosed and covered in, with suitable openings. The front of this block is to be of stone. The side on High-street, as well as the body of the building, will be of brick. In the rear of the front block, at the distance of 20ft. therefrom, is to be erected another building extending across the lot 75ft. front by 112ft. deep. The first story of this building is intended for a public library and reading-room, and must be not less than 18ft. in the clear; the second story is intended for a public hall and lecture-room, and will be not less than 25ft. in the clear. Access to the second story will be had through the hall of the front block as above described, and also by a circular stairway in the lower front corner of the building on High-street, and with such other means of ingress and egress as will make the building safe against fire. The front of the building on High-street is to be of stone, and that part of the front containing the circular stairway may be run up above the roof into an ornamental tower. The cost of the front block and of the building in the rear, both, is not to exceed the sum of 80,000 dols. Plans may be drawn to a scale of 8ft. to 1in., and such details to a larger scale as may be necessary to simplify any peculiar features. The design of each building should show—(1) Ground-plan of each floor. (2) Front elevation of each building. (3) Such sections, transverse and longitudinal, as may be necessary to illustrate all of the above. The plans must be accompanied with specifications of the details of work, materials, and cost, that will enable those having the matter in hand to understand what is meant by the drawings. The designs are to be sent to James Whitworth, President of the Board of Commissioners of the Watkins Institute, before the first day of September, 1881. They will be at the risk of owners while in transit and in the board's custody. Those designs to which the commissioners may award prizes will be retained, but all others, subject to the casualty of loss or destruction, will, upon

request, be returned to the authors, provided they have been inclosed to the commissioners in a metal or strong paper envelope 4in. in diameter. The Board of Commissioners will select out of the designs sent them the three which, in their opinion, more nearly meet the requirements of these specifications, having in view especially the limited amount of funds at their disposal to accomplish the improvements, and will pay to the author of the design which may be designated by them as No. 1, 300 dols.; to the author of design No. 2, 125 dols.; and to the author of design No. 3, 75 dols. Further information may, we suppose, be obtained of Mr. James Whitworth.

PUBLIC HALLS, BELPER.—The directors have selected the design submitted by Mr. John Johnson, A.R.I.B.A., 9, Queen Victoria-street, London, E.C.

SWANSEA.—In a local report of the proceedings of the Swansea town council on the 13th inst., the Mayor is stated to have said that as to the competition plans for the new street, he had been in communication with the persons who signed their designs "Pro Bono Publico" and "Progress," and he found that whilst "Pro Bono Publico" was willing to accept half the premium (£50) offered for best sketch of buildings for the new street, the architect whose plans were known as "Progress" declined to be a party to any such division. The matter would therefore have to be reconsidered at the next meeting.

WIGAN PUBLIC BATHS.—The baths committee of the Wigan Corporation have awarded the first prize (£20) in the competition for designs for public baths to Mr. George Heaton, architect, Wigan, for his design marked "Vive le Maire." The second prize (£10) was awarded to Mr. H. J. Tait, of Bradford and Wigan, for his design "Experience B." At their meeting on Wednesday week Mr. Heaton was instructed to prepare particulars and quantities, in order that the committee may advertise for tenders. The arrangement of the building includes a first-class plunge-bath for ladies and first and second-class plunge-bath for gentlemen, slipper-baths, and the usual accommodation, including a residence for the manager. The estimated cost of the building is £5,000. A site has been secured fronting the Free Library, and forming part of the Old Grammar School Croft, in Millgate.

WINDERMERE.—We take the following from the *Bowness and Windermere Chronicle*:—"A SUCCESSFUL BOWNESS ARCHITECT.—A prize being offered for the best plan of a new Chapel of Ease for Bowness and Windermere, about fifty plans were sent in from various parts of the country, and by many well-known and eminent architects. On Saturday, the 25th ult., the committee for examining and choosing the plans met, and as is usual in such cases, the plans were examined without prejudice, the letters and names of the architects being kept back till the choice was made. A plan was fixed upon, the motto of which was 'Truth.' After passing all the usual forms of approval and election, the name of the successful architect was found to be Mr. Joseph Pattinson, the fourth son of Mr. Thomas Pattinson, of Elton-grove, Bowness-on-Windermere, now in the employ of Mr. Ferguson, of Carlisle. The announcement has been received with pleasure by all the friends of Mr. Pattinson. His début is early in his career, and bids fair for great success.—Communicated."

The new church of St. Andrew, Rowbarton, near Taunton, was consecrated on Thursday, the 14th inst., by the Bishop of Bath and Wells. The church is Early Pointed in style, and consists of nave, north and south aisles, tower at south-west corner, surmounted by spire and chancel. The external walls are of Westleigh stone, with Douling stone dressings, and the roofs are of Bridgewater tiles. The internal walls are lined with bricks, the floors are laid with Minton's tiles, and the pulpit and font are of Beer stone. Pitch-pine benches seat 500 persons. Mr. H. Spencer is the architect, and Mr. Spiller the builder; the cost has been £2,332, under 45 per sitting.

The surveying committee of the Bath city council have reported to the latter body that as they have no power to superannuate Mr. Davis, the city surveyor, it is desirable that, in consideration of his long services, Mr. Davis be appointed consulting surveyor at a salary.

INGLESIDE, PUTNEY.—COFFEE TAVERN AT SEAL, KENT.—FIRST AND THIRD PREMIATED DESIGNS FOR PROPOSED NEW CLOCK TOWER AT BRIGHTON.—DESIGN FOR HOSPITAL.—NEW HOTEL, ROYAL ALBERT DOCK.—PROPOSED NEW AISLE, CHARD CHURCH.

OUR LITHOGRAPHIC ILLUSTRATIONS.

INGLESIDE, PUTNEY (MR. W. YOUNG'S HOUSE).

In building a house for one's self at the present day, the great difficulty in the suburbs of London, is to find a good site. Mr. Young thinks he has been fortunate in securing a site which it would be difficult to surpass anywhere in the neighbourhood of London. Ingleside, named from one of the principal features of the house, the ingle nook and recessed fireplace, is situated on the west hill between Putney and Wandsworth, and about half a mile from the river. The position is high enough to command, from the ground-floor, a full view of the river from Putney to below Wandsworth, with the grounds of Hurlingham and Ranelagh on the opposite side. The object of the architect was to get something a little picture-que without being extravagant, either in idea or cost. The entrance-door is very deeply recessed, with a flat pointed arch, and has been beautifully executed in red brick. The bay window is placed at the corner of the drawing-room, and has a view both south, east, and west. This window is carried up to the second floor, and is finished with a high kind of turret roof. The roof of the house to the Oakhill-road front is hipped, with a bold dormer window running out at the upper part. This window has a deep plaster cove, with decorative ornaments scratched in the plaster, and some Venetian glass bullseyes of different colours introduced as the centres of flowers with very telling effect. The walls are of red bricks, and very bright picked stocks, and the roofs are covered with brown tiles. The hall and staircase, which we may illustrate at another time, is chiefly noticeable for a staircase out of the common, executed in pitch-pine. The little break extending into the drawing-room at the door, is treated as a porch in the room, being only carried up about 8ft. high; above this the walls of the room are square. On the hall side this feature forms a deeply-recessed arch. The principal feature in the dining-room is a deeply-recessed fireplace, with seats at the sides. A drawing of this is now in the Royal Academy Exhibition. The arch is divided into three, by two massive turned pillars, which, with the chimney-piece and the other wood-work of the room, is executed in pitch-pine. The walls of the room are decorated with a Japanese leather-paper for a dado, and above this arching with Russian oriental tapestry. The chimney-pieces throughout are of American walnut and pitch-pine, and were executed by Mr. Robertson, of Kennington-road, from the architect's designs. The stained-glass was done by Messrs. W. B. Simpson and Son and Mr. Brown, and the general contractors were Messrs. Green and King. The painted panels in the case of the dining-room fireplace are from the brush of Mr. H. W. Batley.

COFFEE TAVERN, SEAL, KENT.

This building, which has been erected and furnished at the cost of Charles G. Hule, Esq., is situated at the extreme end of the picturesque

village of Seal, and is of red bricks, with tile-hangings and roof. It contains parlour, large bar, smoking and reading-room, committee-room (capable of being thrown into the reading-room for entertainment purposes), and retiring-room from reading-room, besides kitchen, offices, manager's residence, lavatory, &c. Attached to the bar and smoking-room are wide verandahs to take tables, &c. The walls of parlour are covered with Walton's linesta to height of top of doors, and finished with dado moulding. The gas-fittings are by Messrs. Faraday, of Berners-street, W. The place has been furnished throughout in walnut and black wood, with marble tables in bar. Mr. Hope Constable, of Penhurst, was the builder, and the architect is Mr. Edwin T. Hall, A.R.I.B.A., of 57, Morgate-street, London.

FIRST PREMIATED DESIGN FOR PROPOSED CLOCK-TOWER, BRIGHTON.

The accompanying design was placed first in the recent competition. The building would occupy one of the best sites in Brighton, being at the junction of four main thoroughfares. Accommodation is provided for a public convenience below with the tower above, and forming an extraction shaft to same. The convenience is reached from the road-level by a straight flight of steps, and is lit by glazed areas surrounded by granite balustrades. The spaces left for street refuges are large and quite distinct from the entrance to convenience. The lower portion of tower is Portland stone; the dial-chamber, ironwork; the roof, light wooden construction, dressed with copper. Provision is made for an electric ball which rises on a staff 15ft. high. The staff is wood, covered with copper; and the ball is copper and gilded. When down, the ball is held in a cup-like frame of ironwork, also gilded. The extraction shafts from basement find their outlets at the grille forming base of dial-chamber. The estimated cost of design was £1,000, though £1,500 would probably be spent, as the site would warrant the extra expenditure. Messrs. Thomas Simpson and Henry Branch, of 63, High-street, Brighton, are the architects.

THIRD PREMIATED DESIGN FOR PROPOSED CLOCK-TOWER, BRIGHTON.

The conditions of the competition restricted competitors to placing the centre of the dial 25ft. from the ground, providing a dial-chamber 8ft. square, and surmounting the structure with a staff 15ft. high, on which a ball 3ft. in diameter was to fall. The general dimensions being thus virtually settled, competitors were hampered in design, and precluded from aiming at more elegant proportions. The arrangements for the clock machinery are fully provided for, and as the ground-floor chamber only requires space for the pendulum to swing, the extra space has been utilised in the basement, by the adoption of a half-vault to secure good light and ventilation to the urinal. The clock-works are also hermetically sealed from the injurious air of the urinal. It was proposed to face the structure with white Portland stone, and surmount it with a gilt metal cup into which the copper ball would fall; and it was intended to crown the staff with the figure of Mercury. The design is by Mr. James M. MacLaren, 21, King William-street, Strand, W.C.

SUGGESTED RECONSTRUCTION OF UNIVERSITY COLLEGE.

Mr. G. Francis Jones, of Cockspur-street, Trafalgar-square, prepared this design to illustrate how Professor Marshall's "Circular Ward" plan could be applied to University College, Gower-street, N.W. A description of the design appears in our article on "Hospital and Sanitary Construction at the Sanitary Exhibition," page 96, 2nd column.

NEW HOTEL AND BUFFET, ROYAL ALBERT DOCK.

This building is now in course of erection at the Gallions Station of the new Royal Albert Dock, opposite Woolwich. The materials used for facing are red brick with hand-cut mouldings for the basement and ground-floor stories and the chimneys; rough-cast of a buff tint for the first floor, and tile hangings for the overhanging upper portion. Over the large dining-room is a billiard-room, with access to a promenade formed by the balcony over the verandah of railway-platform, from which a fine view of the docks and shipping will be obtained. The front shown

in our view overlooks the river. The building is being erected from the designs and under the superintendence of Messrs. George Vigers and J. R. Wagstaffe, the architect to the London and St. Katherine Docks Company, the frieze being modelled by Mr. E. Roscoe Mullins. Messrs. Adamson and Sons, of Ealing, are the builders.

CHARD CHURCH, SOMERSET.

The accompanying illustration represents a new south aisle to be shortly erected. In making the required addition, the architect has been guided by precedents at the parish-churches of Cullompton and Ottery St. Mary, where large aisles were added in the 16th century, and the style aimed at in the present case is the latest phase of the Perpendicular. The new aisle is part of a scheme for the general restoration and enlargement of the parish-church, for which funds are now being collected. The architect is Mr. John D. Sedding.

CHIPS

The Tottenham Local Board of Health, at their last meeting, adopted a report by the General Purposes Committee recommending the adoption of a comprehensive scheme with plans and estimates prepared by the board's surveyor, Mr. de Pape, for dealing with the storm-water of the Woodlands and Harringay Park Estates of the British Land Company in the neighbourhood of the Green-lanes. The storm-water will be discharged into the Stonebridge-brook, near the South Tottenham Railway Station. The surveyor was also instructed to prepare plans and specifications for a swimming-bath.

Mr. Mark Fisher has been elected a Member of the Institute of Painters in Water Colours.

With reference to the series of memorial stained-glass windows placed in the Roman Catholic Church of the Sacred Heart, Camberwell, by Messrs. Lavers, Barraud, Westlake, and Co., and referred to a fortnight since, we are requested to state that they were designed by Mr. Philip M. Westlake.

At the Staffordshire Assizes on Saturday a man named John Smith was convicted on a charge of having attempted to murder, by poisoning with arsenic, James Jeffries, builder and contractor, Stone, Staffordshire.

During the progress of building works at Dorchester gaol last week the scaffolding broke, and Mr. Samuel King, the superintending foreman, sustained a broken arm and other injuries, two other men being also hurt. The governor of the gaol had previously sent for Mr. King, and expressed his doubts as to the safety of the scaffolding, another similar accident having only recently occurred at the gaol.

The local board of Cottingham, near Hull, have adopted plans and specifications prepared by Mr. Jacobs, their surveyor, for the drainage of New Cottingham.

The designs for the new town-hall for Eastbourne have just been completed by Mr. Schmidt, surveyor to the local board. They show a series of offices on ground-floor for surveyor, medical officer of health, collector, &c., and retiring-rooms for the magistrates and county-court judge; over these is placed the large hall, 70ft. by 40ft., &c., reached by a central staircase, over which is a tower. The estimated cost of the building is £13,000.

The Matlock Bath local board have instructed Mr. Nicholls, surveyor, of Handsworth, to negotiate with the Matlock Waterworks Company for the transfer to the board, as the urban sanitary authority, of their works, plant, and undertaking.

An appeal has been circulated by Mr. Beresford-Hope, Mr. W. C. Cocks, and Mr. Joseph Clarke, in favour of the Royal Architectural Museum, Tufton-street, Westminster, which was founded by Sir Gilbert Scott, and which requires an additional income of £200 a year to keep it afloat.

The harbour trustees of Lerwick, Shetland, on Tuesday week considered and approved plans prepared by Mr. Cay, C.E., for harbour extensions and improvements. The present pier will be extended in solid masonry 220ft. seaward, and the estimated cost of the works is £11,800.

New board-schools have just been completed at Charmouth, Dorset. Mr. Farrall was the architect, and Mr. Pryer the builder.

Considerable improvements are about to be made to the grammar-school at Hipperholme, including the demolition of the present residence for headmaster, and the erection of a boarders' house, comprising dining and boarders' halls, drawing-room, kitchen, masters' rooms, and 19 bedrooms. The style of the new building will be Jacobean, and Mr. Richard Horsfall, of Halifax, is the architect.

Building Intelligence.

BRIGHTON.—The Prince and Princess of Wales opened yesterday (Thursday) the New Hospital for Sick Children, on the Dyke-road. The building is Queen Anne in style, and is built of bright red bricks, with terra-cotta dressings. The ground-plan is L-shaped, the one wing of building containing the three wards, and the other the administrative department, entrance, and general offices. To the right of the entrance-hall are house-surgeon's sitting-room, 17ft. by 14ft., lavatory, store-room, and kitchen, 21ft. by 17ft., the latter apartment communicating by speaking-tubes with every part of the house. On the left of hall are reception and committee-rooms, a beard-room, 36ft. by 21ft., matron's-room and stores. In the centre of building is the double-flight staircase, of stone with iron balusters and mahogany handrail. Over the rooms already mentioned are the officers' bed-rooms, &c. The west wing is planned as three wards over one other, each 59ft. by 22ft., and lighted by seven large windows, and at night by two gaseliers. Each ward contains 20 beds, and an infant's swing-cot. The walls of ground and first floors are lined with Mycenaean marble of light colour and purple-veined, with dados of Belgian green marble on ground-floor, and Rouge Royal marble in first floor, the lining of second-floor being of Keene's cement. The floors are packed with layers of asphalt and cement, in which the joists are placed, and on these are floorings of deal and oak. Warming is by a hot-air stove in the centre of each ward, and ventilation by light shafts communicating with Boyle's ventilators in the roof. At the south-west corner of each ward is a bath-room, fitted with Scheele's apparatus, and at the north-west corner are the lavatory and water-closets, fitted with Bostell's Brighton valveless apparatus. These baths and w.c.'s are contained in towers which rise from the angles of the west front of hospital, and contain the water-cisterns. In the eastern wing on top is a supplementary ward for a dozen patients. Messrs. Lainson and Sen were the architects, and Messrs. Cheeseman and Co., also of Brighton, the builders; the cost has been considerably more than £11,000.

CITY AND GUILDS OF LONDON INSTITUTE.—The foundation-stone of the City and Guilds of London Institute was laid on Monday afternoon. The Institute which has the matter in hand is one founded by the Corporation and Guilds of the City of London, and the Central Institution is situated at South Kensington, in the Exhibition-road, between the Indian Museum and the Albert Hall. It will contain 9 workshops, 3 sheds, and a mathematical classroom for the mechanical department; 13 class-rooms for physics, 7 class-rooms for art; 17 laboratories and class-rooms for chemistry, and one workshop for metallurgy; a council-chamber and six other rooms for the management; two lecture-theatres and preparation-rooms, with a large number of students' rooms, and with accommodation for house-keeper, porter, engine-rooms, heating apparatus, giving a total floor-space of 57,605ft. The architect is Mr. Alfred Waterhouse, A.R.A.

HOLBY.—The small but interesting old church of Holby, near York, having undergone restoration and refitting, was reopened for public worship last week. The cost of restoration has been about £1,000. Churchwarden restorers 100 years since had taken down the upper part of the stone building, removed the lead roofs and ancient mullioned windows, and replaced the walls with brick and the windows with sashes. Several feet of stonework, and what is believed to be the base of a very ancient apse, remained untouched. The form and workmanship of these remains pointed to its very early origin, and the architect (Mr. J. R. Naylor, of Derby) taking these points as an intimation of style, has so remodelled the church that it is a credit to all connected with the restoration. Stones with ornament and mouldings as far back as the 12th century have been found embedded in the modern brick walls; these have been carefully preserved, and now form part of the jambs to the apse windows. The whole style and fashion of the present church is in accordance with these decided marks of the early origin of this foundation.

LONGTON.—The public baths erected by the Longton Corporation were opened on Wednesday week. The exterior of the building is of red brick, relieved with white stone facings. The general design is Gothic, a prominent feature in the building being an ornamented clock-tower, provision being made for three dials. The buildings are from the designs and have been under the constant supervision of Mr. A. Hardwicke, the borough surveyor. The builders have been Messrs. Inskip, of Longton; the machinery, boilers, &c., have been contracted for by Messrs. Bradford, of Manchester, and Mr. G. H. Plant, of Longton, has carried out the plumbing work; Mr. Darwin, the manager of the gasworks, having had charge of the lighting arrangements. The whole is estimated to cost £8,000.

METROPOLITAN BOARD OF WORKS.—At the weekly meeting of this board, held on Friday, Baron H. de Worms, M.P., presented a memorial from the Greenwich District Board in support of a proposal to form a tunnel beneath the Thames between Greenwich and Poplar. Having referred to the urgent necessity that existed for better means of communication between the North and South of London, east of London-bridge, it was explained that the present scheme was for a tunnel from the East India Docks-road to the Greenwich and Woolwich main road; the gradients will be one in 40; the length of tunnel beneath the river 600 yards; and the estimated cost, without the approaches, about £500,000—less than half what it would have cost a few years since, the art of tunnel-boring having greatly advanced of late. The memorial was referred to the works committee, as was another from the Lewisham District Board of Works, asking for an extension of the main sewer from Rushey-green to Southend. For the appointment of surveyor's assistant, in the superintending architect's department, the following six candidates had been selected by a committee:—W. M. Hudson, J. Briggs, A. Hemingway, C. H. Love, A. W. Page, and F. W. Pritchard, and, on being put to the vote, Mr. Hudson obtained the post. An application from Rotherhithe vestry, for sanction to borrow £2,000 for granite and York paving works, was granted.

PARKSTONE.—A new church, dedicated to St. John the Evangelist, and erected to supply the needs of Parkstone, was opened at Heatherlands, on Wednesday, or at least that portion of it, the western, which has been completed. The architects are Messrs. Horner and Adams, of Bournemouth, and the builders the Messrs. Alner, of Parkstone. The estimated cost of the completed portion is about £800, and about as much again will be required to finish the building. The portion which was opened on Wednesday will seat about 160 people. The style is plain Gothic, and the church is built of white brick, supplied by Mr. Coles, of Bournemouth, with Bath dressings. It is 40ft. long, by 28ft. wide, and has a south porch and a vestry. The pews are of modern character, and of stained pine; the flooring of the nave is of tiles from the Poole Architectural Pottery. The building has been about twelve months in course of erection.

ST. CATHERINE'S CHURCH (R.C.) WEST DRAYTON.—The Chapel of the Sacred Heart of Jesus in this church has just been completed by the erection of an altar and reredos of stone and alabaster, designed to the style of the church, that of the 14th century. The altar is of the open form, with a stone slab supported on columns in front, and a sculptured wall at the back. The reredos occupies the whole width of the chapel, returning at the sides and terminated by columns carrying angels, it reaches nearly to the roof, and is enriched by a statue of our Lord sculptured in white alabaster, and by paintings by Mr. J. Bouvier. The execution of this work was entrusted to Mr. G. F. Anstey. The side-screens to this chapel and to the Lady-chapel are of stone, forming integral portions of the structure, and have now been completed according to the design of the architect by the execution of the carving, and of sculptured panels containing the Annunciation and the Agony in the Garden. In the baptistry the two-light window has been filled with stained glass, the work of Messrs. Lavers, Barrand, and Westlake, and a stone font erected. The font is octangular in plan, seven of the sides are occupied with panels containing the emblems of the

Passion, and the sacred monogram; the 8th is designed as a niche, having in it a sculptured group of the Baptism of our Lord. The font and carving to the screens were executed by Mr. McCulloch, the whole from the designs and under the direction of the architect, Mr. S. J. Nicholl, of 1, Caversham-road.

WANTAGE.—Tuesday week, being the festival of St. Mary's Home, was chosen for opening the two new wings that have just been added to this school. Mr. Butterfield, who designed the original building, furnished the plans for the new portion, which is built in the same style (Late 14th-century work), the lower part of the outer walls being brick, and the upper part timber filled in with cement. The bricks are from the district, and the building has a string of Bath stone. The building has been erected by Mr. Norris, of Sunningdale, and the clerk of the works is Mr. C. Brown.

CHIPS.

The corner-stone of a new infirmary at the corner of Carleton and Halifax-roads, Dewsbury, was laid on Thursday week, with Masonic honours. The building will be erected of Hipperholme stone, will have a tower 90ft. in height, and will be Gothic in style. The estimated cost is £15,000.

The roof of a terrace of the guard-house at Windsor Castle is being laid with Claridge's Pyramont asphalt. The existing asphalt having failed, it is being taken off, and the concrete on which it was laid is being made good.

The vestry of the parish of Saint Mary-at-Hill have elected Mr. Alexander Peebles, F.R.I.B.A., of Salter's-hall-court, Cannon-street, to be their surveyor, in succession to the late Mr. John Collier, deceased.

Mr. Francis J. Bancroft, a junior assistant employed in the highways department of the Islington vestry, and a student of the Highbury Institute of Art, has passed the examination in advanced building construction at South Kensington. We have noticed with approval Mr. Bancroft's work sent to the recent fine-art exhibitions at the Alexandra Palace and Richmond, Surrey.

At a recent special meeting of the Hornsey local board of health a discussion arose as to the manner in which Mr. Rogers, the surveyor to the board, had carried out his duties of late. It being stated on his behalf that the irregularity of his attendance was due to severe personal and domestic affliction, it was moved that Mr. Rogers be allowed three months' leave of absence, but the board decided by a majority of one that he be granted one quarter's salary and be dismissed at once. This decision was arrived at without hearing Mr. Rogers, who has recently supervised the drainage scheme carried out from Mr. Baldwin Latham's plans, and also completed a scheme of paving the district, at a cost of £14,000. At a subsequent meeting of the board the question of appointing another surveyor has been adjourned till next week.

Extensive additions are about to be made to the college at Pontypool. Mr. George Morgan, of Carmarthen, is the architect.

The capstone of the memorial to Thomas Clarkson, the slave emancipator, which has been erected in the High-street of Wisbech, was placed in position last week by Mr. Henry Pooley, the borough surveyor, and the workmen afterwards dined together in celebration of the event.

The memorial stones of new Sunday-schools in connection with the Wesleyan Church, College-park, Lewisham, were laid on Wednesday week. The buildings will be Early English in style, harmonising with the adjacent church; accommodation will be provided in the main room for about 300 scholars, in the infants' room for 100, and there will also be two class-rooms. The architect is Mr. Charles Bull, of Dashwood-house, Old Broad-street, London, and the builders were Messrs. D. and R. Kinnaird, of College-park, Lewisham; the cost will be about £900.

Amongst the exhibits at the Royal Agricultural Show, at Derby, is a new patent lock-jaw roofing tile, invented and made by Mr. Charles D. Phillips, of Emlyn works, Newport, Mon.; the tiles, which can be made in any clay, lock into one another at sides, top, and bottom, and are said to make an impervious roof at a price but slightly exceeding that of common pan-tiles.

A new school in Kirby-street, Snow's-fields, Bermondsey, was opened by the chairman of the London School Board, on Monday. It will accommodate 300 children, and has been erected from plans prepared in the school-board offices at a cost for building and site of £14,559 11s. 9d., or £13 3s. 11d. per head.

"To a practical man with a taste for mechanics, and the bumps of constructive treat fairly well developed, we can credit no higher mental treat than a couple of hours spent over the June numbers of that truly marvellous publication the *Engish Mechanic*. In a hundred and fifty odd pages that make up the bulky mass of letterpress, there is recondite information on almost every conceivable subject, ranging from how to construct a mouse-trap, to the latest method of calculating the phases of Orion."—*The Engineer*. Price Two-pence of all newsmen, or post free 23d.—31, Tavistock street, Covent garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is ONE SHILLING for TWENTY WORDS, and SIXPENCE for every eight words after. All Situation advertisements must be prepared.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in serial advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum post free to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33fr. 30c.). To India (via Brindisi), £1 10s. 10d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

Mr. CHARLES WILSON, of 13 and 15, Laight-street, New York City, is authorized to receive American subscriptions at the rate of 6 dols. 40c. per annum.

Mr. R. M. TUTTLE, of Titusville, Penn., U.S.A., is also authorised to receive subscriptions at the same rate.

Cases for binding the half-yearly volumes, 2s. each.

NOTICE.

Now Ready.

Vol. XL., Price 12s. A few bound volumes of Vol. XXXIX. may still be had, price Twelve Shillings; all the other volumes are out of print. Most of the back numbers of former volumes are, however, to be had. Subscribers requiring any back numbers to complete vol. just ended should order at once, as many of them soon run out of print.

ERRATA.

In first col., p. 64, last week, line 34, dele "if," and after "had" insert "letter have." BRISTOL-BUILDER P. TRAP.—In Mr. Davies' letter last week, for "Southbury" read "Lothbury" old church.

Correspondence.

SANITARY PLUMBING, AND PLUMBERS' WORK.

To the Editor of the BUILDING NEWS.

SIR,—Once more I have to address you on account of Mr. Hellyer's lectures; this time, in reference to that of the 13th inst.

At this particular lecture Mr. Hellyer seems to have somehow begun to think my criticism too pungent. When a man sets himself forward as a public lecturer, especially on a subject affecting the health of the whole nation, he must fully expect to lay himself open to criticism, and if he is incessantly making blunders that every practical man should see, he must not allow his temper to get the better of him. To wit: Mr. Hellyer descended to insolence when he publicly announced that I was "not worth smoke," and that he should not answer my letters in the BUILDING NEWS. Why? Because he cannot. Ergo, he does not.

At this lecture Mr. Hellyer provided a very extensive diagram to illustrate to his audience that Bramah used to his closet an ∞ -trap, but this was only as a waste-pipe. I presume, in his strong advocacy of the ∞ -trap, that it did not answer his purpose at the same time to let his listeners know, by showing them a full diagram, that underneath the closet Bramah had a \odot -trap to protect the inefficient ∞ -trap, which, whenever placed in the position shown in his diagram, is constantly a nuisance, and getting stopped up. In your issue of the 15th inst., you report that I said that "in Bramah's closets a \odot -trap was always fixed underneath," instead of which it should have been that "Bramah's own people always fixed the \odot -trap underneath which protected the ∞ ."

Another of Mr. Hellyer's exaggerations is in his comparison of the relative sizes of the pan-closet, and that of the valve-box of the valve-closet. What sort of a valve-box would it be that was only 9in. or 10in. super. wide?

Now, in reference to ventilation, Mr. Hellyer says that "till within these last few years the sizes of ventilating or air shafts were 1½in. to 1½in. on 4in., 6in., and 6in. pipes." This is wrong, for there are plenty of closets now in London which have been fixed at least 50 years, having the same sized air-pipe as soil-pipe carried to the top of the house; if a public lecturer falls into such errors as this, he must fully expect to be corrected.

Mr. Hellyer may perhaps think that I am somewhat severe in my criticisms; but I could not help pitying him at this lecture, when he could not get his glass ventilating model to act properly. One gentleman suggested that perhaps it was "bad ventilation in the room." Did he mean in the pipes? If Mr. H. had taken his ∞ -trap (which was filled with cold water) away, he would have found a wonderful difference in the working of the apparatus.

"H. B." writes in your last issue that I have adopted a new theory in saying that the ∞ -trap has a better chance of clearing itself than the \odot -trap, of all foreign matters, such as gravel, &c. Let me tell that gentleman that 12 years ago I explained in a public room that such was the case, for the reason that the gravel, &c., being heavy, and consequently settling to the bottom, it caught the full impetus of the current of water; whereas the floating matter being at the smaller or inner side of the circle, did not meet with the same force, so was consequently often left unmoved. Any man who understands hydraulics can comprehend this. I still adhere to my opinion that the \odot is far superior to the ∞ -trap, and as he challenges me, I am prepared at any time to prove it, and, in fact, I prefer it to the V or Mansergh trap. "H. B." also thinks I am unfair to Mr. Hellyer; but when a man professes to instruct members of any trade, and in doing so makes palpable mistakes, it is at least someone's duty to try his brother-tradesmen to put him right.—I am, &c.,

P. J. DAVIES, Hon. Mem. A.S.P.

SIR,—In your notice of my last lecture I am made to say that I would not write to your paper. This remark conveys quite a wrong impression. I certainly mentioned the BUILDING NEWS, but not with the slightest disrespect, for it is a paper I always have on my table, and have recommended to many of my friends. My simple meaning in the remark referred to being that I did not intend to write to any paper until the lectures were over; but there is now to be a discussion, and no letter may be needed.—I am, &c.,

S. STEVENS HELLYER.

21, Newcastle-street, 19th July.

BUILDING-STONES.

SIR,—Had the "Bristol Builder" who writes in your last issue given a moment's reflection, he might have seen that the buildings he names are outside the argument, they being all of recent date; for although the fact of a stone decaying within twenty years is conclusive as to its worthlessness, yet its standing well that length of time can be but negative proof of its goodness, as it ought to last two hundred years without much sign of deterioration.

His reference to a townsman linking his engagements is, unfortunately, not a singular matter in the building trade. "Bristol Builder" is doubtless familiar with the fact. For unscrupulous unscrupulousness the building trade is notorious. To shift, to shirk, to cheat,

is too much the rule. I, in common with the generality of architects, I believe, are in the practice of specifying Box-ground stone, leaving it to the clerk of works to see that such is provided; but that the cupidity of contractors, and the ignorance or carelessness of the clerk of works, renders the intention abortive I have long been aware, but failed to see a remedy for it. For the future, however, if I specify Box-ground, I will see that I get it. I shall require the builder to procure the stone from Messrs. Pictor, or some other well-known merchant, and to produce the invoice of same, and I also shall communicate with the stone-merchant on the subject. Owing to Box-ground being a little more expensive to work than inferior sorts of Bath stone, builders will, if possible, avoid its use, and, moreover, the truth about Box-stone is this, as a stone merchant put it to me, "there is good Box-ground, and there is bad Box-ground." It is therefore clear, I think, that in all buildings of importance the architect should confer with the stone-merchant, else there can be no assurance whatever that a good stone is used. The Bath-stone merchant is the only person who thoroughly understands the qualities of this very variable stone, and the onus should rest with him.

Reference has been made to the good condition of the Grosvenor Hotel. The stone certainly there stands well—in fact, the example stands alone; whilst common Bath won't last five years, here is an instance at the quite antique period of fifteen years, and not crumbling! Certainly the Brobdingnagian character of the details is in no small degree the cause of this. The projection of the main cornice and of the balcony are, too, very protective. It is certainly a good example for London, as I hold that the atmospheric influences here are much more deleterious than elsewhere. What I should like to know is this: Is it ascertained what quarry the stone came from, and could more of the same be procured, with certainty as to like durability? As to the example at Kensington, which is not good, as my description was not a mere pictorial one or based on mere assumption, and as I have no disposition to truck it, I am quite willing to take any of my Bath correspondents to the place. There is sufficient reason for not being more explicit. I have been told by one I have taken, that the major part of the decayed stones is "Stoke-ground."

I have previously had the statement of two witnesses that the stone was all Box-ground.

It is queer about this example that it was specified to be Tisbury.—I am, &c.

PHILIP E. MASEY.

SIR,—The letter of a "Bristol Builder" in your last issue calls for some explanation from us as the contractors for the restoration of St. George's Church, Gloucestershire.

The writer says the architect "did not get what he specified," and thus by implication he charges us with dishonesty, and the architect with having been deceived.

We take this opportunity to inform "Bristol Builder" that the change from "Box-ground" stone to that used, was made on our own recommendation, with the full concurrence of the architect, believing as we do that it is in all respects equal to, and in many superior to, Box-ground.

Of the merits of the latter stone we are not ignorant; but we are sure "Bristol Builder" will agree with us, that if as good a weather-stone can be found, free from the objections that Box-ground has, it would be to the advantage of all concerned to recommend and adopt it.

Our experience of the stone we used at St. George's is that it is superior to Box-ground, and hence we advised its use. Our object, however, in writing you is not to discuss the relative merits of particular building-stones, but to clear ourselves from what we feel to be an unfounded imputation, and one, we think, a "Bristol Builder" would not willingly bring against us.

We would have informed him of the facts privately, but could not do this to an anonymous correspondent.—We are, &c.

WILLIAM COWLIN AND SON.

3, Brunswick-square, Bristol, July 20.

P.S.—What does "B. B." mean by a "loony" on the face of a stone? Surely a lining is the outer covering of anything, and not the

callousness to which all exposed Bath stones are more or less liable?

FRESH-AIR VENTILATION.

SIR,—In looking through the notes on sanitary matters in your last week's paper, I notice that your correspondent condemns all manner of ventilation to soil-pipe traps, &c., except that of small pipes carried from the traps to top of roof. Now I must say that he cannot have given the matter a fair trial. Some time ago there were many letters in your paper from eminent men, giving valuable instruction, and advocating the use of fresh-air inlets, full-bore vents, cowls, &c. Having a great deal to do with ventilation at that time, I gave the matter serious attention, and can add my testimony to that of others in saying that the fresh-air method of ventilation is far in advance of any other. Below I give form of specification I adopt, and would further add that I never allow a U-trap, or any metal apparatus with container, to be used on a job, always selecting an earthenware w.c. cast in one piece and containing its own trap.

"SPECIFICATION OF W.C. FOR HOUSE.

"The sewers are to be connected with soil-pipe from w.c. through one of Stiff's (Lambeth) 'Intercepted traps,' the vent-hole next soil-pipe is to be left open, as well as the central vent, but the vent to sewer is to be sealed up. The trap is to be built in a chamber, to which fresh-air is admitted by means of a 4in. socket-drain laid on to same from some convenient position below level of trap, such as through the area walls. The w.c. is to be one of 'Bostel's Brighton Excelsior w.c.'s,' connected with the iron soil-pipe by means of a 4in. lead arm of 8lb. lead, the joints of which must be of red-lead and tow. A 4in. circular iron soil-pipe connected with Stiff's trap as shown, is to be fixed 2in. clear of the walls carried up above the roof and finished at the top with one of Howorth's 4in. Archimedean screw cowls (price 26s.), and the lead soil-pipe from w.c. (which is to be as straight as possible) connected with it by means an iron arm cast on the pipe. The water is to be laid on to w.c. through a 1½in. pipe, &c."—I am, &c.,

WILLIAM H. WILLETT.

Architectural Training School, Hereford, July 19th, 1881.

P.S.—I have caused between 30 and 40 such shafts to be erected within the last three years, and the owners would be only too pleased to recommend them.

WINDERMERE CHURCH COMPETITION.

SIR,—There is a paragraph under the above heading, in your issue of the 5th inst., that is incorrect in several particulars, and I ask your permission to amend them. It is first of all stated that the successful competitor is now a pupil in the office of a firm of architects at Carlisle.

Mr. Pattinson (the successful competitor) is an assistant clerk to a firm at Carlisle, but is about to leave their employ. It is also stated that the design by Mr. Bray, of Kendal, was placed second, and that by Messrs. Holton and Connon, of Leeds, third. This is wholly untrue, as there was no such classification. The committee, after carefully examining the fifty-two designs sent in, reduced the number to six, and from these selected Mr. Pattinson's without placing the others.

I hardly deem it worth while to notice the unworthy insinuation of the last paragraph, which hints that there was favouritism displayed by the committee. Still, in the interest of truth and fair dealing, let me simply say that there is not a word of truth in it. I fearlessly assert that till the envelope was opened bearing the motto of the successful design, not one member of the committee knew who was the author. I may state that two of my own near friends were unsuccessful competitors.

Trusting to your sense of justice to give insertion to this plain statement of facts,—I am, &c.,

EDWARD P. STOCK

(Chairman of the Committee).

Windermere, July 20.

BAGSHOT CHURCH COMPETITION.

SIR,—In November last the committee of the above advertised for designs, a short time only being allowed architects to prepare their drawings. Notwithstanding, however, the anxiety displayed by the committee to get possession of

the designs, seven months elapsed before the unsuccessful competitors had them returned. This competition is only another example of how architects are treated as *docile creatures* to be made use of. On the 20th December last we received the following post-card:—

RE BAGSHOT CHURCH.

The Honorary Secretary, Church Bidding Committee, begs to acknowledge receipt of Messrs. ———'s drawings. The Committee will not meet till after Christmas, but the competition is closed.

Bagshot, Dec. 20, 1880.

After waiting three months we deemed it desirable to remind this lethargic committee of our existence, to which we received the following:—

RE PROPOSED CHURCH.

Bagshot, Surrey, March 13, 1881.

DEAR SIRS,—There has been unexpected delay in settling about this matter, partly through the absence of the President of the Committee, H.R.H. the Duke of Connaught, for a considerable time, but I expect a final meeting will be now held and a decision come to, the result of which I will communicate to you.—Yours truly, (Signed) W. THOS. RAYNE, Acting Hon. Sec.

The onus of delay is here thrown upon the Royal President, who was probably not aware that many architects were upon tenterhooks, anxiously awaiting his return and decision. On receipt of the above communication we cheerfully settled down for another three months, when we again ventured to apply the proverbial "long pole," and remind the committee of their duty to the competitors, when we were favoured with the following (the italics are our own):—

PROPOSED NEW CHURCH.

Bagshot, June 21, 1881.

SIRS,—I will, if you wish it, return your plans at once. A decision will be come to by the Committee as soon as the result of the grand bazaar just held under the patronage of the Royal Family is known.—Yours truly, (Signed) W. THOS. RAYNE, Hon. Sec.

This letter can hardly be termed respectful to those who have given their time and experience with so little prospect of adequate return, whilst at the same time it shows that an act of injustice (to say the least of it) has been committed towards those competitors who carefully adhered to the conditions of the competition, which stipulated £3,000 as the utmost cost of the building, and on the faith of this representation, competitors (ourselves included) based their designs. As will be seen from the letter, the committee, in selecting the design, entirely ignored their own instructions as to cost, &c., by setting up another standard—to wit, the proceeds of "the Grand Bazaar, held under the patronage of the Royal Family." We are not aware what the financial results of this bazaar is; but it is extremely unfair that a design should have been selected which can be built with the nett result, whether of greater or lesser amount than the stipulated £3,000, which clearly appears to have been the case. The last straw was yet to be applied to the camel's back, for our drawings were returned (which, in fairness to the committee we must state, were carriage-paid), prior to which we received the following letter:—

PROPOSED NEW CHURCH.

Bagshot, July 12, 1881.

DEAR SIRS,—In returning your drawings, the Church Committee desire me to thank you for having furnished them, and to express regret at the delay that has unavoidably occurred in making a selection.—Yours faithfully, (Signed) W. THOS. RAYNE, Acting Hon. Sec.

The above is only on a par with the other eccentricities indulged in by this committee. Perhaps some of your readers can inform us who is the unfortunate man?—We are, &c.,

COMPETITORS.

ABBOT'S HOSPITAL, GUILDFORD.

SIR,—Your correspondent, James W. Stevens, in taking exception to Mr. Hardy's title, has himself been betrayed into an orthographical *lapsus*. As an old schoolfellow, may I ask him from whence he gains authority for doubling the final consonant?

Alike on his sonorous-worded monument in Holy Trinity Church, Guildford, and in his will, we find the Archbishop's name spelt *Abbot*, which also similarly occurs throughout the life taken from the "Biographia Britica," as well as in the memoirs of his worthy brothers.

In one case only, and that evidently by an error in transcription, can I find any evidence of the dual t, this isolated instance occurring in the Latin Charter of the Hospital, where the founder's brother, Richard, is referred to. By the bye, the said Charter contains some very quaintly-turned phrases, as to repairs, &c., which might well have been introduced in your descriptive sketch.—I am, &c.,

E. L. L.

Guildford, July 13.

Entercommunication.

QUESTIONS.

[6575].—**Parian Cement.**—I shall be glad if some gentleman well acquainted with the nature of Parian cement would give me his practical opinion upon the following:—The internal walls of a sick-ward are covered with polished parian, salmon tints, in the composition, and having been done for a number of years, the tint is fading, giving the walls and ceiling, which was white, a very patchy and unsightly appearance. Is it possible to restore the tint upon the surface? If not, what is the next best thing to do with it, and how to treat the ceiling? Whatever is applied must be a disinfectant, cheerful in tint, and reflect light. Would paint do, and what kind? It should be finished in a superior manner, if painted, with a polish, not a fatty gloss.—OLD SENSACREAR.

[6576].—**R. A.**—Would some reader kindly inform me how the degree of R. A. is obtained? I am an architectural student in Scotland. That being the case, would I require to come to London to pass an exam. or what? Please give full particulars.—JACOBUS.

[6577].—**Graphic Statics.**—I should be greatly obliged to any reader who would tell me what is the best work on graphic statics peculiarly useful to an architect, and the name of the publisher? I should like an answer from an experienced man.—E. D.

[6578].—**Sun-Sheds.**—I shall feel exceedingly obliged if any reader can refer me to any work or numbers of your journal where I shall find designs of sun sheds or arbours suited for asylum airing grounds. The designs should be simple but artistic, cheap and durable—a combination more easily desired than obtained.—A. SAUNDERS, Medical Supt., Devon County Asylum, Exminster.

REPLIES.

[6545].—**Ruins.**—Although several of our English cathedrals require the hand of the restorer, there are none literally in ruins. The ruined abbey churches are—Alnwick, Bayham, Bylands, Bolton, Croxland, Easby, Fountains, Furness, Glastonbury, Hales, Kirkstall, Netley, Rivaux, St. Augustine's Gateway, St. Mary's (York), Tintern, Wenlock, Whitby.—FRED J. FREEMAN.

[6552].—**Thickness of Piers of Arches.**—I am much obliged to Hugh McLachlan for his answer to my query. I do not know integral calculus, so must use one of the more simple methods given for finding the thickness of piers. Gwilt's formula, as I understand it, seems wrong altogether, for, as shown below, an arch with the piers 20ft. high appears to require thinner piers than one with the piers 10ft. high. It seems to me that, whether the arch is loaded or not, if the piers are increased in height, they ought also to be in thickness. Given a segmental-pointed arch with a span (=*chord*) of 24ft. —rise (=*versed sine*) of 8'4"—the centres being 8'5 below the springing line, and 3'00 on each side from centre line of arch—the radius 17'5—the thickness of arch 2'0—height of pier 10'0. Gwilt's formula is

$$x = \sqrt{2p + \frac{2pd + 2ne - 2me + \frac{b^2}{a^2} + \frac{b}{a}}{a}}$$

The values of these are

$$x = \sqrt{23'288 + \frac{146'402 + 22'232 - 22'607}{10,000} + 2'465} = 1'551 = 5'0\ 8$$

Now, taking a similar arch, but the pier 20'000 instead of 10'000, we have

$$x = \sqrt{26'288 + \frac{146'402 + 22'232 - 22'607}{20,000} + '601} = 7'755 = 4'071$$

The above values were all carefully worked out by calculation, not geometrically, and it was my endeavour to find them from the fewest possible given dimensions, viz., the span, thickness of arch, height of piers, radius, and position of centres with regard to the springing line. All other dimensions required by the formula were calculated.—J. H. M.

[6554].—**Decoration.**—I should suggest a dark brown colour as being the most suitable for your dado.—FRED J. FREEMAN.

[6555].—**Staircasing.**—In answer to "Shrewsbury," get Nicholson's or Riddell's works on "Staircasing."—FRED J. FREEMAN.

[6551].—**Well Puddling.**—Twelve inches thick of good yellow clay, well puddled, is quite sufficient, but care should be taken to have it well rammed. Another ring of 4in. brick in cement will be enough, but I should prefer 6in. thick of cement concrete composed of 1 part Portland cement to 5 parts broken stone slag or brick to pass a ¼in. ring, and 3 parts sand. Puddling should commence at level of stiff clay.—WILLIAM P. RYAN, C.E.

[6562].—**Defective Rain Water Tank.**—The whole of the old cement should be hacked off, and joints of brickwork raked out. The walls should then be rendered and floated with ½ Portland cement, ½ sand, ¼in. thick; cement should be pure. I have never known this to fail. I have constructed several rain water underground tanks, some as large as 15,000 gallons capacity, and have several others in my charge, and in no case has Portland cement failed, if plastering is properly done.—WILLIAM P. RYAN, C.E.

[6566].—**Excavation.**—The measurement of wells is usually taken as they are excavated, the diameter being the leading dimension. To ascertain the cubical contents, multiply half the circumference by half the diameter, and multiply the product by the depth.—G. H. G.

[6559].—**Assize Courts.**—A paper was read at the Royal Institute of British Architects on "Winchester Assize Courts" by Mr. T. H. Wyatt, the architect of the new part of the building, the cost of the new portion being about £22,000, and according to the published paper about 11d. per cubic foot. It was reported in the BUILDING NEWS, April 24, 1874, but according to this the cost

LEGAL INTELLIGENCE.

IN RE BRAID AND GWYNN.—In the Court of Bankruptcy, before Mr. Registrar Pepys, the debtors, who have presented a petition for liquidation, are builders carrying on business in Manor-street, Chelsea, and Vauxhall, under the name of Braid and Co. They estimate their debts at £43,000, of which £22,000 is secured, with assets, £51,000, consisting of stock-in-trade, building materials, plant, freehold and leasehold property, and book debts. Mr. J. Nicholls, on behalf of the debtors, and with the concurrence of creditors for £13,000, applied for the appointment of Mr. G. Baynam, accountant, as receiver and manager of the business, and for an injunction to restrain several actions. It appeared that the debtors had 300 persons in their employment, and their wages, amounting to £600 weekly, would have to be paid. There were also contracts in hand which required completion, otherwise a loss would ensue to the estate. His honour granted the application.

IN RE EDMUND.—This was a sitting for public examination in the Court of Bankruptcy, before Mr. Registrar Brongham. The bankrupt, who carried on business as a builder and contractor, in Colvestone-crescent, Ridley-road, Dalston, recently absconded, and was last heard of in South Africa. Upon the application of Mr. H. Reed for the trustee, His Honour ordered the usual memorandum of non-appearance to be entered upon the proceedings.

BROTHERLY AGREEMENT AND DISAGREEMENT.—At Brighton County-court an action was heard last week, in which Alfred Parsons, a builder, of Western-road, Hove, sued his brother, Albert Parsons, also a builder, of Conway-street, West Brighton, for £44 18s. 6d. as moneys due under building and plastering contracts. There was a counter-claim for £50, for rent; but for plaintiff it was contended that he only lived in one of Albert's houses as a warming-pan till a paying tenant should be secured. The counter-claim was dismissed, and a verdict given for plaintiff for £18.

CHIPS.

The erection of a new gas-holder for the corporation of Halifax has just been commenced at Stoney Roid. The contract has been taken by Mr. J. S. McKnight, and will occupy about a year in execution.

A new church, dedicated to St. John the Evangelist, is in course of erection on the hillside in Auckland-road, Upper Norwood. The architect is Mr. J. L. Pearson, R.A., and the contract for the first section of the work has been taken by Mr. John Shillitoe, of Birmingham, at £10,500, and is now in active progress, the arcade piers of nave having been set and the outer walls being raised at present nearly to the level of window-sills.

The Old Swan Inn at Fenny Stratford, which is stated to have exhibited the same sign ever since the year 1474, is now being pulled down, it having been decided by a limited liability company to erect on the site a town hall, from the designs of Mr. Gotto, of Leighton Buzzard. At a recent meeting of the directors of the new undertaking eight tenders, ranging from £947 10s. to £1,070, were opened for the execution of the scheme, and the lowest, that of Mr. Staniford, of the same town, was accepted.

St. Peter's Church, Cockett, near Swansea, a building erected in 1856, is now in course of enlargement by the addition of an aisle seating 250 persons. The architect is Mr. J. B. Fowler, of Brecon, and the cost about £1,000.

A new chapel is about to be built in the Commercial-road and Norway-place, Limehouse, E., from the designs of Mr. H. J. Hansom.

A museum of arms, which has been for some time in course of formation at Liège, is to be formally opened by the King and Queen of the Belgians on Tuesday next.

A fine-art loan exhibition is to be held at Canterbury, under the patronage of the Duke and Duchess of Edinburgh.

The fourth annual excursion of the Croydon and District Master Builders' Association will take place on Tuesday next, the 26th inst., when the members will proceed by boat from London-bridge to Richmond, dining together at the Star and Garter hotel.

The 13th-century parish-church of Holton St. Mary, near Mayland, Suffolk, is being restored at a cost of about £300. A clean sweep is being made of the old high pews, which are to be replaced by benches; the west gallery is also to be removed, the pulpit and Communion-rail replaced by new ones, the chancel-floor to be raised 6in., and the Communion-table raised another 4in. The stonework is to be restored, and both nave and chancel re-roofed. Mr. Hawkins, of Monks Eleigh, prepared the plans and is carrying out the work.

Our Office Table.

THE establishment of the Technological Examinations rendered manifest another want besides that of instructors, and that is the want of books in which a workman belonging to any particular trade could obtain the information he required about the theory of that trade. A new series of such text-books is now in preparation. It is intended eventually to include all the industries specified in the programme of the City Institute; but at first those branches of manufacture have been selected for treatment in which it appears that text-books are most required. The books will be prepared by writers familiar not only with the scientific principles involved in each trade, but with the practical details. They will be addressed to workmen and apprentices, who may be supposed to have some knowledge of the practical, if not of the theoretical, portions of their business. At the same time—since the books are intended for learners—the possession of such knowledge will not be assumed, but it will be for the most part taken for granted that the student will have in his workshop the opportunity of studying the various processes of which he reads, so that practice and theory may go hand in hand. The series will be edited by Mr. H. Trueman Wood, the Secretary of the Society of Arts, who prepared for the City Institute the revised scheme of Examinations.

PRINCESS BEATRICE opened an Art Loan Exhibition at the Albert Institute, Windsor, on Monday. The exhibition embraces works by Rubens, Michael Angelo, Titian, Canaletto, Otto Weber, Gainsborough, Bristow, E. M. Ward, J. Ward, Gustave Doré, Van de Velde, Walter Field, Greuze, E. W. Cook, R.A., D. MacIise, R.A., Van Beest, Sir Joshua Reynolds, Romney, H. Vernet, Constable, H. A. Bone, Sidney Cooper, Cattermole. The principal contributors are Sir R. B. Harvey, M.P. (Canaletto), Mr. S. Romaine, Mr. F. S. Barry, St. Leonard's Hill; Mr. J. Bowring, Mrs. E. M. Ward (including "Anne Boleyn at the Queen's Stairs, Tower," by the late E. M. Ward), Mr. V. W. Bates, Baron Schroder, Lord Ronald Gower, Mr. R. R. Holmes, Sir G. Elvey, Mr. F. Charlsey, &c. Her Majesty contributes a series of water-colours by Paul Sandby, chiefly of views of Windsor Castle and precincts, date 1750 to 1780, and several works by the same artist are contributed by other residents in the town. Mr. H. Henry sends several large panels of tapestry, some of which were recently exhibited at the Bassano Gallery. In the various rooms there are numerous other artistic exhibits.

THE Bedford Park (Limited) is formed for the purpose of purchasing the Bedford Park Estate at Chiswick. The estate was founded by Mr. J. T. Carr, with the view of securing in a London suburb houses of moderate rental, constructed on sound sanitary principles, and of a distinct architectural and decorative character. "That these features of the enterprise have been appreciated by the public is sufficiently attested by the development of the property during the period of its existence. Upwards of 350 houses have already been erected, and so great is the demand from intending tenants, that the work of building is now being pushed forward at the rate of 150 houses a year." The sum to be paid for the property is £265,850, but the owner agrees that £200,000 shall remain on mortgage for six years, at 4½ per cent. interest, and the balance will be received in cash or fully-paid shares. The capital is £125,000 in £10 shares, entitled to 5 per cent. dividend, and £100,000 in reversionary shares of £4 each to be issued as fully paid; these shares are entitled to the whole of the profits after the redemption of the ordinary shares. The vendor will make over to each subscriber for the ordinary shares one reversionary share in respect of each ordinary share allotted.

On Tuesday the annual outing of the Bristol Master Builders' Association took place, the members visiting Badminton House, the seat of the Duke of Beaufort, arriving there about one. Luncheon having been partaken of, the party were afforded an opportunity of viewing the apartments of Badminton House and the magnificent collection of family portraits possessed by the noble owner. Dinner was provided in the

evening at the Portcullis Inn, when an excellent repast was provided by the host, Mr. Davis. Mr. W. H. Cowlin (president of the association) was in the chair, and there were present Messrs. G. Wilkins, G. S. Nipper, J. Easterbrook, R. J. Crocker, J. Perkins, R. H. Carpenter (Benson and Carpenter), A. Krauss, J. Thorn, G. Humphreys, Lewis, H. A. Ferse, Chapel, J. Bastow, W. Church, S. Edwards, J. Hunter, H. Harris, Shorland, Thomas, Baneroff, G. F. Tuckey, T. Young, G. H. Perrin, Beecham, E. Jones, Marsh, J. Brown, Hannam, Wilkinson, Cloutman, W. Munroe, E. Jones (Emblin and Jones), W. Hawkin, W. Brock, E. Hatherly, A. J. Beavan, W. S. Lawrence, J. C. Wallop, R. G. Crawford, H. G. Curtis, T. Yalland, A. J. Williams, F. Ware, E. S. Wyld, A. Wilkins, Ley Dubin, and W. H. Phillips. Mr. Perrin (Taylor and Low Bros.), proposed the toast of the "Master Builders' Association," and remarked that they were all deeply interested in the toast because they were all bound up in the master builders of Bristol. He trusted that they would have better times in the future than they had experienced in the past year or more. (Hear, hear.) He had much pleasure in coupling with the toast the names of their excellent president, Mr. Cowlin, and their no less excellent vice-president, Mr. Wilkins.—The president and Vice-president having responded, the health of "The Visitors" was submitted by the Chairman, to which Mr. Beecham, Mr. S. Singer, and Mr. Wallop responded.

At a meeting of the Council of the City Church and Churchyard Protection Society held this week, Mr. E. B. Ferrey, F.R.I.B.A., in the chair, the following resolution, proposed by Mr. Henry Wright, Honorary Secretary, and seconded by Mr. H. C. Richards, barrister-at-law, was carried *nem. con.*:—"That the Council of the City Church and Churchyard Protection Society regret the recent attack upon the City Churches, and the threatened wholesale destruction of so many more, which they, on behalf of their numerous members throughout England, pledge themselves systematically to oppose by every means in their power." A large number of new members were elected, including several of the City incumbents, and most of whom have joined since the new attack upon the churches. Mr. Henry Wright stated he had communicated with several members of both Houses of Parliament respecting the Metropolitan Open Spaces Act (1871) Amendment Bill of 1881, that a clause may be inserted in committee exempting City churchyards from the Bill. Mr. H. C. Richards, barrister-at-law, has been appointed standing counsel to the society.

THE Fine Art and Industrial Exhibition at Cardiff, to be opened by the mayor of that borough on Friday next, the 29th inst., promises to be a great success. The exhibits are collected in the Drill Hall, and are divided into three sections, No. I. including paintings, drawings, engravings, photographs, tapestries and art needlework. Under section II. are classified statuary and mosaics, carved and engraved work, armour, pottery, glass, ancient documents and books, while in No. III. will be arranged wrought and cast work in metal, models, machinery in motion, specimens of manufactures and scientific apparatus. The contributions include a selection from Lord Bute's family pictures, Vicat Cole's "Noon," lent by Sir E. J. Reed, some fine tapestries from St. Fagan's Castle, pictures of local interest lent by residents of South Wales, and many works lent from their own studios by artists themselves. There will also be shown a fine collection of ivories belonging to the Right Hon. W. E. Gladstone. An industrial exhibition will be arranged in the gun-room attached to the Drill Hall, consisting of models and machinery in motion. The whole of the exhibition buildings and surroundings will be illumined by the electric light. Any profit accruing from the exhibition is to be devoted to the artistic furnishing and decoration of the Free Library, Museum and Schools for Science and Art, now being erected by the Corporation of Cardiff. A portion of that building having been specially designed for the reception of Works of Art, it is anticipated that the nucleus of a permanent Art Gallery for the Museum will be one of the results of the present exhibition, which will remain open till the end of September.

A GATHERING of scientific gentlemen and others took place on Wednesday afternoon at the works of Messrs. Clark and Standfield, the well-known engineers, of Lambeth, to witness some experiments with an apparatus termed Self-Adjusting Gripping Camel, and which has been invented by that firm with a view to recovering ships and their cargoes which have been wrecked, as well as to remove rocks and other obstructions from the mouths of harbours and rivers. The chief feature in the camel is that it takes hold of the ship completely, and restoring to it the buoyancy which it lost on submergence, brings it to the surface without any of the dangers of cutting the ship by chain attachments, which has always hitherto been the great difficulty with most other inventions for ship raising. The camel consists of a dome resting on a transverse pontoon girder, which is lowered down and lies across the vessel; attached to this are two wedge-shaped jaws which hang down on each side of the ship, and these carry on their inner faces gripping chains, curtains, and bags. These bags are capable of being inflated by air by means of tubes connected with the surface, and each portion of the apparatus can be filled with water or air at will for the purposes of inflation or submergence. The experiments were highly satisfactory, the models acting in every way to demonstrate the feasibility of this new plan for recovering some of the lost treasure seized upon by old Neptune. Miniature rocks and pieces of iron were also seized upon by the machine, and moved about from place to place.

CHIPS.

A fire broke out on Sunday on the extensive new buildings of Messrs. H. Boulton and Co., the Lambeth Potteries, it is supposed through the over-heating of a kiln, and resulted in the entire destruction of a building of four floors in height, 80ft. by 60ft. across, and in the partial destruction of the moulding premises adjoining, a building of three floors, about 200ft. by 70ft. The art department and show-rooms escaped injury.

Mr. E. J. Poynter, R.A., has resigned his office of Director for Art and Principal of the National Art Training School at South Kensington.

The Station Hotel, Inverness, is now rapidly approaching completion, and is fitted up with some very elaborate gasfittings, the gasaliers in the refreshment and coffee-rooms being especially handsome. They have been supplied by Messrs. Jones and Willis, of Birmingham and London.

Mr. Richard J. Collier, in a sale this week at Woodford Bridge, sold a plot containing about an acre and three quarters for £1,726.

The water commissioners of Stirling are about to construct, under powers given by a newly-passed private Act, an additional reservoir on the Touch Hills, from plans prepared by their engineer. The estimated cost of the undertaking is £15,000.

The Auckland burial board on Thursday night opened 42 tenders for laying out the grounds and erecting the buildings for the new cemetery, in accordance with plans prepared by Mr. J. P. Pritchett, of Darlington, whose plans were selected by competition. The consideration of the tenders was eventually adjourned till after legal sanction has been granted by the vestry.

For some time past complaints have been made about the offensive smells from the street-sewers at Portobello, near Edinburgh, and the town council adopted plans prepared by Mr. W. A. Carter, C.E., for remedying the evil. The improvements had consisted in relaying some of the sewers on the south side of the town, and in placing flushing tanks above the various conveying tanks. The alterations were formally inspected by the town authority the other day, and pronounced to be an efficient remedy.

The parish-church of Torpenbow is about to be resented and otherwise restored. The architect is Mr. John A. Cory, of Carlisle.

The Liverpool board of guardians have adopted plans prepared by Mr. T. Mellard Reed, of that city, for providing additional bedroom accommodation at the Hightown industrial school, at an estimated cost of £1,000.

A vicarage is about to be built for St. Lawrence's parish, near Ramsgate. Mr. Ewan Christian, of Whitehall, S.W., is the architect, and Mr. W. H. Port, the builder.

A brass lectern has been placed in South Pether-ton Church as a memorial of the late Lieut. H. W. Toller. It was designed and executed by Messrs. Singer, of Frome.

MEETINGS FOR THE ENSUING WEEK.

SATURDAY (TO-MORROW).—Royal Architectural Museum Sketching Club. Visit to Northfleet and Swanembe. Train from Charing cross, 2.15 p.m.

THURSDAY.—National Health Society. "The Science and Art of Sanitary Plumbing." By S. Stevens Hellyer. Final Lecture (No. VI.) Society of Arts room. 7.30 p.m.

FRIDAY.—"The Science and Art of Sanitary Plumbing." By S. Stevens Hellyer. Re-delivery of Lecture VI. Society of Arts room. 7.30 p.m.

Holloway's Pills.—These famous Pills purify the blood, and act most powerfully, yet soothingly, on the liver, stomach, kidneys, and bowels, giving tone, energy, and vigour to the whole system. They are wonderfully efficacious in all ailments incidental to females, and, as a general family medicine, are unequalled.

Douling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to

CHARLES TRASK,
Norton-sub-Hamdon, Ilminster, Somerset.
—[ADVT.]

McLACHLAN & SONS, 35, St. James's street, S.W. Builders, Decorators, and House Painters. Designs and Estimates. General Repairs and Alterations Executed. Experienced Workmen always in readiness, and sent to any part of the country.—[ADVT.]

BATH STONE.

BOX GROUND,

THE BEST FOR ALL EXTERNAL USE.

CORSHAM DOWN

CANNOT BE SURPASSED IN BEAUTY OF APPEARANCE FOR INTERIOR WORK.

PICTOR & SONS, BOX, WILTS.

(See trade advt. on p. XXV.) ADVT.

TENDERS.

Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender—it adds to the value of the information.

ABERDEEN.—For repairs at Aberbrat, near Menai Bridge, for Mr. J. Richardson. Mr. R. G. Thomas, Menai Bridge, architect:—

Humphreys, W.	£300 0 0
Jones, H., Menai Bridge (accepted)	256 0 0

Messrs. Bennett Bros., Liverpool, tender accepted for grates, ranges, chimney-piece, painting, and decorating, &c.

ACTON, W.—For the erection of new folding-room at the Steyne Mills Laundry, Acton, for Messrs. Rush and Co. Mr. E. Monson, Jun., Grosvenor House, The Vale, Acton, W., architect. Quantities supplied:—

Eydman, E., Acton	£387 0 0
Maton, C., Kew	347 0 0
Dorey, J., Brentford	338 0 0
Nye, W., Ealing (accepted)	319 5 0

ACTON, W.—For the erection of house and laundry in Stratford-road, Acton, W., for Mr. T. J. Howell. Mr. E. Monson, Jun., Grosvenor House, The Vale, Acton, W., architect:—

Whiteman, T. W., Acton (accepted)	£600 0 0
-----------------------------------	----------

ROGERSWADE.—For building an engine-house in Rose-lane, for the Fire Brigade, for the vestry:—

Twelvevices (accepted)	£200 0 0
------------------------	----------

BIRMINGHAM.—For buildings, for the Mosely and Bal-sall Heath Institute, Birmingham. Mr. W. Hale, architect. Quantities supplied:—

	A.	B.	£
Taylor, S.	£4,100
Smith, T.	£2,350	£1,650	4,000
Barton, W. H.	2,297	1,636	3,933
Moffatt, J.	2,170	1,563	3,733
Matthews, W.	2,198	1,528	3,726
Burnley, J. and Sons	2,028	1,559	3,587
Brooks, W.	2,075	1,589	3,665
Smith, B. N.	2,090	1,449	3,538
Bowen, J.	1,990	1,485	3,474

A. Lecture-hall, stage, and retiring-rooms. B. Front building, class-rooms, second lecture-room, and caretaker.

BRENTFORD UNION, ISLEWORTH, W.—For the erection of new wing to infirmary, for the guardians. Mr. E. Monson, Jun., Grosvenor House, Acton, W., architect. Quantities by Mr. F. T. W. Miller, 6, Guildhall Chambers, Basinghall-street:—

Reading, C. W., Belgrave	£4,080 0 0
Shuff and Co.	4,080 0 0
Stevens and Bastow, Bristol	3,850 0 0
Nightingale, Lambeth	3,797 0 0
Vernon and Ewens, Westminster	3,790 0 0
Haynes, H., Alpertown	3,750 0 0
Taylor, T., Uxbridge	3,701 0 0
Gibson, G., Southall	3,469 0 0
Jones and Co., Gloucester	3,450 0 0
Brinsden, T., Brentford	3,425 0 0
Hiscock, T., Hounslow	3,399 0 0
Beauchamp, J., Brentford	3,375 0 0

ASSISTANT (Architect's) WANTS SITUATION in London; age 23, 13 years' experience. Details, working drawings, designs, quantities, and perspective. Salary moderate.—X., care of T. S., 10, Huntley-street, Bedford-square, London.

ASSISTANT (Architect and Surveyor's), with 6 years' experience, desires a RE-ENGAGEMENT. First-class Draughtsman; geometrical, working and detail drawings. High class perspectives in pen-and-ink. Quantities, specifications, and good land surveyor. Hard worker. Excellent references. Terms, 30s. per week.—Address, "ALPHA," 23, Ford-street, Derby.

DRAUGHTSMAN (good) WANTS OCCUPATION, at home or otherwise. Any kind of drawings, tracings, &c., neatly and expeditiously executed. Highest references.—Address, H. M. 24, Burton-crescent, W.C.

EVENING EMPLOYMENT required by a fully-qualified Assistant, to ink, finish off, or trace drawings, at home or otherwise. Terms moderate.—L. G., 2, Rosemead-road, Shepherd's Bush, London, W.

GLASGOW MUNICIPAL BUILDINGS COMPETITION.—Architect's Assistant wishes SITUATION (London preferred); nine years' experience. Proficient in classic, competitive work, and perspective. Also a curate working drawings, details, levelling, and surveying.—Address, T. ROBERTSON, Grainger-works, Ayrton-road, Pollok-shields, Glasgow.

JUNIOR ASSISTANT desires ENGAGEMENT in Architect and Surveyor's Office; 5 years' present situation.—W. COATES, 7, St. Martins, East Leicester.

THOROUGHLY Competent Architectural Assistant requires RE-ENGAGEMENT in Provincial or London Office. Good references given. Age 25.—Address, J. G., Longfield Wake, Green-road, Moseley, Birmingham.

TO ARCHITECTS.—A Young Man (just completed his articles) wishes for an ENGAGEMENT as Junior Assistant, is a good draughtsman, and has a knowledge of quantities and surveying; good references.—Apply, A. B. 2, Town Bank-terrace, Ulverston.

TO LONDON ARCHITECTS.—The Advertiser (22) desires an ENGAGEMENT in a London Office. Geometrical, working, and detail drawings. Quick draughtsman in outline, perspective, both exterior and interior, and can sketch fairly. Furniture and detail drawings of coloured decorations from rough notes.—Address, CHAS. H. SIMPSON, late pupil, and care of Mr. Chas. Noel Arnold, York Diocesan Surveyor, Architect, Whithy, to whom reference may be made.

TO ARCHITECTS.—A clever, trustworthy Assistant DISENGAGED. 12 years' experience. Good examples in colour, and with first-class references.—J. T. 23, Derby-terrace, Derby-road, Uxbridge.

ADVERTISER is desirous of an APPOINTMENT in a Builder's office with a view to partnership. Has had some experience both at bench and in office, satisfactory references required and given.—Apply by letter only, giving full particulars, to S. G., Office of the Building News, 31, Tavistock-street, Covent-garden, W.C.

BELLHANGER, Hot Water, and Gasfitter (first-class), seeks SITUATION.—J. B., 8, Woodstock-street, Oxford-street, W.

BRICKLAYER, Plasterer, Slater, &c., with Handy Lids, wants EMPLOYMENT. References.—JONES 50, Kirkwood-road, Peckham.

BRICKLAYER (good jobbing) and Plasterer.—EMPLOYMENT WANTED.—G. SMITH, 15, Bromfield-road, Union-road, Clapham, S.W.

BUILDER'S CLERK requires SITUATION. Well acquainted with bookkeeping and the general routine of a builder's office. Good draughtsman. References to London builders.—A. Z. 3, Paradise-terrace, Hickey.

CARPENTER and JOINER wants JOB; wages moderate.—WALTERS, 5, Evans Cottages, Lower Kennington-lane.

CARPENTER and JOINER wants JOB, day or piece, where he can take his boy.—W. C., 41, Hatfield-road, East Dulwich.

CARPENTER wants JOB, bench or jobbing.—Address, J. V., 103, Hanbury-street, Mile End New Town.

CARPENTER and JOINER.—Young Man wants JOB, good at bench, wages 8s.—T. C. 3, Florence-road, Grove-lane, Hackney.

CARPENTER (good jobbing) wants EMPLOYMENT, town or country; wages moderate.—Address, J. M. 33, Queen's-street, Horseferry-lane, S.E.

CARPENTERS and BUILDERS.—A Young Man requires a SITUATION as Improver or to work under another man.—H. GAUNER, 151, Monck-road, Victoria Park, E.

CLERK OF WORKS for Buildings or Gentleman's Estate. First-class reference.—X., care of Mr. G. Pike, 57, South-street, Exeter.

GASFITTER, Hot Water, and Bell-hanger.—EMPLOYMENT WANTED by a steady Young Man.—Apply to J. E. 111, St. Katherine-road, Notting-hill.

GASFITTER, Bellhanger, and Lock-smith wants EMPLOYMENT.—GASFITTER, 68, King-street, Regent-street, W.

GAS, Bells, Hot Water.—EMPLOY-MENT by thorough good General Hand.—H. H. 30, Tufston-street, Westminster.

HANDYMAN wants EMPLOYMENT who can do painting, distemper, repairing roofs, drain, bricklaying, masonry, and other building repairs; good references any part.—J. W., 12, Croydon-street, Marble-hill, W.

PAINTING, &c.—JOB WANTED by 2 good men; piecework.—K., 69, Langbourne-buildings, Finsbury.

PAINTER'S and BUILDER'S WORK WANTED by a Young Man used to painting, distemper, &c. 6d. per hour.—50, Queen-street, S.W.

PLASTERING or CONCRETE WORK WANTED. Labour only, or as Foreman. Good references as to competency.—Address, A. NORRIS, 41, College-place, Camden Town, N.

PLUMBER wants a JOB.—COTTON, 47, Pembroke-street, Caledonian-road.

PLUMBERS.—Improver, with tools or materials, in good shop, wants a JOB; 6 years' experience; wages 6d. Address, C. S., 3, Golden Lion-place, Aldersgate-street, City.

PLUMBER (experienced); fill up time painting, glazing, &c.; SITUATION WANTED.—PLUMBER, 25, Ballspond-road.

PLUMBER (good), &c., wants JOB or CONSTANCY.—Y. Z., 39, Lockley-street, Limehouse, E.

PLUMBER and 3 Branch Hand.—Young Man wants PERMANENT SITUATION (jobbing preferred).—T. M., 172, Spa-road, Hammersmith.

PLUMBING JOBS (piecework) WANTED by an experienced Workman.—G. G., 78, Broomfield-street, Waltham.

STONE-CARVER wants RE-ENGAGEMENT in a good monumental yard, with a knowledge of masonry and lettering. A constant job preferred.—Address, C. BENNETT, Lower Maudlin-street, Barnstable.

THREE-BRANCH HAND, Plumber, Painter, Glazier, wants a SITUATION. Can fill up time at all house repairs.—T. FITZGERALD, 69, Marylebone-lane, London, W.

WANTED, EMPLOYMENT in Mea-suring-up Brickwork, &c., or measuring from drawings, by a practical man. Many years Builder's Foreman. Terms (by hour) moderate.—A. JONES, 39, Woodchester-street, Harrow-road, W.

THE ARCHITECTURAL TRAIN-ING SCHOOL, ST. NICHOLAS SQUARE, HEREFORD.

Pupils, from 12 years of age and upwards, prepared for the profession in all branches. Thorough outdoor practical knowledge, &c. Terms from £70 per annum, with board.

WILLIAM H. WILLETT,
Professor of Architecture, Drawing, &c., at various Colleges, and Head Master of the Hereford Art School.

THE LONDON DRAWING OFFICE,

No. 58, London Wall, E.C. For the execution of high-class ARCHITECTURAL DRAUGHTSMANSHIP. Perspectives outlined, etched, or coloured. Designs, Detail and Working Drawings, Tracings, &c., on moderate terms. Etchings for Photo-lithography. Competition work. Manager, Mr. E. H. LLOYD. Pupils required.

PERSPECTIVES in Pen and Ink, and other Drawings made at moderate charges.—J. O. BUCKLE, architect, 10, Adam-street, Adelphi, W.C.

PERSPECTIVES and other DRAW-INGS made, coloured, etched, or finished in any style, on moderate terms, by W. PRINCE, 107, Disraeli-road, Fulney, S.W.

MANCHESTER and NEIGHBOUR-HOOD.—Drawings prepared for all kinds of work. Quantities taken off, works measured up, and accounts adjusted. Surveys and Levelling.—CHARLES P. CRAPP, Architect and Surveyor, 65, Market-street, Manchester.

COMPETITION WORK.—A HIGH-CLASS SPECIALIST, with 20 years' successful experience, offers CONFIDENTIAL ASSISTANCE. Own residence.—EXPERIENTIA, 45, Albion-grove, Barnsbury, N.

PERSPECTIVES, General and Work-ing Drawings, Details, Sketches, &c., prepared in any style, and on the lowest terms. Specimens shown, and references given. First-class work guaranteed.—T. N. L., 37, Walbrook, E.C.

TO ARCHITECTS.—TEMPORARY ASSISTANCE rendered on moderate terms. High-class Perspectives coloured or etched, finished drawings from rough sketches.—Address, A. K. A., 21, King William-street, Strand, W.C.

CRICKET.—An Eleven, the Fast and Present Assistants of an Architect and Surveyor's Office, desire to PLAY A MATCH during the season, near Town, with an Eleven from any other Office on similar terms.—Communications to J. W. STEVENS, 6, Southampton-buildings, Holborn.

CHARVED OAK PULPIT and PRAYER DESK, with all the Pews, FOR SALE, comprising several thousand feet of good deal framing, now in the Church of St. Peter, Vere-street, Oxford street, to be removed after the 25th inst.—For terms, apply to CORNISH and OAYLIT, Builders, North Walsham.

SECOND-HAND GENERAL JOINER, MORTAR MILL, and 8 H.P. PORTABLE ENGINE FOR SALE, in first-class order.—Apply, CHARLES POWELL and Co., 60, Gracechurch-street, London.

THEODOLITE WANTED, 4in. to 5in., modern manufacture, and in first-class condition.—state price, name of maker, &c. London replies only.—T., 6, Edin-burgh-terrace, Shepherd's Bush, W.

THE BUILDING NEWS.

LONDON, FRIDAY, JULY 29, 1881.

TOWERS, AND THEIR TREATMENT.

THE value of the diminution of towers has been dwelt upon by a few writers, though it is strange that architects will build them with straight parallel sides, in utter neglect of the optical principle that we see things in spherical perspective. The late Viollet le Duc speaks of the value of a gradual diminution or tapering in towers and façades, and mentions several examples where the profile has been made to conform to the law. So also Sir Edmund Beckett, in his "Book on Building," has pointed out the importance of a gradual diminution in all towers, and cites the Canterbury central tower and the Victoria tower, Westminster, as instances where no attempt has been made to follow so plain a rule, the consequence of which is that they look top-heavy. It might have been added that, but for the natural law of perspective which makes an object diminish as it recedes from the eye, the top-heaviness would be positively painful to contemplate, and the amount of diminution due to this cause may be observed in any photograph of a lofty tower taken near it. The same writer says if towers have no set-offs they should be made to taper at the rate of about 1 in 120. Several old towers confirm the value of the rule, and are made to batter upwards with the obvious advantage that they look higher, and are, in reality, more stable. When set-offs are made, the stages are best regulated in height by some gradation. The upper stage looks well if less in height than the next one, the set-offs being obtained at the levels of the window-sills, or the buttress weatherings. In the design of pinnacles a setting inwards at their base is a decided improvement, and the old builders seem to have paid more attention to these features than modern architects, at least in regard to their profile. The towers of Worcester, and especially of Gloucester Cathedral, give us some idea of the elegance to be derived from a gradation in the tower and buttresses, and the tower of Tewkesbury furnishes a better example of the same principle, one that has been accepted by no less an authority than Mr. Street, who, in his Academy Lectures, mentioned the principle of gradation, and illustrated his remarks by referring to Giotto's campanile at Florence, where the architect has observed a kind of rhythmical law in spacing the stages. On the contrary, its rigid straight angle lines, as in the central tower of Canterbury Cathedral, look stiff and metallic, and the same remark applies to many modern specimens of tower-building.

In examining more minutely some of these towers, and many of those which abound in Northamptonshire and Somersetshire, we find a considerable set-off at the principal horizontal divisions. In one or two instances, as at Kingsthorpe Church, Northamptonshire, the walls sensibly batter, but as the horizontal string-courses and stages gave so excellent an opportunity for the diminution, it is reasonable to conclude that the builders adopted in preference so easy a means of preserving a pyramidal outline. At Tewkesbury Abbey, for instance, the set-offs occur just below the parapet, and again between the plain part of tower and the lower range of Norman windows. These set-offs are simple weatherings or splays. They add much to the quiet dignity and stable effect of the central tower. It is rather curious to observe the Early Norman builders fully recognised the advantage of diminish-

ing the thickness of their walls in this manner, and no doubt it was the desire to make their towers stable which chiefly prompted them. Probably they derived their notion from the round towers of Ireland, or the brochs found in North Scotland, in both of which classes of towers a sensible tapering of the outline is met with. The round towers on the coasts of Norfolk and Suffolk may also be instanced. Considerable diminution in three set-offs occurs at St. Alban's, another Norman tower; the flat buttresses are broken into two stages at the top of about equal height, and on each of the splayed weatherings the walls are set in. Earl's Barton, Northamptonshire, well known as a type of Saxon workmanship, shows three well-marked set-offs at the string-courses, and the stages have a pleasing gradation, the upper one being much lower, and the two middle stages about equal. The well-known tower at Raunds, a fine Early English example, has a very gradual diminution, though the spire is excessively lofty for the tower.—*BUILDING NEWS*, p. 378, Vol. XI. The tower and spire at Ellington, in Huntingdonshire, show a better type.

The western towers of York indicate a pleasing gradation or diminution in the angle-buttressing, which leads the eye well up; but the central tower is less satisfactory, the buttresses being straight and unbroken. Need we mention the towers of Wells and Exeter? At Durham, the central tower has a particularly pleasing effect from a distance, owing to the diminution and the broken profile due to the angle-buttresses. Lincoln and Lichfield, both imposing examples of tower and spire growth, are no exceptions to the rule, and the Late Gothic towers of Boston, Lincolnshire, and Taunton, in Somersetshire—the former especially—owe much of their beauty to the gradation and profile. Many an unknown and comparatively neglected building or ruin affords abundant proof of the universality of a rule which has been questioned by many modern architects. Those who know Ulverscroft Priory will find a beautiful but ruined tower, of extreme delicacy in outline, and whenever an example may be found which contradicts the principle, it will be discovered that any beauty it possesses resides almost entirely in the detail.

One of the most noticeable instances of a building where the sides are built perfectly vertical occurs in the ancient west front of St. Denis Abbey, mentioned by Viollet le Duc, and the same writer alludes to a like defect in several fronts dating from the end of the 12th century, especially the church of Notre Dame at Mantua. The effect of these is to make the façade appear wider at the top. The whole question of outline is involved in the subject, and no one has spoken with more authority on this point than Le Duc himself. He, in one place, recalls the importance of attending to the design of the angles of edifices, and especially alludes to the value of preserving a clear outline by accentuating the angles by features in bold relief. The inserted angle column is one of the expedients used by architects whose materials were small, to give a sharp outline. Usually the shaft is of a single piece of stone or marble. There is a mechanical advantage gained by a stiff rigid angle to a tower: it throws the weight towards the centre and prevents settlement, though how very few of our architects ever think of this use, or introduce the angle pillar for such an intelligent purpose. It is rather used as an unmeaning ornament. The front of Notre Dame, Paris, has been mentioned as another example of the knowledge, taste, and study of its builders, and if the two towers had been completed by the spires intended, it would no doubt have been a fine façade. The angle treatment of the towers, the massive, well-graduated buttresses,

and the manner in which the open upper gallery was designed to lead the eye to the spires, are certainly noteworthy, though, unfortunately, the latter never having been completed, the façade has a heavy appearance. There is sufficient left, however, of the intention to show that the apparently unmeaning termination of the buttresses was really evidence of a desire to make an agreeable transition from the tower to the spire.

To the credit of the Renaissance architects, the great value of diminution by well-arranged set-offs was quickly appreciated, and Wren, whose towers are perhaps the best of his works, has shown his skill in many of them.

THE SMOKE-ABATEMENT EXHIBITION AT SOUTH KENSINGTON.

THE idea of holding an exhibition of apparatus and inventions connected with the prevention of smoke has been warmly taken up, and the movement already bids fair to produce important results. Very numerous applications have, we learn, been received from manufacturers and patentees for space to show their inventions, and on behalf of these who have novel plans to bring forward in competition for the valuable prizes which are to be offered, the Board of Trade have agreed to afford provisional protection for six months to all inventions duly entered in accordance with their regulations. The owners of smokeless coal, anthracite, and various kinds of patent fuel are also on the alert, and every effort will be made to bring the merits of these materials before the public. We are informed that among the applications for space, the makers of mechanical stokers, special furnace doors and furnaces, improved boiler settings and fire-bars will be well represented, and it is intended, as far as may be, to show these contrivances in actual operation, either at the Exhibition, or on boilers and furnaces which have been kindly offered for this purpose by steam-users and manufacturers in the vicinity of the Exhibition buildings at South Kensington.

The practical trial of the inventions submitted to the committee of experts will, in fact, constitute one of the special features of the exhibition, and the reports of the investigations of the judges respecting the merits of the various appliances will, it is hoped, be of great service to the public in demonstrating the value of the objects shown in the exhibition. There will doubtless be many difficulties in the way of thoroughly testing the different inventions; but arrangements will be made for comparative trials directed to ascertain their power of preventing the formation of smoke and other noxious gases; their economy as respects fuel and saving of labour in stoking, &c.; their wear-and-tear on the boilers, and the actual work done as tested by the volume of water evaporated in a given time; flue temperatures, &c. In addition to boiler-furnaces, the committee will also have to adjudicate on improved kilns and oven-furnaces; on gas-producers and apparatus for the use of liquid fuel; and on domestic grates without number. Several important inventions are spoken of as coming from America, and manufacturers from France, Belgium, and Germany will be represented.

The use of smokeless coal and anthracite is almost unknown in this country for domestic purposes, and although many manufacturers are now prepared to supply fireplaces in which such coal can be consumed, we doubt if the public will readily adopt this kind of fuel. The absence of flame and the impossibility of stirring and poking an anthracite-coal fire will be regarded by many as a great objection. There is, perhaps, scarcely any bad habit more deeply rooted

among Englishmen than that of constantly meddling with the fire and an anthracite fire thus treated speedily becomes extinguished. The so-called "base-burners," so much in use in the United States, where the heat of the glowing coal is seen through mica plates, are among the best of the contrivances in common use for burning smokeless coal, and, with this class of stove, an enormous economy in fuel is, undoubtedly, attained. A single stove placed in the hall or the centre of the house, will warm all the upper rooms, and the amount of care and attention required in keeping them alight is reduced to a minimum.

We are not likely in this generation, or for very many years to come, to relinquish our open fires; indeed, we very much doubt whether there would be any real advantage attained in doing so, for we gain in wholesome ventilation what we lose in wasted coal; but there are, undoubtedly, many ways in which our modern fireplaces can be made more efficient in consuming the gases thrown off from the coal, and in imparting warmth to the room. Indeed, we can scarcely conceive any apparatus more ill-adapted for its purpose than the cast-iron grate generally found in London dwelling-houses. It is a very low estimate to take of their disadvantage when we assume that three-fourths of the coal burned in them is totally wasted. When we apply a simple calculation to the number of fires actually alight on any winter's day in the metropolis, and assume that one-half of the coal only is squandered, the amount of loss we find to be going on is truly astounding, and we know of no field where inventive genius can be more profitably employed than in providing us with some means of remedying this vast source of wastefulness. Not only is the value of this coal entirely lost to us, but, above and beyond this, an unascertainable amount of injury is caused to the citizens of London by the foul smoke and gases spread around us in the atmosphere from, say, upwards of a million chimneys, conveying away the unconsumed fuel from our houses.

The Committee who have taken in hand the task of warring against smoke-production, both by manufacturers and private individuals, only need to point to a few days of genuine London fog to bring home to all of us the truth of these facts, and the importance of the work in which they are engaged, to every Londoner. How can we estimate the value of the lives sacrificed during such a fog to the atmosphere which chokes and stifles us? Is it possible to calculate the cost of artificial illumination in so many hundred thousands of dwellings? But though a day of dismal "black fog" brings home to us so vividly the discomforts of the production of London smoke, and reminds us so forcibly of the error of our ways, we must not forget that a pall of smoke is ever hanging over London, with its long train of evils. It blackens our public buildings, spoils our flowers and gardens, pollutes our water-supply, and brings with it a thousand petty discomforts, to many of which, from long habit, we have become so much accustomed that we barely notice them.

It is easy enough to write about the evils of London smoke, and London is not by any means the only sinner in this respect, for many, and, in fact, most of our large towns, suffer quite as much as we do from the "smoke nuisance," and there is a tract of country near Birmingham which we designate as the "Black Country," which has to endure almost perpetual darkness, from the atmosphere of coal-smoke which hides the sun.

Now we are told, and we know it to be a fact, that smoke is an altogether unnecessary annoyance; it is quite possible to burn coal without producing any smoke, and coal thus burnt will give out more heat, and serve the

purpose for which it is employed far better than fuel which disperses upwards of half its weight unburned into the atmosphere. With a perfect knowledge and appreciation of this fact, why is it that we continue to waste coal in the way we do? It is hard, indeed, to give any satisfactory answer to this. Some will tell us that it is because builders continue to put in the commonest and cheapest stores with which Sheffield and Glasgow can supply them, and because architects are utterly indifferent whether the rooms they design are properly warmed or not, and whether the houses they construct are duly ventilated. There is a good deal of truth in this, and we fear a great many architects will plead guilty to the charge of too much indifference in these matters; they will urge the absence of any real knowledge concerning the working of the inventions which are now being so diligently pushed by enterprising firms, and the impossibility of altering the grates and flues in existing houses. It is the want of this correct information which the smoke abatement exhibition is designed as far as possible to remedy, and if it in any way realises the hopes of its promoters, much real good may be effected by it. The public will, at any rate, be able to see the actual working side by side of all the best appliances for consuming and preventing smoke both for industrial and domestic purposes, and in the lectures and reports which are promised to us by those best qualified to pronounce an opinion, we may see some way out of our present difficulties.

It is now very widely known that the chief objects we must set before us is to avoid making smoke. It is far easier to prevent smoke than to consume it when once formed, and every appliance for burning fuel which leads to the production of smoke may at once be condemned as faulty in its work, and unsuited to its purpose.

It is easy to demonstrate that the problem of smoke consumption is far more simple for the manufacturer than it is in the private dwelling-house, and any ready plan of altering our modern open firegrate so as to render it a perfect smoke-preventer is manifestly out of the question. There are many ways, however, in which we can vastly improve our firestoves, and numerous inventions will be submitted to the judges which aim at the solution of this problem. Some patentees propose to add the fresh coal at the bottom or side or back of the incandescent fuel; others feed the fire by means of hoppers, in which the green coal, *i.e.*, the fresh charge of coal, is partly coked before it reaches the bars; while others, again, make the entire grate reversible, and turn the fire upside down each time fresh coal is to be added. Some would have us prevent the formation of smoke by the use of anthracite and smokeless coal. This fuel, though it has much to recommend it, will, we are afraid, beslow in commanding public favour, owing to the difficulty in lighting it and the want of flame. A whole school of smoke-doctors boldly advise us to discard coal altogether for domestic purposes, and to use gas both for our living-rooms and kitchens, and it is impossible to deny that gas has very many important advantages. There is, however, much prejudice against gas to be overcome before this mode of firing becomes widely used, and the gas companies will have to spend more money than they seem prepared to do in London in educating the public, and especially the working classes, in the convenience and economy arising from the employment of gas for cooking and warming. The proposal of Dr. Siemens to supply gas of two qualities—the one a cheap variety for heating, and the other a pure and high-standard gas for lighting, is well worthy of the most careful consideration.

Then we have another school of thinkers who propose to us to warm our houses and

public buildings entirely with steam or hot water, and, we believe, a company has actually been formed in America to warm an entire town by means of steam laid on in pipes like gas or water. This plan of warming, supplemented by some carefully devised system of ventilation, has more in its favour than the Continental stove system, which will never, we are convinced, become popular in this country. Scarcely any large house in modern Paris is without its "calorifer," an apparatus for the production of hot air; and throughout Germany the close stove is to be found nearly in every room. At the exhibition we may expect to see what can be accomplished by these appliances, and may learn what is good in them and what to avoid.

Much advantage we hope also will come from the experience manufacturers will give to the value and economy of the various gas-producers. There are few industrial purposes for which a gas which can be produced at 3d. per thousand feet will not be cheaper and more efficacious than coal, and when used in gas-engines motive power can be obtained at less cost than from steam. We have been informed that from some experiments recently carried out by Messrs. Crossley with the Otto engine, it was found that 3,000ft. of gas costing 9d. would do the work of 1,000ft. of common coal-gas at 3s., and that the consumption of 1-4lb. of anthracite coal per hour produces the work of one horse-power nominal. This is superior to the work done in the largest and best compound engines, which, as is well known, require 2lb. of coal per horse-power per hour.

Electricity as a lighting agent must ere long, to a very great extent, supersede the use of gas, and a great impetus will doubtless at the same time be given to the use of gas for many purposes to which coal is now applied. To predict that electricity will ruin the gas companies is to close our eyes to the value and advantages of gas for many industrial purposes for which at the present time it is little used, owing to the run upon it as an illuminant. When once the gas companies are deprived of this their virtual monopoly, they will soon see the urgent need of furnishing gas of a cheaper kind for heating and manufacturing purposes, which will be its chief use in the future. Respecting the urgent call that exists for such an exhibition as that proposed, there can be no two opinions, and we heartily wish the promoters may be able to realise their expectations, and effect some marked improvement in the atmosphere of London.

THE INTERNATIONAL MEDICAL AND SANITARY EXHIBITION.—II.

CONTINUING our notice, we find in the eastern quadrant, Messrs. Bellman and Ivey have a stall in which they display several specimens of their Scagliola, including column-shafts, pilasters, wall-linings, pedestals, and other decorative accessories. The specimen of shaft made by this firm for Carpenters' Hall is noteworthy for the excellent imitation and perfect polish which have been attained. Messrs. Bellman and Ivey show how well the material can be used to conceal iron cores, stanchions, and other supports. These can be inserted before erection, or the polished column can be cut and placed round the core of iron or brick. At the Art Union premises at Carpenters' Hall, and the Grand Hotel, Charing-cross, this plan of masking the supporting cores has been carried out with success. The "Eureka" Concrete Company, whose exhibits we briefly referred to in our last, have on view a speciality of some interest to those who desire to promote economy in the laying of gas and water-pipes. The inventor, Mr.

Nichols, lays the pipes in cement concrete grooves cast for the purpose, so as to obviate the inconvenience of taking up roads and pavements for laying. The "concrete gas detector" is a small chamber with a movable lid, by which means escape of gas can be instantly detected. It can be placed in the middle of the roadway over the main piping or on the pavement. A sectional drawing shows the method of laying the blocks and pipe. The model of stable gives a good idea of the cleanliness and surface-drainage insured by concrete paving. This paving can be laid from 8d. per foot, specimens of sewers 4ft. by 2ft. at 12s. 6d. per foot run, and sinks at 1s. 8d. per foot super, are exhibited also.

At Stand 362, Mr. Walker, East Dulwich, London, and Leeds, exhibits a large collection of architectural decorations, fire-proof flooring, stable, carriage, and foot-pavement, steps, sinks, stones, and sewers; the decorations are in solid red concrete, all of which are particularly good in design and rich in colour, comprising Queen Anne pilaster, large Classic cornice, window-head, window-sills, brackets, corbels, and steps, and being made of fire-proof material, is suitable either for internal or external decoration, as it would not in the least be affected in the case of fire or the most severe frost. Work of the same kind has been exposed for the past six winters, and shows no signs of deterioration, but is harder than when first fixed in its place. His granite and iron-slag concrete pavement and flooring we have only lately referred to. It is laid *in situ* on a bed of broken ballast, and becomes exceedingly hard and compact. Being laid in a soft state, it can be made to imbed iron joists and bars, and thus protect them from the action of fire; and this form of laying floors is now recognised as the strongest and most indestructible. Such concrete construction, 6in. thick, has been found to resist a breaking-weight of 15cwt. to 20cwt. to the square foot. We notice a sewer with lap joints made of concrete, with an invert in one solid piece, having a flat base. Mr. Walker's concrete railway platforms have been found to answer the highest expectations for strength.

Messrs. Faraday and Son have a display of ventilating gas pendants and fittings. The gas pendant is clear of pipes, and insures a good draught, and the risk of gas-leakage or the fall of corrosive dust are avoided. The Argand burner is non-corrosive, and has a lever check to regulate the flame, while the opal glass screen throws a soft light. We notice, also, some sconces and brackets of good workmanship.

Mr. James Howorth exhibits models and specimens of his revolving Archimedean screw ventilators, which are well known to our readers, and we here draw particular attention to a new patented screw exhaustor and blower, which has been contrived to meet the great want of ventilating the lower stories of manufactories and mills. The exhaustor is an Archimedean screw, working in a cylinder placed horizontally. It can be easily fixed to a wall on brackets, or to roof timbers, the exhaust being driven through a window or a tube, and can, in fact, be applied in any situation, either for the purpose of exhausting or blowing. For ventilation of mines the blower might be applied with advantage. Messrs. Kite and Co. show the siphon system applied to ventilate house-drains. There is an exhaust tube fitted with the ventilator, and another tube with an inlet ventilator fixed thereon. The exhaust is fixed at one end of the drain, and the inlet at the other end, the former rather the highest. When there is no current of air outside, the siphon principle comes into play; at other times the action is facilitated by the exhaust and inlet ventilators. The stable, dormer, and cowshed forms are well-contrived, and of slightly appearance.

Hayward, Tyler, and Co. show a large number of articles connected with modern sanitary engineering; but those to which they attach the greatest importance are the result of endeavours to provide substitutes for the "pan closet" which shall satisfy all sanitary requirements, and also be simple, inexpensive, and easily fixed. First comes their "Full Flush Valveless" closet, with patent flushing arrangement. The closet is of the "hopper" type, of very careful design, and exceptionally handsome appearance, but the closet is not sold without the whole flushing arrangement, the object being to insure satisfactory flushing in all cases where the "Full Flush Valveless Closet" is specified. As the price is only 50s. for the best closet, and 45s. for the plainer make, it is within the range of all purchasers, a comparison of prices showing that the ordinary pan-closet with flushing arrangements (which is not nearly so handsome in appearance) comes to nearly 60s., and the cheaper pan closets to about 45s. The patent flushing arrangement consists of a flushing cistern giving a flush of two gallons to conform with the requirements of the water companies, and a patent water-locking valve which prevents the cistern valve closing until the full flush has passed. The flush descends with excellent effect, owing to the make of the flushing rim, and the absence of any impediment between the cistern and the pan. It is almost needless to point out all the advantages secured by this arrangement, and it certainly is well worthy of notice. The closet, with its dish, &c., are made to go exactly into the place of an ordinary pan-closet without (in most cases) any alteration of the seat. The other closet that we notice is a valve-closet, which scarcely differs in appearance from the most expensive made, and in working powers seems identical; but, by careful organisation in the manufacturing departments, and saving of all superfluous expense, Hayward, Tyler, and Co. are able to sell it at prices which enable it to be used in numberless places where hitherto the "pan-closet" has been considered the only resource, on the ground of its comparative cheapness.

Messrs. Comyns, Ching, and Co. have several outlet ventilators made on the principle of T. Boyle's patent, the object of which is to allow the escape of vitiated air from rooms without the risk of back-currents. A series of light valves made of mica, very sensitive, and hung on copper hooks, compose these ventilators. Some are cased externally in the turret form, and others act simply on Arnott's principle, and are fixed in the chimney-breast. The inlet ventilator is simply a circular plate, and can be regulated at pleasure. Messrs. R. Bullivant, Tagliaferro, and Co. are the makers of an air-tight and noiseless sliding sash-window which they exhibit by a model. There are no beads to remove in taking the sashes out, and the weights are not attached to the sash in the usual way by a cord, but a guide-bar of hard wood is introduced, which works in a groove in the frame, and to this the weight is attached. The guide-bar has a spring packing to keep the sash in place, which prevents it rattling, and excludes dust and draught. We understand this sash has been used in the New Law Courts. We also find 2in. deal ovolo sashes of this construction costs 1s. 1d. per foot super. Passing the stall of Messrs. Joseph Kaye and Co., who show a new door-fastener and furniture, in which the old-fashioned plan of turning a handle is superseded by a knob, which is pushed backwards, the bolts having revolving ends—worth the attention of architects, the Spongy Iron Domestic Filter Co., and several other exhibitors, claim a word, but we select a few useful appliances shown by Messrs. Benham and Sons. We notice especially a disinfecting oven, having jacketed sides, heated by steam, which

can be used either moist or dry, and another very convenient oven for gas. The hospital cooking-stove of this firm is certainly the essence of compactness. It can boil, steam, bake, roast, and stew, and is a useful appliance for colonial use. The hospital sink, of enamelled iron, and other exhibits for heating, laundry, and ventilating purposes, are worth inspection. Wherever gas is used, Benham's ventilating globe light, or some like expedient of carrying off the vitiated air, is essential. Mr. R. Renton Gibbs has done much to simplify and economise hot-water apparatus, and other heating appliances. We may notice with commendation his very compact patent furnace, 3ft. high by 19in. diameter, which can be placed in any underground chamber or cellar below a hall. From this furnace a "flow" and "return" pipe is led into an ornamental coil-case, which forms at the same time a useful sideboard in the hall. We remark also the "Renton Gibbs" boiler for heating buildings, the peculiar feature of which is that the fire-box is contained in a tubular arrangement of water-pipes or bars, inclosed on the upper half with firebricks, and set in ordinary brickwork, the price of which is £8 per lineal foot. The "air-cleansing" apparatus is an admirable screen; the glass V-shaped troughs or prisms are fixed as in a Venetian blind, and form a succession of troughs, over which water falls from one to the other till it is drained off below. Through the horizontal slits between the water and troughs the air enters, after being cooled and cleansed of impurities by passing through the sheet of water. The water may be scented or otherwise treated. Gibbs' hot-water grate, in which a coil of pipe is fitted to a common grate, is a decided novelty. The pipes, in fact, form the bars, and can be made to heat the bedrooms above.

Messrs. Hobbs, Hart, and Co. exhibit several specimens of their well-known locks and fittings. The locks manufactured for asylums, hospitals, and prisons are the perfection of contrivance, and we may mention the specialities known as the "Protector," applicable to all locks, rendering them unpickable. The patent "Progress" safes are certainly all that can be wished for, combining security with convenience.

Messrs. J. L. Bacon and Co's. stall is a very instructive one. The coil of pipe bent cold shown under pressure of 3,400lb. per square inch and twisted into a knot at the upper end is interesting, as showing the ductility of wrought-iron pipe. Messrs. Bacon's hot-water apparatus consists of specially made wrought-iron tubes 1 5-16in. external diameter; they are connected by sockets screwed right and left hand, which are not affected by expansion. An automatic valve fixed in a cistern at the highest point keeps the pipes full of liquid at a certain pressure, which can be regulated. The boiler is, in fact, a series of tubes bent in tiers in the furnace. A drawing of the drying closet apparatus fixed at Milton Union Workhouse, shows a very effective method of drying by hot water. There is also a model to show how hot-water pipes can be placed behind gratings to form a skirting to a room. Very little room is taken up, and the projection is not more than that of an ordinary skirting. The firm shows a section of heating the new hospital at Antwerp by steam, in which a complete system of heating and ventilation is indicated. The Gothic coil-case coloured, and another case of a Renaissance design, painted white and gilded, are clean and delicate castings, suitable for interiors. We alluded last week to the exhibits of Messrs. A. Smith and Stevens. We may here mention their self-feeding grates for anthracite coal; also Messrs. Verity's combined boiler and coil ("Osborne") for heating halls, conservatories, &c., by gas, a very compact and bright-looking apparatus made in copper

and brass, polished or ornamented with repoussé panels. Messrs. Strode and Co. have an improved bath-heater, which heats a bath to 110° in half an hour. The heater is supplied with gas, and any water supply may be made available. Messrs. Fraser and Co. have a disinfecting apparatus, which is not only portable but cheap; heat is the agency employed. As a clean and sanitary flooring nothing equals parquetry, and we find Messrs. Howard and Sons are the chief exhibitors of this class of goods. Several excellent specimens may be seen in the hall, between the arcade and quadrant, the price of the simplest pattern being only 6d. a foot.

We alluded last week to some important sanitary fittings and ironmongery exhibited by Messrs. W. Tonks and Sons; among these we mentioned an admirable architrave ventilator (Currall's patent), which can be fitted to the head of any door or window, and becomes either an inlet or an outlet, according to the condition of the room. Mr. Mark Judge's modification is quite an architectural addition which the most aesthetically-minded could not find fault with. Currall's perforated plate or window inlet is another useful form of aperture for admitting air. The fresh air, as it enters, is directed upwards, and diffuses equally. The chimney-broast outlets, with funnel-shaped apertures, are neat and efficient outlets, and do not admit smoke. Few modern appliances for lighting equal the excellent "Libra Light" of Mr. Hopkinson. The oil is contained in a central vase, easily refilled, even when the lamp is burning; there is little or no attention required; the burner only has to be removed when a new wick is required, and the oil is kept up to the light by a beautiful contrivance known as Hopkinson's patent valve, which is constantly admitting as much oil as the light consumes, and no more. We recommend those interested to examine the very handsome lamps at the exhibition, where every explanation will be given by Mr. W. W. Hopkinson, the manager of the Libra Valve and Lamp Works. The Libra light is indeed an even, continuous light, perfect and artistic in form, and saving all trouble of trimming and loss of time.

Of sanitary closets and fittings, we may add to our former notice of Messrs. Doublton's exhibits, an excellent flush-out closet in connection with a vacuum waste-preventer, by which a single pull gives a full two-gallon flush of water, the force of which is greater at the end; also the aerating filter, invented by Mr. Bailey Denton, the merits of which we have before pointed out. By the aeration of the filtering materials any organic matter becomes oxidised, as a kind of intermittent filtration takes place. It is automatic in action, and is made of stoneware and carbon, and can be applied wherever cisterns exist. Messrs. Beard, Dent, and Hillyer show some capital specimens of plumbing, and a patent "vortex" closet. The cast-lead V dip-trap, the "ventilating drain connector for R. W. pipes, &c.," and the "artisan" closets are clever modifications. We notice also stoneware traps, water-waste preventers, lavatories and closets, a drain interceptor, and other arrangements for disconnecting soil-pipes from drains. Mr. Henry Owen has also a capital double-trapped closet, made of one piece of earthenware, divested of all complex levers and contrivances. It can be easily fixed by screws to the floor. The upper siphon is ventilated by a pipe carried through the wall, and the flushing-rim round the basin effectually washes the latter. The "ventilating valve-closet," having a vertically-hung valve, has some decided merits; the outlet from basin is out of sight in front, and there is a siphon forming part of valve, which forms the overflow. The tip-up lavatory, urinal, and slop-sink is an excel-

lent combination for saving room, well adapted for offices, &c.

Messrs. W. Ingham and Sons, Wortley, Leeds, are the manufacturers of an effective trap known as "Brown's patent accessible siphon trap." It is made of glazed stoneware with a loose lid forming the upper segment of the siphon, which gives easy access to the trap and outlet. A flat sole is cast, on to the trap, which affords a good bedding. There is an upright junction for ventilation. Another speciality is Adam's "automatic trough flushing closet," made of fireclay, in which a siphon discharges the contents. The glazed-brick fireplace, with played sides and back, is artistically designed; the chimney-piece is of wood, painted a dark grey green, relieved by tiles of brown and green; a double-trapped ventilating gully may also be noted for its simplicity. Especial mention must be made of Messrs. N. Braithwaite and Co.'s patent siphon for closet cisterns, the advantages of which are simplicity in the siphon arrangement which can be fitted to any cistern, and the avoidance of valves at the bottom, which are a constant source of trouble and leakage. The siphon is placed over the side of cistern, and is fitted to the service-pipe, the other end is connected to a cylinder in which a piston works. When this is raised by the lever the water is forced into the pipe over the side of cistern, thus setting the siphon in motion, and allowing the water to flow until the compartment is emptied. Nothing can be more efficient, as there is no complex machinery to get out of order, and no packing to decay.

Mr. J. Parker's "automaton dry-earth closets" and commodes are admirably adapted for cottages and country-houses. They are intended for dry earth or ashes, have pull-up handle and pail receptacle. The chair-pattern commodes are made in deal, painted or varnished, or in grained oak or mahogany, at moderate prices. Messrs. T. Smith and Co., of Old Kent-road, exhibit a large collection of sanitary stoneware drain-pipes, junctions, siphon and other traps, closet-pans, gullies, sewage-carriers, &c.; the Wortley Fire Clay Co. also show Jackson's patent water and gas-tight joint in stoneware tubes, which consists of an annular space between the spigot and collar filled with liquid cement by an aperture at the top of collar; Mr. W. Ramsay exhibits a model showing Jewell's system of drainage and ventilation, by "double siphon out-traps," in connection with soil and ventilating pipes and siphon closets; and in this category we may mention J. Woodward's excellent "wash-out" closet, lavatories, and sinks; Pearson's well-known "trapless twin basin closets," exhibited by Messrs. Capper, Son, and Co.; Hayward, Tyler, and Co's "full-flush valveless closet"; J. Bolding and Son's closet and trap (the "National"); J. Warner and Son's valve closets with improved basins; and some others, examples of all which will be found in this department of the exhibition. The traps and stoneware pipes shown by Mr. P. J. Davies merit particular attention.

The specimens of plumbing-work exhibited by various journeyman plumbers will be viewed with interest. Messrs. Smith and Barnes, plumbers, direct attention to a new system of making joints with spirit-lamp without pot, ladle, or irons. The specimen joints shown, invite inspection for their workmanlike qualities and cleanness. By the process adopted, the danger of fire in premises is avoided. We notice also some good "wiped" joints by J. W. Fuller, F. Shepherd, J. Vance, and others. Mr. Davies shows wiped solder-joints and bend, also a breeches-piece and trap, out of 6lb. lead made in three pieces in eight hours work. We also notice a knot-trap of 2in. pipe specimens, executed by Mr. E. Lyne, in Messrs. Benham and Son's employ. The

designs for sanitary plumbing for a town mansion, exhibited by Mr. Fairchild, a journeyman plumber, showing an exhaust and inlet arrangement, is an example of the extension of sanitary principles among the working craft. These exhibitions of plumbers' work are admirable illustrations of recent lectures on sanitation.

Messrs. Quirk, Burton, and Co. show specimens of their patent tin-lined lead pipe, in which a block-tin inner tubing is incased by one of lead. The two metals are said to be inseparable. As a security against the baneful effects of the action of water on lead, nothing can be better as a means of conveyance. The cost per lineal foot is about the same as lead pipe; for beer establishments the tin-lined lead pipe is no doubt a desirable substitute for lead, and ought to be used for all malt liquors.

At Stand 300 in Section XIII. the Albisima Paint Co. exhibit a selection of sanitary paints, made from zinc, which are well worth attention. These paints are non-poisonous, the colour is not affected by gas or atmospheric influences, they mix well with any colour, and work well; their use is decidedly economical, and we are disposed to accord them a very high place, on all accounts, among the most recent substitutes for white-lead that have come under our notice. Mr. R. Adams' converging and regulating spring-hinge for double action and rebate-framed doors, the door-spring and slam-check, the fanlight openers, the weather-tight sill-bars and bolts for casements are worth notice; we may also draw attention to Phillips' reversible window, made by J. Tomlinson and Sons, of Leeds, and an improved water-bar for casements shown by Smith and Turner. Benj. Turner's adjustable slam-spring and hall-door porter are probably equal to anything in the market. Notice may also be taken of Simpson's double-paned sashes (E. T. Gething), C. R. Stevens' steam and hot-air heater, W. Hellier's instantaneous water-heater, a substitute for the ordinary apparatus; G. T. Tonks' frictionless balanced supply valve, and the furniture shown by Messrs. Steel and Garland.

Last week we spoke of the principal drawings exhibited in the west gallery, but our notices were necessarily brief. It must have been rather a curious idea of classification which prompted the exhibition committee to place the architectural drawings and the surgical instruments together. The bills on the staircase directing visitors with the words "To the surgical instruments and architectural drawings," at least suggest a want of affinity, though the architecture, such as it is, is chiefly in relation to buildings dedicated to Esculapius. We mentioned last week a drawing for a proposed hydropathic establishment at Bournemouth. The plan of this building, we may now add, comprises a central hall, square, or nearly so, surrounded by corridors, and lighted from the top. Round the hall are arranged the drawing and dining-rooms, bedrooms and dressing-rooms, the bath-rooms being placed on one side. The author, Mr. H. H. Bridgman, has adopted a free red brick Italian style, and the building has a central tower, covered by a domical roof, and will have an elevation of considerable height. The same architect has a drawing of a Board school. Mr. C. O. Ellison's views and plans of the Liverpool Eye and Ear Hospital, and the Shropshire Eye, Ear, and Throat Hospital, will be looked at with some interest, though perhaps not regarded as perfect models of arrangement. All rooms have a separate connection with foul-air chamber; and we notice in one case the fresh air is introduced at the sides of the windows, the woodwork of which form channels. A detail of a self-acting ash-screening closet (Morrell's patent), illustrates an economical arrange-

ment, in which unscreened ashes from fire-place may be thrown in, and by the inclined screens the fine ashes only are discharged on the faeces. There are three openings provided, one for emptying vault or removing the pail, another for removing the cinders, and the door at top for throwing in the ashes. The Sanitary Appliance Company are the exhibitors. The "Quick Charging Siphon and Pneumatic Sewer Ventilator" are the names of appliances illustrated by drawings by M. J. and L. H. Adams. The former is for flushing purposes, and appears to be an effectual means of applying a siphon. The "Charcoal lung or punkah" is another interesting model of an appliance for sick-rooms. It is composed of a kind of sheet or netting of hempen strands, with a cylinder at the top which is charged with caustic soda. This liquid drops into a trough in which the sheet or netting dips at its upper part. It is thereby constantly kept charged with fluid, all excessive of moisture being drained off by another trough at the bottom. The carbonic acid and sulphur gases are absorbed by the alkali. A drawing shows the same principle fitted to a van for the purification of the underground railway tunnels. Trays of slaked lime with water tank over are the means employed. Amongst other drawings we see a series of sections and plans illustrating a theatre at Brussels, the "Royal de la Monnaie," drawings of a sea-water vessel for conveying seawater to London, a system patented by John Hayes, C.E., and Mr. W. L. Vernon sends some large plans and photographs of Hastings and St. Leonard's, with statistics relating to the climate, health, and drainage of these watering-places.

THE WATER QUESTION.—XII.

CAPACITY OF RESERVOIRS.

A RESERVOIR to hold temporarily a glut of water, and discharge it gradually, may be called a dam, to distinguish it from a reservoir proper, to equalise the flow of water during long periods of time. Whether a reservoir proper or a dam be made in any position where it may be desired to place the land under a system of water conservancy, will always depend upon whether in that position or within reach of it there is a demand for a general supply of water the year round, for houses, or manufactures, or irrigation, or for power away from the stream itself; or whether a demand would be created by first establishing a means of supply. In many matters of trade the supply waits upon the demand, but in water supplies the contrary has been found to prevail, and not in water supplies only; and in taking measures to secure any portion of the uplands or midlands of a river basin from taxation or contribution to funds to be expended in preventing floods in the lower lands by making upon the land itself such works of water conservancy as may be sufficient for the purpose, it is advisable to consider whether in every case where a dam only may be necessary, it may not be profitable to make a reservoir in such manner, and of such capacity as will be sufficient not only for the one purpose but for both, because, for any given quantity of water, within certain limits, it is more economical to store it in one reservoir than in two. Both purposes, however, cannot be economically provided for in one reservoir where the demand for water supply is equal to the available quantity yielded by the drainage area appropriated. When this is so, and the storage room is duly apportioned to the drainage area, the necessities of the case require that as much water as possible shall be kept to meet a drought, and, therefore, the reservoir might be full

or nearly so, when a great rainstorm occurs, and in such a case a dam becomes necessary, in addition to the reservoir; and its position should be below the reservoir; otherwise, a flood-water channel along the margin of the reservoir will be necessary; but when made below it the dam receives the flood waters which pass over the waste weir of the reservoir, and lets them go down the valley in any regulated quantity desired, provided that be sufficient to empty the dam before another great flood occurs. Where, however, the demand for a water supply is not equal to the whole available quantity from the appropriated drainage area, one reservoir may be made to serve both purposes, at least until the demand for water supply amounts to the limit of supply.

In the first place, however, it will be preferable to consider here the two cases separately, and first that of a reservoir for the supply of water for any purpose.

The storage capacity of a reservoir large enough to equalise the flow of water over a long drought, or two or three shorter ones with intervening winter rains of less than the usual amount, and so that the annual rainfall is made to yield its daily average quantity throughout long periods of time, can be found when the past rainfall daily for a long time has been ascertained, the number of dry days in the future being assumed to bear the same relation to wet ones as they have done hitherto, and that the past average yearly quantity of rain will continue the same; then the capacity of any reservoir may be easily found, being measured by the longest period of defect of supply into and discharge out of the reservoir.

It is, therefore, calculated on a basis altogether different from that upon which the space is to be calculated which will be sufficient to receive and hold temporarily, and discharge regularly, an excessive flood of water. Such a reservoir is most economically proportioned to its drainage area when it is of that capacity which is sufficient only to store and equalise the flow of the rainfall of three or four of the driest years coming together, and this has been found, by examination of numerous tables of rainfall, extending over a long series of years, to be about one-sixth less than the average of all the years, and therefore is ascertained by first finding that average from the records of any particular locality, and deducting from it one-sixth part, which leaves a depth which can be economically dealt with. Thus if 42in. be the average rainfall, 35in. will be the depth to reckon upon. From that is to be deducted the depth evaporated, absorbed above the reservoir and given out below it, and that entering into the growth of vegetation. All these sources of loss are sometimes together called "evaporation" simply. This varies with the nature of the ground on which the rain falls, on the form of the surface, and on the humidity or the dryness of the air in general of the locality, and this latter quality varies much in different parts of the country; but the average "evaporation" from all kinds of surface and all localities in England and Wales is estimated to be very nearly 14in. in depth. If it were 14in. where the rainfall to be dealt with is 35in., the available depth would be 21in. in a year, and, in the absence of exact measurements in every part, that depth would be supposed to extend over the whole area draining down to the site of the reservoir. It may not be so where the area is very extensive, and this may have been one of the reasons why expected quantities of water have sometimes not been yielded by a drainage area of given extent; but it is the nearest approximation to the truth which can be made, and some concession towards it may be considered to be made in deducting one-sixth from the known average rain-

fall of one or two places in the area; although in some cases that quantity has been found actually to pass over the waste weir of a reservoir, thus furnishing a direct proof that with such reservoir-room as has been there adopted that part of the water could not be stored.

In waterworks practice the available quantity is conveniently reckoned per thousand acres of the drainage area. Upon an area of 1,000 acres a depth of 21in. of water would yield an average daily quantity of

$$1000 \times 43560 \times 1.75 = 208,800 \text{ cubic feet,}$$

365

of which about two-thirds might be used for supply to houses, manufactures, or for power away from the stream, or for irrigation, leaving one-third or thereabouts to the stream itself; or rather, this latter would be first apportioned, leaving two-thirds for other purposes, and the apportionment would stand thus—

$$\begin{array}{rcl} & 208,800 \text{ c.ft. per day} & \\ \text{One-third} = & 69,600 & \text{,, ,. to stream} \\ \text{Two-thirds} = & 139,200 & \\ & 6\frac{1}{2} & \end{array}$$

870,000 gallons per day for supply,

and so on per 1,000 acres, within limits, defined by our knowledge of the real average rainfall over any area, the certainty of the calculated average increasing with the number of places of observation over a given area, but becoming too uncertain for use when the area is very large and the places of observation few.

The quantity above set down for the stream would render it more powerful in dry weather than it would be without a reservoir. The average flow of the stream in this case during dry weather would probably not be more than two-thirds of the quantity above stated, for a great number of measurements of the dry-weather flow of streams has shown an average of about 30 cubic feet per minute per 1,000 acres of the drainage area. This, no doubt, varies with the nature of the ground from which the water flows, being greater or less as the ground is more or less absorbent. Where the ground in the upper and middle portion of a river-basin consists of chalk, oolite, or sandstone the dry-weather flow forms a larger part of the whole quantity flowing off the ground than where it is of hard and impervious rocks, with the steeper surfaces which always accompany those harder rocks; and the kind of ground which affords a medium dry-weather flow between these extremes is that which consists of alternate formations of sandstone and shale, or of oolite and lias clays, in either case covered in parts with clay and gravel.

The rainfall observations, if sufficiently numerous, will show on an average of years that where the annual quantity is great the number of rainy days is greater than in those parts of the country where the rainfall is comparatively small [this is not, as it might seem to be, a necessary consequence], and so, although more water per day is discharged from a reservoir per 1,000 acres of its drainage area in the former situations than in the latter ones, the loss of water is oftener replenished, and in proportion to the frequency of this action the capacity of the reservoir may be smaller. The experience in England during the last 25 or 30 years has been that, in order to equalise the flow of water day by day during three or four consecutive years of least rainfall, the capacity of a reservoir should be sufficient to yield about 120 days' supply where the rainfall is frequent, and 240 days where it is infrequent; but it is here assumed that the reservoir is full at the commencement of a drought, whereas it may not be so if the previous winter's rain has not yielded a surplus over the regular supply sufficient to

fill up the reservoir completely, and in this view the capacity should be increased, perhaps, to 150 days' supply in the one case and 300 days' in the other. From a casual examination of Mr. Symons's annual records of rainfall, it appears often that nearly as many rainy days occur in the Southern and Eastern counties as in the Western and Midland counties, although the rainfall in the latter is much greater; but the days set down as rainy in the records include those on which 1-100th of an inch of rain falls, and this is so little that it adds nothing to the run of the streams.

The rainy days, the frequency of which affects the capacity of storage reservoirs are not so numerous. To make rainfall observations more useful in practical questions of water supply, the streams should be gauged at the same time as the rain; but as things go, the way to the truth of a thing is through a multitude of blunders on questions of fact—facts quite easily obtained if political questions did not stand in the way of the health of the people, or rather, it may more properly be said, if the health of the people were not of secondary consideration in politics to some others of less worthy ambition. The facts ought to be established at the public expense, then opinions founded on them would afford sufficient scope for the emulation of practitioners in this matter as well as in some others. However, in this particular matter, the last quarter of a century's experience has shown that a reservoir may be depended upon for a supply of water in dry seasons if its capacity corresponds with the above statement, on the testimony of those engineers who have had the greatest experience in the matter. If in the example where 21 in. is the available annual depth of water over the area of 1,000 acres, the proper number of days of supply were, from its position, 180, the capacity of the reservoir would be

$208,800 \times 180 = 37,581,000$ c. ft.
Deduct the dry weather
flow from 1,000 acres at
30 cubic feet per minute 7,776,000 c. ft.
22,808,000

or, 30 million cubic feet capacity, which is at the rate of 30,000 cubic feet per acre of the drainage area.

BRISTOL AND GLOUCESTERSHIRE ARCHAEOLOGICAL SOCIETY.

THE meeting of this Society, which commenced on Tuesday week as reported on p. 102, was continued on the Wednesday and Thursday following. On Wednesday morning, the members set out in carriages for an excursion which comprehended St. Briavels and Tintern. The curious little village of St. Briavels afforded scope for much investigation, the church, which is a handsome structure, being, however, only second in point of interest to the Castle, which is a mere ruin. According to Giraldus, the castle was built in the reign of Henry I., by Miles Fitz-Walter, Earl of Hereford, to check the incursions of the Welsh, and to strengthen the authority of the Norman kings in this part of the country. Fitz-Walter appears to have been the first constable of St. Briavels and warden of the Forest of Dean. His eldest son, Roger, was the founder of the Abbey of St. Mary de Bene, at Flaxley. It is recorded that King John paid a visit to the Castle in 1207, and on four subsequent occasions. In 1205 this monarch conferred the constableness upon John de Monmouth, and Bigland, in his county history, arranged a table of his successors, of whom there were 27, the last holder of the ancient office being Henry Somerset, Duke of Beaufort, from 1811 to 1878, since which time the duties have been undertaken by the Commissioners of Woods and Forests. Houses have been built close up to the edge of the old moat, the greater part of which has lately been drained, from sanitary considerations. The castle is on a sharp shoulder, not on the summit of the hill, and it is constructed of old sandstone

brought from St. Briavels Common, about a mile distant. The double tower of the gateway entrance is still inhabited, but the remainder of the building is in ruins, and many of the walls, through dilapidation, will ere long be level with the ground. Inside the gate on the right is a fine old kitchen, the chimney being nine feet wide, with an iron plate bearing the arms of Queen Elizabeth. The walls are nine feet thick. The original dog-wheel, inside which the dogs ran to turn the spit, still remains. The roof of the twin towers is no longer weather proof. Its few remaining rooms will soon cease to be habitable, and the tower itself will, unless repaired, soon be destroyed. The Rev. W. T. Allen acted as guide to the party, and he explained some of the leading features of the castle, and also gave particulars respecting the church. Leaving St. Briavels the archaeologists proceeded to Tintern, making a halt on the way at St. Margaret's Grove for the inspection of a portion of Offa's Dyke. They also stopped occasionally to enjoy the magnificent prospect. At the Beaufort Arms Hotel, Tintern, luncheon was provided, and afterwards the Abbey was visited, and the ruins, which are pretty familiar to tourists, were once more enlarged upon by Mr. T. Blashill, who dwelt upon the remains of the pile in an interesting manner. The society left Tintern for Piercefield Park, where they were entertained by Mrs. Clay, and then they re-entered their brakes and proceeded to Chepstow.

At the evening meeting, Mr. W. C. Heane, contributed a paper on "The Grange, in the parish of Flaxley." He said the Grange estate, together with a farm adjoining it called Saint White's, were parcel of the possession of Flaxley Abbey. They were in the parish of Flaxley, but formed outlying part of it, being separated from the mother parish by the parish of Little Dean and part of the Forest. The Grange itself was a three-storied house of Tudor, or perhaps Jacobean, architecture. Nowhere on its walls could a date be seen, nor had he found any mention of the building of it. It gave one the idea of not having been completed, but as if it had been intended to build the house to form three sides of a square, with a quadrangle in the rear, and that the third side or wing was never built. There was a tradition that part of the house was burnt down, but he could find no evidence of this. The house was situated in a pleasant valley and was formerly surrounded by trees,—elms and firs, a few of which still remained. It was fast becoming a ruin, as no care had been taken to keep the roof in repair.

Mr. T. Henry Middleton contributed "Notes on the Church of Micheldean." No part of the existing church, with the exception of the font, appeared to be earlier than the beginning of the 14th century. This earlier period, which belong to the Decorated period, consists of a somewhat narrow nave with a south aisle, at the west end of which stands a tower and spire, and opening into the tower, on the south side, there is a small porch. On the north there were originally two Decorated aisles, but the northernmost of these has been rebuilt during the Perpendicular period, probably to gain increased width, when Robert Gryndour founded his chantry here. The eastern part of the chancel is modern, and a vestry has been added at the north-east. A number of modern windows have been inserted of various styles, in some cases not in accordance with the date of the work around them. On the whole, the church is a fine and interesting one, in spite of the loss of its fittings, and the thorough "restoration" it has undergone. In the tower there is a fine peal of bells, on which appear the following inscription:—"Success to the Rudhills of Gloucester," "Peace and good neighbourhood," "God preserve our Church and State," and various others. The earliest feature of the former church is the font, which is Norman, and tube shaped. The upper half has been lost, and the remaining half is turned upside down, and has the basin cut in what should be the base.

On Thursday morning the farewell meeting of the society took place at the Beaufort Arms Hotel, under the presidency of Sir John Maclean. It was resolved that the next place of meeting should be at Stow-on-the-Wold, and that the selection of president be left with the Council.

At the close of the meeting the party had an excursion which comprehended a visit to Lydney Park and Speech House.

Some of the members inspected the old church at Lydney. The structure, in the Early English style, has chancel, nave, and aisles, and a square tower on which stands a steeple that forms a prominent object in the landscape for several miles around. There is a well-preserved cross on the summit of a pyramid of stone steps in the centre of the town, and in olden times the priests used to preach from here.

At Lydney Park Mr. Bathurst received the archaeologists at the Higher Camp. Inside the mansion the party inspected many remains found in the locality, and then Canon Searth gave some particulars of the camps and the remains of a villa discovered in the park. He said they had three points to deal with: the first was a small camp that seemed to have been an outpost, and was probably occupied long before the Romans came. That was separated by a valley from the large camp, and they would follow the Roman road to it. It had been denied very positively that it was a camp at all, but he thought anyone would see it was not only fortified, but very strongly fortified, and unfortunately for the strong authority Professor Hubner, who denied it was a camp, he never was on the ground, and he had found fault with Mr. King for making the assertion in his book, and he had said all previous writers were in error. Having been over the ground five times he (Canon Searth) knew pretty well the fact, and he could say it was strongly fortified at the only assailable point. He then adverted to the remains of the temple, and said it was of the ordinary plan of a Greek or Roman temple. The house, too, was of the plan of every Roman dwelling, all built round the central court, generally the principal chamber in one of the sides of the square, and a number of small chambers going off on each side, and a cloister running round the principal court. There was ample accommodation for bedrooms, and they were content with less space for sleeping than people were now. The place evidently belonged to a person of some importance, as no one would have had a building of that kind unless he was a person of distinction. It had not been shown that he was the priest of the temple, and all he could say was, if the priest lived there he had got a very good parsonage. In the temple an interesting pavement was opened, and the place was stated to have been built or restored from the offerings at the shrine of the god Noden, to whom there were votive tablets. The question arose, who was the god Noden? He was not in the Roman pantheon, but it was well known the Romans adopted any local god they found. Antiquarians were in doubt as to who Noden was; some thought he presided over physie, others thought he presided over the growth of corn; and others, again, said "No, he presided over the Severn and the Wye," and the Romans shrewdly conjectured the man who had command of the Roman fleet lived there. It was not at all improbable the occupant of that villa was in communication with Caerleon, and had something to do with the vessels of supply then anchored in the Severn. They had there not only the villa perfect in form, but the temple perfect, the bathing arrangements, and the chambers of the priest probably, and all surrounded by a fortified inclosure. At some distance was the reservoir which supplied the baths, as the watercourse had been traced.

The party, at the conclusion of Canon Searth's address, proceeded to view the remains which he had described, and then they were entertained at luncheon at the Old House by Mr. Bathurst.

The party next started for the Speech House—so called from its being intended for the use of the ancient court of "The Speech." It is a substantial building situated on the flat top of Speech House Hill, 572 feet above the sea, and is stated to have been commenced shortly after the passing of the Act for the preservation and improvement of the Forest of Dean in 1668, but it was not finally completed until 1680. There is an inscription cut in the lintel of the stable door bearing the date 1676, while over the front entrance leading to the court-room is an escutcheon bearing the initials and crown of Charles II., with the date of 1680. The uninclosed ground upon which the building stands is called sometimes "The King's Walk," after the Merry Monarch, and other walks are named after distinguished personages. The court room is at present the only official portion of the house, and is used between court days in summer, when there are several visitors, as a dining-room.

After leaving the Speech House the members separated in different directions, some going by way of Gloucester, others across the Severn Bridge, and the proceedings in connection with the Chepstow meeting of the Bristol and Gloucestershire Archaeological Society were brought to a termination.

PRACTICAL NOTES ON PLUMBING.* VII.

By P. J. DAVIES, H.M.A.S.P., &c.

TAFT FLANGE AND BLOCK-JOINTS—THE TAFT.

THE taft is after the style of the copper bit-joint, so far as regards its shape, but is made with coarse instead of fine solder. These joints may be made by the unskilled workman; in fact, some plumbers call them the "duffer's joints," and, in a measure they may be right; but, nevertheless, that does not alter the quality of the joint, and I must tell these facetious ones who choose to dub them by that ignominious title, that, when properly made, they are four times the strength of the so-called plumber's-joints, often made by those who run them down. Let us examine this joint.

Fig. 32 shows in section the general shape this

joint is made. The flanged part E, is first opened with the turn-pin to the desired width, then the outer edge is worked back with the mallet or otherwise, to the shape shown between E K J (more often as at E L M, by the skilled and unskilled workman).

On turning it back when doing the flange in this manner, only open with the turn-pin very gradually; by adopting this precaution, you may, with your mallet, &c., thicken your pipe just as you please; but I must contend that it is not practically necessary, as the solder runs down and unites the ends or sides of the pipes at these intersecting points, thereby causing them to become one solid mass of metal; but should there be the slightest objection to this point, then go to work and make the point as at Fig. 33.

Here the flange may be knocked over to as thick again as the pipe, and the spigot end, or B, not allowed to enter quite so far as that at Fig. 32. The preparing of this we will for the present let stand over; but, at any rate, *let it fit well*. Next the soldering.

Here is a very great advantage gained: for, in the first place, not more than a quarter of the solder is required about the actual joint to obtain the same strength, which I, as an engineer and plumber, together with some of the very best authorities of the day, on the strength of lead pipes, &c., say that it is as strong as any other part of the pipe: in fact, when testing this joint, not one burst within $1\frac{1}{2}$ in. of the joint. The pipes used for these experiments were:—

$\frac{1}{2}$ in.	from No. 14 to 30.
$\frac{3}{4}$ in.	„ No. 22 to 42.
1 in.	„ No. 30 to 60.
$1\frac{1}{2}$ in.	„ No. 42 to 52.
$1\frac{3}{4}$ in.	„ No. 48 to 84.
2 in.	„ No. 96.
4 in.	7lb. to 12lb. to the foot made.

There were from 40 to 50 joints made by myself, simply as a test of economy. I shall

* All rights reserved.

give the result in pounds to the square inch when treating of the strength of lead pipes.

There is also another advantage attached to using the taft-joint—viz., you can employ almost anything in the way of solder, or, if you like, can burn the joint with lead as follows:—Place a small wad of blotting-paper at about A, (or a piece of rag tied to the end of a piece of string, threaded through the pipes), and fill up the pipe with sand; then prepare the end of B, place it in as shown, and send some more sand down this pipe to about B; you can get it solid by letting through a few shots just to run the sand down. Next fix a collar round the pipe A, and bank it up with sand to about E; then, by first wrapping a little piece of sheet-lead round the edge of the flange to the desired height of the joint, you can with sand bank up the outer part of the sheet-lead and run your joint as follows:—Take a ladleful of nearly red-hot lead and keep pouring it round the joint until the pipe and lead are thoroughly amalgamated; have a small stick to push into the hot lead, to try if it is quite solid should be used. Your joint is now burned together. Caution.—Take care that your pipes are thoroughly fixed independent of each other, or they will part in the burning. Force the sand out with a force-pump, or as best you can. I did not intend to describe lead-burning here, but have done so to show that any kind of solder, or even lead, can be used to these joints.

FLANGE.

Fig. 34. These joints, in shape, are exactly the same as the taft joint, the difference being that the joint is made on a kind of base, say the floor

boards, or in cisterns, roof work, &c., as shown at F, Fig. 34; there is also used by some plumbers a flanged piece of lead, as shown at C; this is for the purpose of extending the size of the joint, and to save turning the end of the pipe so far back; it also prevents the solder running through the boards, should they be cracked or otherwise bad.

BLOCK JOINTS.

Fig. 35. These joints somewhat resemble the flange joints, excepting that the flange C is first worked or knocked into the hollowed block, as at L C H, and shaved; then the end of the pipe is shaved from E to L, and pushed up through the prepared flange. Take the turn-pin, and open this end, being careful not to drive the lead too hard against the flange. Shave the inside. Now prepare the pipe B, and be sure that your shaving is long enough, as those not acquainted with this joint are apt to be deceived. All being ready, proceed to solder your joint in the following manner:—

Take a ladleful of good hot solder, and splash it on as quickly as you possibly can, to get up the heat; wipe the joint by taking one good sweep round with the left hand, take the cloth in your right hand, and begin where you began with the left, and, with another good sweep, come round to where you last left off; then from the top of the solder bring the point part of the cloth to the same line as the other part of the joint and off. Or, if you can, get at your joint with one hand, wipe all round at once without lifting your cloth, and finish as above. Part your surplus solder, and pick it up ready for another joint.

PUTTY JOINTS.

Fig. 37. Our work on joint-making will not be complete unless we speak of making putty joints. I have particularly noticed that many plumbers are in the habit of making these joints without sufficient care. They think that because it is only a putty joint, anything is good enough.

I contend that this joint requires quite as much care as other parts of the trade; for what is worse than a leaky joint to the arm of a closet-basin, and is there any leaky joint so numerous as the putty joint.

To make a good putty joint, let the pipe enter the arm of the basin about 1 in. or so. After this, see that it is perfectly dry and free from water; then take some kind of paint, and paint it well inside and out, after which take some stiff red and white-lead putty (many plumbers use ordinary putty, but it will not last the time or stand quarter the pressure), and with this make your joint to the shape of Fig. 37. Next take a piece of calico or canvas, about 3 ft. long and about $2\frac{1}{2}$ in. to 3 in. wide, and rub the paint tool over same; then wrap up the joint from A to B by winding your wrapper carefully round and round, true and tight; then take about three yards of middling thick twine, and make same good to A E, and then wind it tightly round your wrapper, as shown, until you come to B F, after which make it fast as best you can—a good plan is to tuck the end under, as shown at J. After this, rub the paint tool over same, to protect the twine from dampness. Care should be taken not to disturb this joint after it is made.

(To be continued.)

RESTORATION AT ST. ALBAN'S SINCE 1877.

(Concluded from p. 69.)

NOW that "the hurly-burly's done," which I arose about that matter (the high-pitched roof), I may mention some important discoveries which that work disclosed. First, it was found that there had been two high roofs over the nave of St. Alban's, one oversailing, erected by Paul of Caen, the Norman builder, and another with parapets, most probably constructed in the Decorated period, presumably in the time of Abbot Montmore, when the fall of some Norman compartments led to large reconstructions in the nave. The marks of both these roofs had been discerned, by the careful eye of Mr.

Chapple, on the western face of the tower, when its reparation was under his hands, and as we could not, and would not, destroy the later parapets, though such a course had been suggested by no less an authority than Mr. Street, the new roof was laid within them, on the Decorated lines. I may mention as a parallel instance of a second high-pitched roof, during the Medieval period, a fact, which our discovery at St. Alban's led me to fully investigate at Peterborough; that noble church had once a lofty central tower, the work of Abbot William de Waterville between the years 1155, and 1175; it was three stories high, and of very rich Late Norman work. The tower of Castor Church, four miles west of Peterborough, a parish closely connected with the Abbey and Cathedral (my father was its last rector in right of the Bishopric), has been thought to have been a copy of the great tower of the neighbouring Abbey Church, which, in that case, must have been splendid in the extreme, Castor being perhaps the most beautifully rich Norman tower in the kingdom. This great tower at Peterborough became so insecure that it either fell, or was removed—most probably the latter, or there would have been a greater crushing of the work below than now appears, and a Decorated tower, some few years later perhaps than the St. Alban's Decorated parapets, was built in its stead. At that time parapets were added to the nave at Peterborough, and precisely the same kind of roof was erected which we now see at St. Alban's, the line of the original higher, and oversailing roof being still to be distinguished on the back of the central gable of the Early English west front, which was arranged to accord with the older form of the roof which it terminated. A second discovery at St. Alban's was that the ceiling, which looked so well at a distance, was a very inferior imitation of a panelled roof discovered beneath it, sufficient of which was left to give authority for the ceiling, with its singular oblong rectangular panels, which has now been restored in oak, and only awaits the skill of a L'Estrange, or a Gambier Parry, to reproduce effectively its ancient colouring. A third discovery was that on a corbel, which formed an integral portion of the low roof, the probable date of which had been so much discussed, were found the initials "I.W.," marking it as the work of Abbot John of Wheathampstead; so it is now clear that when he lowered the aisle roofs, in order to fill the Norman Triforium arches with tracery and stained glass, he also lowered the great roof correspondingly. At the earnest desire of Mr. John Scott, and some others, a part of the roof, so lowered, has been preserved over that portion of the constructive nave which forms the choir, and it can now be conveniently seen by those who wish to examine it. During the last four years, then, the great work of raising the dangerous portion of the nave to the perpendicular, which will always have a deep interest as the last great mechanical work of Sir Gilbert Scott, and restoring all around it, has been accomplished; the nave-roof has been restored; the Lady-chapel has greatly progressed towards completion, the horrible pathway through its neighbouring chapels has been abolished, and a vast improvement effected by the acquisition of the property at its east end; now, through the munificence of one of our great benefactors, some beautiful areading destroyed, and cut away, is being restored, and replaced, while the Corporation of London are restoring, and will, I understand, fill with stained glass, the wonderful window at extreme east, the side windows having been already restored by the kind exertions of Lady Salisbury and some "ladies of Hertfordshire." The Freemasons of England offered to provide a recessed below the great east window, but there were difficulties in the way of accepting the gift, which will now, I believe, take the form of a cathedral pulpit. All we can hope is that the Lady-chapel will soon be so far completed as to serve the purpose of a Morning Chapel, an adjunct which no Cathedral Church can well dispense with, and that it may soon be opened to the rest of the building, and befloored with suitable paving. I have but little time left; already I have found that I have had more to say than most audiences would have the patience to hear, but I must refer for a moment to a very important work now in hand—the preparation of the stalls for the cathedral choir. These are being worked from a very beautiful design by Mr. John Scott in oak, the material

which Edward II. granted from the royal forest for the construction of their predecessors. When the return stalls are completed, one side will form a memorial to the late Archdeacon Mildmay, and the entrance doorway, and its surroundings, will be provided as a memorial to Captain Campbell, our good Bishop's lamented son-in-law, while the other stalls will be the liberal and valued gifts of some generous benefactors. Let us hope that the side stalls, and all that is needful to get the choir into cathedral working order, may shortly be provided. I need hardly say now, after all that I have spoken, written, and published on choral arrangements generally and those of St. Alban's particularly, that I am not the architect of the plan just undertaken for placing and working the large organ. It has been put, I believe, where we shall see it, from the pressure of that necessity which knows no law: I regret that an opportunity has been let slip for making some satisfactory permanent arrangement of this organ, such as I have often recommended, but I am assured that we shall have before us, or rather behind us, only a temporary arrangement to preserve, and restore to its use in the choir, our very fine instrument. I can hardly call the opportunity which has been lost, a golden opportunity, however, for that has not been of late a very appropriate epithet in describing our opportunities at St. Alban's, in fact, so serious has been the unlooked-for pecuniary embarrassment of that committee of which I have the honour and pride of being a member, that had it not been for the timely assistance of some generous subscribers, who have been friends to us in our need, I could only have hoped to have addressed you to-day by an application to appear through a writ of Habeas Corpus. I was able to assert, without I trust vain boasting, when I last addressed you, that up to that date, no mistakes had been made in our works of reparation, and I think I may say that the same sound and careful principles of restoration have guided our committee in their deliberations, and their orders, during the past four years. We are, however, now witnessing, for good or for evil, a new departure. I am myself very sanguine that the balance will be largely in favour of the good, but two archaeological proverbs may here be quoted—viz., "that you must not look a gift-horse in the mouth," and that the "proof of the pudding must be in the eating." A large share of responsibility will now be shifted, so far as the restoration of the west front, and its surroundings, are concerned, from the shoulders of that "multitude of councillors" in which a still older proverb tells us "is safety," on to the shoulders of one of our number, one, however, whose generosity we must all admire; one, who, among the army of amateur architects, stands in the foremost rank; one, who, through evil report and good report, will do the great duty he has so nobly undertaken for the Church of England, and for this county and diocese, with all the patience, skill, and care that is possible in man. Already we have an earnest that the noble design of John de Cella will once more be partially seen in the exact restoration of those three grand porches, which were its most glorious and unique feature. If our faculty committee are to be blamed then for allowing so great a work, and the opportunity of so great fame, to pass from their care generally; if the noble president of this Architectural Society and myself are reproved for severely proposing and seconding, in that committee, the resolution which handed over this work to the purse and to the care of Sir Edmund Beckett, our apology, if one is needed, must be that other benefactors failed us in the day of necessity, and that, if mischief befall, our committee must plead their poverty, and not their will, consented. I might, perhaps, conclude with a funeral oration over John of Wheathampstead's Perpendicular west window; but it is better to hope for its resurrection, if the means, that great difficulty at St. Alban's, can be found. It might now well form the eastern window of a building to be used as a library, Chapter House, and vestries, to be hereafter erected in the place of the ancient sacristies, on the south of the presbytery. This would look much like the arrangement of the chapter house at Exeter, and would be a most valuable and necessary adjunct to our cathedral. If, then, the defenders of the fallen window would lay down their arms, and lay down the dust besides, we might see our

deeply interesting and historical window restored to its dignity, and to us once more.

CALCULATOR OF MEASUREMENT OF PACKAGES AND TIMBER.*

TWO bulky volumes, by Mr. Manekji Kavajji Todivala, of the British India Steam Navigation Co., are certainly evidence of the growing magnitude of Anglo-Indian commerce. The large number of packages shipped make it necessary that their solid contents should be accurately ascertained in fractions of an inch, and the Chamber of Commerce now requires all packages, bales, &c., so to be calculated that all fractions are to be taken into calculation. Merchants and shipowners have adopted this system of exact measurement in their own interests; but it appears that shippers are in the habit of avoiding the fractional computations as too tedious, and in order to arrive at quick results, they adopt a rough and ready method, by which all fractions are either shifted and interchanged, or taken as whole numbers. It will at once be seen that this custom favours the shipping-owner at the cost of the shipper and the owners of packages. When, say, there are 100 cases, a difference of a fraction of an inch, say 33ft. 9in., makes, at £3 per ton, no less than £2 10s. 7½d., which the shipper has to pay in excess of one shipment. Of course such a loss on the part of the shipper tells in favour of the shipowner. The examples given show how these differences work out in the case of shifting the fractions, or taking the whole for the fraction. The greatest loss is experienced in the latter case, and when a shipper sends from 1,000 to 10,000 packages, the loss is very heavy. Mr. Todivala's "Calculator" is the result of an endeavour to obviate this great disadvantage which the shipper of goods experiences, and we are sure his two years' labour in compiling these tables entitle him to the best thanks of the mercantile world. The tables have been examined and certified to by Professor Hathornthwaite, of Elphinstone College, Bombay, who says that out of many tests he discovered only one error in the second place of decimals. The payers of freight are at present heavy losers by the tolls and expenses levied on packages by commission agents, and as the author says, "this custom must in the aggregate, and on hundreds of thousands of packages, tell heavily against the profits of shippers to and from India, and be adverse to the just interests of Anglo-Indian commerce." The tables given, which fully occupy the nearly 800 pages of each volume, are equally serviceable to the merchant or shipper having business with England, wherever, in fact, English measurements are used. To the shippers of this country we are sure accurate calculations will be sooner or later demanded, and in the interests of trade everything which facilitates correctness of charge must be welcomed. The tables proceed by increments of a quarter of an inch, so that packages whose dimensions vary from 6in. to 8ft. in length may be calculated at a glance of the table. Thus if it is required to find the solid contents of any package, say 3ft. 4in. by 2ft. 1½in., and 1ft. 1½in., the reference is first made to the top of the page, where the least dimension is found; the next dimension of 2ft. 1½in., is found at the top of one of the columns, and the length of 3ft. 4in. will be found in the centre column. Opposite the latter figure, and under the breadth, the required solid contents is found, or 7ft. 11in. .02dec. Several examples are given to show how the references are to be made, which are extremely easy. The tables increase by quarter inches, so that a package measuring 6ft. 6in. long by 3ft. 11½in., and 2ft. 6in. deep, may be directly taken from them, but when all the dimensions exceed 2ft. 6in., the solidity may be obtained by a very trifling calculation.

Not the least useful feature of the book is the service it may be made of in calculating timber, scantlings, and the solid contents of casks, thus saving an immense amount of tedious labour. The greatest advantage of properly-computed tables is, however, that accuracy is insured as well as time saved, and every attempt made to lessen arithmetical

* Calculator of Measurement of Packages, Timber, Casks, &c. In Two Volumes. By MANEKJI KAVAJJI TODIVALA, Shroff, British India Steam Navigation Co., Bombay.

labour, and, at the same time, to give correct results, is worthy of all praise, and with this assurance we heartily recommend Mr. Todivala's comprehensive volumes to the attention of all readers concerned in mercantile transactions.

SUGGESTIONS IN DESIGN.*

BOOKS on ornament have been so abundant of late years, owing chiefly to the impetus given to artistic manufactures that any new work on the subject ought to be particularly good. To be of any real use to the designer or art workman, the ornament should be applied to the purpose for which it is designed, and ought to be the work of men who have thought out the requirements of manufacture and the adaptation of material. A scattered collection of fragmentary ideas and fancies can have but little value to the designer in ceramics, metal, or woven fabrics, and it is to be deplored so many undertake works, the practical use of which is very doubtful. We have on our table a bulky folio volume by Mr. John Leighton, F.S.A., the letterpress of which has been contributed by Mr. James R. Colling, F.R.I.B.A. The work has the modest title of "Suggestions in Design," and, according to the preface, the nucleus of the work was prepared so long ago as 1852. However this may be, the book certainly rather indicates the state of art design at the period mentioned, and serves to show the great advances we have made, than to be depended upon as an index of the present state of design. We speak more in reference to the illustrations than the letterpress. It seems rather a pity the authors should have been induced by the success of the first work to redraw the original plates, and add to their number, for every one knows how great a change has passed over ornamental design since the time of the first International Exhibition. Its very principles have undergone a change, for, as the publishers themselves say, the original work was begun when Gothic art, under the influence of Pugin, was paramount—when Owen Jones's "Grammar of Ornament" had not even been thought of.

With these preliminary observations, we are better prepared to examine the work before us, which is handsomely bound and well printed. We may at once say the most reliable and useful part of the book is the introduction and historical account of the styles of ornament. No fewer than 176 pages are devoted to this portion of the work, and every style of ornamentation, from that of primitive races to French Renaissance, is described. The usefulness of these chapters is increased by wood engravings, generally well chosen, illustrating typical examples of ornament of the several periods. In alluding to Egyptian ornamentation, the papyrus, lotus, and palm, and the surface decoration in colour and sculpture, are dwelt upon. In the same manner the types of Greek ornament are introduced by reference to the elements of the architecture, while the author does not omit to mention Dr. Schliemann's discoveries at Mycenae and Troy, as bearing upon the origin of Greek ornament, such as the spiral lines known as the Vitruvian scroll, the fret, &c. The plates illustrating this portion are not so well chosen as might have been expected. The free adaptation of the anthemion ornament, for instance, is not a graceful example in Figs. 1 and 2; the Atlantes are of rather a sturdy type, and the suggestions given for band-enrichments (3 to 10), and the figure for colour decorations (11) are, to our minds, instances of an indefinite kind of ornament that one could not call good Greek. On Plate 9, Figs. 5, 8 scarcely suggest the spirit of the style, and the border enrichments 14, 15, with the leaf and ivy patterns on the same plate, are vague and meaningless in motif. What can we call such a singular conglomeration of scrolls and honeysuckles as that figured on Plate 12, Figs. 1 and 3? In these there is a painful sense of confusion and a want of unity. Some of the scrolls in Fig. 3 are positively contrary to the true principle of joining curved lines; but we pass on. We might take exception to the examples of Roman ornament given on Plate 15, and much better forms are given in the letter-press describing this period. Chinese and Japanese ornamentation

are illustrated by several suggestions, some of them passable instances, but others having little common to those styles. The best specimens are Plate 21, Figs. 2 and 3; Plate 22, Figs. 4, 8, and 10; Plate 23, Fig. 7; and Plate 24, Fig. 4. There are few of the Japanese emblems, the fabulous creatures, as the dragon and the *kirin*; we do not see any representation of those favourite birds of the Japanese artist, the *ho-ho* and the crane, nor is there any good examples of foliage and diaper-work in which he so excels. In the letterpress, we find several outline examples of diapers, which will give the student a better notion of the peculiar beauty of the style. The Indian ornament appears to be chiefly derived from woven fabrics, after which follow a series of examples of Moorish. But Oriental ornament was little understood when these designs were made. The peculiar semi-Greek character of Byzantine is scarcely suggested in some of the designs; Gothic ornament follows, and no less than six plates are given to this period. Some of the designs on Plate 36, Plate 37, and some of the panels on Plate 38 are very feeble. The design for the book-cover, on Plate 37, is much too naturalistic in treatment, and this spirit seems to prevail in other designs. The plate of surface decoration is not up to the mark, and the metal-work is behind the age, and is lumpy and coarse, or too closely natural in rendering. Renaissance ornamentation is the subject of a distinct chapter; the illustrative examples are numerous, though we are disappointed in the selection, and some of the forms would be more strictly called Gothickesque or nondescript. Several plates of inlays and diapers, of what is called blazonry, and a variety of suggestions for floral design, figure composition, and chimerical subjects, make up the book. We are afraid many of these will not bear a critical study. There is an objectionable naturalism in many of them, as in Fig. 3, Plate 39, and Fig. 3 on Plate 90. What is the meaning intended to be conveyed by girls' heads growing out of flowers, or human hands in the form of branches. These and other chimerical ideas and vagaries would have been better omitted altogether. There is much to commend in the descriptive part of the book, and the chapter on floral ornamentation has much to redeem the character of some of the designs. These chapters take into account the architecture of the several periods, and so lead the student from ornamentation, based on structural principles and utility, to other kinds in which the laws of composition are less rigidly enforced. Altogether, the work may be studied as a useful, historical introduction to the subject of ornament.

ROYAL ARCHEOLOGICAL INSTITUTE.

THE annual meeting of the Archaeological Institute was opened on Tuesday, at Bedford, under the presidency of Lord Talbot de Malahide and Mr. Charles Magniac, M.P.; Lord Cowper, the Lord-Lieutenant of the county; Mr. J. Shuttleworth, the High Sheriff; the Duke of Bedford, Lord Tavistock, M.P., the Bishop of Ely, and Mr. J. Howard, M.P., were among the patrons of the meeting. At 12 o'clock the Mayor and Corporation publicly received the members on their arrival at Bedford, the town clerk reading an address which welcomed them to the town and pledged the inhabitants to place every facility at their disposal. The reading of this address was followed by the reading of others to the same effect from the local Ecclesiastical and Antiquarian Society, and also from the Bedford Literary Institute. These Lord Talbot acknowledged briefly, and then resigned the chair—for the present congress—to Mr. Magniac, who delivered the inaugural address. Mr. Magniac urged the claims of archaeological and antiquarian studies to be regarded as a science, and deprecated all idea of treating the congress as a mere pleasant local gathering. He advocated the consolidation of local researches, so as to form the basis of a county history of Bedfordshire, which was still a desideratum, and which could only be accomplished by a concentration and subdivision of labour. He pointed to the results of archaeological inquiry in Greece, Italy, Asia Minor, and Egypt, and to the achievements of Layard and Schliemann in disentombing, not merely long-buried cities, but their inhabitants, their manners and customs; and concluded by expressing his conviction that, by our present researches, we are only paving the way for the scientific reconstruction of past ages. At the conclusion of Mr. Magniac's speech, the members of the institute, and a large number of visitors, sat down to luncheon in the new Corn Exchange. The afternoon was spent in reconnoitring the site of the ancient Castle of Bedford, its keep, outworks, &c., and in an inspection of St. Mary's and St. Peter's Churches, the old Grey Friars, and the other leading features of that ancient town. In the evening there were meetings of the various sections of the congress, when several papers were read.

NEWCASTLE-ON-TYNE.

THE engineering and architectural world have lately had their attention called to this town by the Stephenson's Centenary, the important litigation case of *Angus versus The Commissioner of Works*, and the building of the Chinese gunboats, armed by Sir William Armstrong; Swan's electric light, and other great undertakings, so I trust a few notes on the old and new parts of Newcastle-on-Tyne will not be out of place in your columns; but as they are penned by a visitor, they will be but short.

The hoarding has been removed in front of the Burden Buildings, which has been standing for upwards of six years. The building, which was designed and carried out by Mr. John Johnstone, is one of the finest specimens of street architecture in England or the Continent, owing to its originality and beauty of design. It will consist of about twenty very large shops on the ground-floor, and about 200 rooms above, to be used for hotel purposes, in connection with the old Neville Hotel, which will eventually be pulled down and rebuilt in the same style, including many other old buildings facing the central. Looking down Grainger-street, one sees ranges of buildings worthy of the metropolis. One of these is the office for the Newcastle and Gateshead Gas Company. In Collingwood-street are the new insurance offices by Austin, Johnson, and Hicks, a very handsome front in the Queen Anne style; a little further on is the Town Hall, built about twenty years since, a wretched confusion of old Classic, badly adapted from various works by Inigo Jones, Sir Christopher Wren, and other Classical architects. Looking towards the High-level bridge is to be seen the celebrated old church of St. Nicholas (which is to be the cathedral), and close to which, apparently to insure its early destruction, the corporation are allowing a number of very lofty buildings to be built, the basements of which are principally let to oil and butter merchants. Many of these buildings are very fine, especially the block by Mr. Parnell in the Italian style, and the offices for Mr. Armstrong in red brick and free-stone, finished at corners with corbelled turrets, and small spiral roofs, a clever mixture of Queen Anne and Scotch Baronial. Going towards the Manor Station we notice a wholesale demolition of old property for the new road, which is to open out the new estates at the east end of the town. There is much useless old property occupying valuable sites in Newcastle that should be destroyed (and, if possible, some of the tenants with it).

Making a short cut across these slums, towards the Blythe and Tyne station, one comes upon the New Library, a Classical building designed by the borough engineer, but which should have been put up to competition. From thence one strolls down Northumberland-street, among the cabinet-makers of the North, one of whom, Messrs. Chapman, fitted up the Scotch Arms Restaurant, from the designs of the architect—a building which it is said surpasses the Criterion of London, although much smaller. The next building worthy of notice is the New Museum, on the high road to Edinburgh; a munificent gift to the town and worthy of further comment. Leaving this, one makes way through Jesmond, down roads lined with jerry-built houses, in a bastard Queen Anne style, with everything studied but good design, good construction, and proper sanitary arrangements. Between each main road is a narrow back lane, with a doorway and two loopholes to each house. The loopholes are, one for coals and the other for the clearance of the middens, the middens being a sanitary arrangement allowed by the corporation, consisting of a privy and a dust-bin. Although they are in juxtaposition, no

* Suggestions in Design. By JOHN LEIGHTON, F.S.A., with descriptive and historical letterpress. By JAMES R. COLLING, F.R.I.B.A. London: Blackie and Son.

arrangement is made for the ashes falling on or near the excreta, which is apparently allowed to remain for many months decomposing; and the ash-pits, which are about 6ft. by 6ft. by 5ft., with loopholes or doors near the top, are generally filled with decomposing matter.

Getting tired of Newcastle when the atmosphere is impregnated with chemicals, one naturally makes for the sea-side, and arriving at Tynemouth, one is much interested by watching the steam navies which are working on the new line from Tynemouth to Whitley: the latter place being expected to out rival Tynemouth, on the strength of which houses are springing up like mushrooms, but all on the jerry building system: in many cases one finds 7in. by 2½in. joists to a 15ft. span, and 15in. apart in the clear.

One is also very much disgusted to find how defective the sanitary arrangements are in some of the coast villages; and the inhabitants tell me it cannot be remedied, as most of the owners are on the sanitary boards, and any complaint is simply pooh-poohed by them.

Not being particularly fascinated with Northern sea-side residential architecture, one pays a visit to the Tynemouth Crystal Palace, a very fine building, designed by Masey, of London. It consists of the large winter-garden (without a vestige of winter plants in it, or anything else, excepting the organ, which is a grand instrument, and is well played); and the aquarium, wherein I saw two small dabs and one crab; the hotel, which is not patronised, and the concert-hall, which is not completed. Judging from what one saw, the speculation must be a failure, as the journey to it would be impossible, excepting in very fine weather, the approaches being very incomplete owing to a dispute between the Duke of Northumberland and the Tynemouth Corporation.

There are many very interesting relics of old Newcastle; but they are so fully detailed in the "Guides" to Newcastle that any account would not be worth space. A. V.

GLOUCESTERSHIRE NOTES AND QUERIES.*

THE present number of this welcome serial contains a few notes of interest. The custom of wearing hats in church is made the subject of a note, from which we gather the Puritans persisted in the habit till as late as 1639. A very interesting account of a great flood in the Severn, which occurred in 1696, is taken from the *Gloucester Magazine*, from which it will be seen that that river has been the source of greater floods than any of late years. All the country from Bristol to Gloucester, for some miles on each side, was overflowed, and many villages and bridges destroyed. The loss is estimated at 500 persons. A church at Cardifl was partly carried away, and South Wales suffered much. The account is graphically written in the quaint semi-superstitious style of the period. Another writer has a query in reference to the locality of Kingswood Abbey, and asks whether any remains of it are to be found. The tomb of Edward II., in Gloucester Cathedral, is the subject of an interesting note, and we find an account given of the examination of King Edward's tomb, for the purpose of discovering whether his body was actually interred beneath the tomb. This doubt was set at rest by the discovery of a wooden coffin quite sound, enclosing a leaden one of arched form. Reference is made to Mr. F. S. Waller's edition of the Rev. H. Haine's "Guide to the Cathedral," and the account of the examination of tomb is quoted from the late Mr. Allen's not-book. The note on Richard Furny, Archbishop of Surrey, and a learned antiquary and writer on local antiquities, is interesting; and another, headed "Sepulchral Crosses," furnishes the reader with some information respecting two Gloucestershire crosses, one a grave-stone cross in Brookthorpe churchyard, of the 13th century, and another on a raised tomb in Quenigley churchyard. The writer quotes from Mr. Charles Bailey's paper in the *Journal of the British Archaeological Association*, and, as he states, these crosses afford much collateral evidence of age, manners, and customs, though many fine examples are

scattered in remote churchyards. One of the most interesting scraps refers to the old organ of Uley Church, mentioned in Fosbrooke's "Encyclopedia of Antiquities," and cited there as the model of the old form of instrument. It seems, from a correspondent in *Notes and Queries*, this old organ was removed about 70 years ago, and there are said to be no remains of it. It is said to have lasted from the time of Charles II., and is described by an old inhabitant as a "box of whistles." It was turned with a handle, like a grinding-organ, and was painted blue and buff. Uley Church is an entirely modern structure, and replaced the old one, which had a very ancient tower.

The next note, CCCCVI., upon an old stone pulpit in Pitecombe Church, informs a querist that the only extant portion of this old pulpit has been inserted in the south wall of the chancel. Specimens of Local Dialect, and some remarks on the old south gate of Gloucester, destroyed in the siege of that city in 1643, but afterwards rebuilt, also the note on Fairford Manor and Church, will be read with much interest by local antiquaries. This number contains a steel engraving of "Over Bridge, Gloucester," a structure of one span, the arch having a very flat elliptical curvature. The map of Gloucestershire is a valuable addition to the present part, and enhances the usefulness of the Rev. Mr. Blacker's publication.

"BUILDING NEWS" DESIGNING CLUB.

DESIGNS FOR A SMALL STABLE.

THE designs we have received for this subject are very numerous, and many of the plans show a knowledge of the requirements of buildings of this kind. With regard to external treatment, a few have conceived the kind of building in the right spirit, though among many a rather fussy picturesqueness has been obtained at the expense of simplicity and economy. (1) "Pupil J." has worked out a simple, unpretending plan in a quiet sensible manner, the materials being coarse-d stone, with dark red tiles for the roof, and a little timbering in the coach-house gable. The general disposition of plan is good. The stalls and loose-box form a cross wing open to the roof, which boldly projects, screening the washing-space; a small harness-room connects the stable to the coach-house, the latter has a coachman's room over, access to which is obtained by a stairs. Over the harness-room is a hay-loft. A shoot and ladder in the stable are shown in connection with the loft, and a stove is placed in a recess in the coach-house. The centre pier between the coach-house doors, which are hardly wide enough, is unnecessary, and another foot or two would have improved the stable. Effect is obtained by arching over the washing lobby below. The stairs entrance is in this lobby. (2) "Walter" has many good points in the plan; the stalls and loose-box are similarly placed to the last, and form a projecting gable open to roof, screening the washing-space in front of harness-room. There is a separate entrance to stable for the horses, and the loose-box and cob-stall are well placed at the inner end. A stairs to the hay-loft over ascends from the harness-room, and there is a hay-shoot in a good position. A stove is made to warm both the latter room and coach-house at the same time; coach-house measures 18ft. by 15ft. A Boyle's ventilator is shown fixed over stable, and the external treatment is stone and brick, with plain mullioned windows in a suitable style. The projecting roof over carriage-wash is finished abruptly; a deep corbelling at end would have taken away this appearance. (3) "Jack" sends a piquant ink sketch in a brick style, Queen Anne in spirit. The coach-house is rather narrow, only 15ft. wide. The author follows the same plan as the two first-described, with a small centre harness-room, and horse-washing lobby arched over. One objection is the awkward entrance to the stable; the projecting jamb of the hay-shoot would make it extremely awkward for a horse to turn. A useful stove is placed to heat both the harness-room and coach-house, and we find a loft over the stable, pierced by a ventilating shaft having a cupola on the roof, the coachman's sitting and bedroom being over the coachman's and harness-room. (4) "Walter H." This is a neat set of drawings; the stalls and cob-stall are placed on the reverse

side to those we have been describing, but we find no bin or hay-shoot provided, though there is a hay-loft over. The harness-room, with horse-wash space, covered over by a continuation of the roof, is convenient, and the coach-house has also a covered space for washing carriages. A coil heats the coach-house, and the man's room forms a corbelled gable arrangement above the roof of this part. The style is suitable for brickwork. (5) "Finem Respie" is another well-planned arrangement, with a neat brick exterior; the disposition of stables, harness-room, and coach-house is similar to the first of those mentioned, and the yard is shown inclosed by a wall with manure-pit, &c. A small hay-loft is got in the roof over coach-house, and the stables are ventilated by a louvered turret. (6) "Yarra Yarra" adopts also the typical plan, but has two loose-boxes and a centre stall. The coach-house is narrow, 14ft. by 18ft. deep, and no heating-stove is indicated. There is a loft over both, with a man's room over harness-room. The floor of coach-house is boarded, and Musgrave's fittings and ventilators are provided. The drainage is conveyed by a 6in. socket-drain, bedded in concrete, to a manure-pit. The treatment is unpretending, and the windows too small for light. The case-ments are made to fall inwards at top. (7) "Veritas Vincit" shows a half-timbered building. At one end two stalls are placed, entered from a covered way; at the other end is a loose-box and coach-house, these being separated by the harness-room. This plan is hardly compact enough to be desirable. The most objectionable point is the upper story of lofts, the coach-house being kept low. (8) "Black and White" has a three-stalled stable with covered washing-space, harness-room, and coach-house, between the two last being a wide stairs to coachman's rooms over. The stable has a loft over it. The planning is compact, and the coach-house is only 15ft. by 10ft. In elevation, brick of the simplest common-sense treatment has been adopted. (9) "En Avant" is simply and suitably treated; stable provides for two stalls, a loose-box, and a cob-stall. There is a washing-place, covered, in front of entrance, and the harness-room and coach-house are convenient. A ladder ascends from the stable to the hay-loft, which is larger than necessary. Boyle's ventilator is shown in a turret over. Brick and stone dressings, with Broseley tile roof, are specified, and Cottam's stable fittings are mentioned. (10) "Quiet and Simple." This is a 4-shaped arrangement. The stable shows a small stall for cob, besides the loose-box, and two stalls, and loft over; the coach-house and harness-room form the cross block, a living-room and bedroom being got above, approached by an independent entrance and stairs. Ventilation by a centre shaft is shown above the stable, and the fittings are pretty complete. Old English, with brick and tile-hung parts, and timbered gable, is chosen. (11) "Iota" is a Gothic design in brick and stone, but rather too school-like. The gabled dormers over stable, and the high-pitched gable of coach-house, look out of place. The plan shows an independent entrance to stable, besides one from a covered lobby. The corn-bin and hay-shoot are placed at the end, which arrangement makes the stable longer than need be. (12) "Bonus Hominus" has several good points; the elevation is plain, but characteristic, executed in brick and tile, and the plan is convenient. We take exception, however, to the stable arrangement, in which two loose-boxes—one in the angle—is obtained, besides a stall. The hay-shoot, ladders, mangers, and the stove for heating the coach-house and harness-room are well planned, and ventilation is provided by air-bricks, 18in. from floor, and the upper portions of window are intended to open. "Merit" has a sensible general plan, but the independent loose-box at the end and the passage at the end of stalls are not required. The elevation is generally appropriate. "Nitor" makes his stable the prominent feature, flanking it by a coach-house and harness-room, which appear as low wings. The requirements are fairly provided for. "Tom Finch" sends a characteristic treatment. The harness-room is carried up over an arched washing-lobby, and the upper story is appropriated for hay. It slightly projects on corbels, and is timbered. Two stalls and a loose-box for cob are shown on one side and a coach-house on the other. The roof of the latter comes forward and forms a covered shed for carriage-washing. "Per"

* Gloucestershire Notes and Queries. London: W. Kent and Co., Paternoster-row, E.C.

shows an economical plan, but the details are imperfect. An arched washing-lobby in front of harness-room is made the central feature, and is gabled. There is a loft over the whole, the roof having a ventilating turret. "Alpha" makes also a feature of the grooming-space, which is arched over and made a hay-loft above, the harness-room and coach-house, form two low wings. Two stalls and a loose-box are obtained in the rear, but the roofing of this part is not quite apparent. Details also are wanting.

It would be impossible to comment on all the designs. Many of the plans show fairly-arranged stables, but fail in the details. "Hamlet," for instance, sends a plain inexpensive design with timber and plaster in the upper story, but there is no distinct entrance to harness-room; "June's" design is too expensive, and the separate space for washing horses and the large harness-room are unnecessary; "Vignette" has a simple and compact plan, and one could have wished the details of elevation had been better; "Romeo" has too long a range; "Rex" shows a neat elevation, but is imperfect in details of plan; "Joek" has a convenient plan, but the elevation is crudely drawn; "R. E. S. W." has a plan capable of improvement; the entrance to stable is contracted and awkward, and we cannot admire the elaborate ornamental treatment to gable. "H." has a compact plan, but puts us too much in mind of a town building; the coach-house is narrow. "That's my idea" partakes largely of a gentleman's lodge; the coach-house is much too narrow, and the plan is not compact. "Cede Deo" is a singular plan, with a projecting loose-box, a room for food, and a coach-house 25ft. long. The doorways are not happily placed, and the large covered cleaning-shed in front is excessive. "Gig-lamps" also goes in for a large washing-shed, and details of a rather costly kind in elevation. "Utile Dulci" is fairly planned, but meagre in elevation; "Lancaster" is simple, though hardly well studied in the fittings; and "Good Luck to Your Fishing" has a well-considered plan spoilt by a coarse elevation; "X. L." is rather wasteful in arrangement of feeding passage, and "T. F." in circle is compact if not convenient. We may also name "Fiat," "Bon Ton," "Desire," "Parans," "Will," "Trial," "Ambition," and "Montigue," as arrangements which show a more or less imperfect knowledge of the requirements of stable-planning.

A SMALL CONSERVATORY.

Few of these meet our expectations. "Jack" is the first in both plan and design. The plan shows an oblong conservatory, projecting from drawing-room, 18ft. 6in. by 11ft. 6in., with gabled projections at the end; the main roof being hipped back on the same plane. One projection contains the entrance, and the other is intended for an aviary and fountain. The style is Late English, with mullions and transoms, the upper lights being filled with small panes and lead quarries. No details are shown. "Walter" is a sensibly-designed elevation; the long side is broken by a pedimented projection, with entrance in centre, and the details are carried out in the spirit of Queen Anne. A flower border surrounds the interior. "Bonus Hominus" is another suitable design, and is made to project about half the width, the other half being recessed. There is a tiled centre space with side borders. The entrance projects, and is hipped; and the lights over the transom are filled with small panes, ornamentally arranged. "En Avant" is appropriate; the lights are designed to open by lever apparatus, and the top lights are lead-glazed in colours. The rafters are trussed; diaper panels are shown below the sills. "Quiet and Simple" is a Queen Anne elevation, with three gables intersecting the main lean-to roof. "Pupil J." sends a rather *outré* design, having a span roof with lean-to projection all round, and a clerestory arrangement of lights to open. The entrance forms a transept. We do not admire the arched lights; no section is shown of the construction. "Vignette" shows a top lantern, "Spes" a gabled side, "Con" in circle has taken particular pains to show a curvilinear-shaped bed of flowers and borders, and "Desire" is remarkable for a flat roof curved at the springing, and the whole filled in with narrow lights. A few of the designs are copies.

PROPOSED IMPROVEMENTS AT BILLINGSGATE MARKET.

WE have before us a pamphlet, written by Captain W. E. Heath, which sets forth a novel and ingenious scheme for the retention and enlargement of the present Billingsgate Market. As a commission is now employed inquiring into the best means of making the market adequate to the wants of the Metropolis and to take evidence thereon, Captain Heath's suggestions will be read with the attention the subject deserves. The author shows conclusively, we think, that there is no other better locality than the present site of the market available for a new one. Neither on the Middlesex nor on the Surrey side is there a position that can compare with it. The Surrey shore is cut off by bridges from the termini of the chief fish-bearing railways. To shift the site eastwards or westwards, equal difficulty would be experienced, Upper Thames-street to the west is narrow and crowded, and the steep gradients of the narrow side streets would be objectionable, while beyond Blackfriars the Embankment forbids the utilisation of any site. Eastwards, there is no space, as the Custom House Quay, the Tower of London, and the succession of wharves and docks prevent the acquirement of a site; and the author points to the difficulties that would beset the attempt to convert St. Katherine Docks into an area suitable for the purpose, surrounded as it is by little narrow streets and distant from the principal railway-stations. It is much easier to build a market than to establish one, as Captain Heath observes, and he cites with much force the Columbia Market as an instance of the folly of building one anywhere. A market, moreover, is the growth of years and circumstances, as fishermen, salesmen, and fishmonger connect themselves to the old site, and many interests would be completely destroyed by an attempt to remove Billingsgate Market from the site it has so long enjoyed.

Let us see how the author proposes to carry out his scheme, which is illustrated by two plans. He proposes to "remove the whole of the upper part of the present market as low down as the top of the entablature that rests on the internal columns, and construct on iron girders a flooring or watertight roadway of wood or asphalt over the whole area pierced at proper intervals with staircases and wells for hydraulic lifts for porters carrying fish or for passengers, while lifts should travel up and down at stated intervals of a few minutes, while the business lasted." The present roof would be thus taken off and the side walls pulled down to the necessary level, a new asphalted floor made over the entire area with openings for lifts and hoists, and the roof would then be replaced on columns or piers leaving the sides open to the air. From this platform or floor-level a viaduct would be thrown across Lower Thames-street at the western end of the market giving a headway of 30ft. and a roadway 45ft. wide; the roadway thence it is proposed to carry by an easy gradient of about 2 in 100 to near the top of Love-lane on columns or arches. The roadway thus formed would connect the market with Eastcheap at its west part, at which point are three channels for relief, north, west and east. The line of road shown on plan is not quite straight, but has a slight turn in the direction, and the positions of St. Mary's Church and the ward school in Love-lane will necessitate a rather unpleasant curvature in the centre to clear them. The removal of the school would enable a straight or pleasingly curved line to be formed at probably little increased cost, which would obviate the crippled appearance at this point. We make this remark only as an esthetic suggestion. In its main features the roadway would be a decided relief to the market. The author proposes that the purchase of property required to construct this high-level road may be met by a toll on vehicles using it, though the new frontages made would largely recon the cost of the roadway. Lower Thames-street would still be available for traffic, and the new approach would vastly relieve that now very much congested thoroughfare. The plan shows width of new roadway for four lines of traffic, two stationary and two moving, besides footways for porters and others. The standings on the stationary lines may, it is suggested, be numbered so as to be readily found by the porters when carrying their loads to the fishmongers' carts below. The new platform or floor of market, sheltered as it

would be by the roof, could then be used for the railway vans, and by a gallery constructed over the jetty on the river front, fish could be hoisted direct from the boats. The plan given of this platform shows standing room for 50 railway vans with two horses round the area, while two stairs, two load lifts, and a passenger and porter lift are indicated in the centre.

On the whole, Captain Heath's proposal is worth the attention of the special committee of the Corporation which is now sitting; the advantages pointed out by the author are not exaggerated, as any scheme which retains the present market where it is cannot fail to be the most economical one, and to meet the requirements of the fish trade. Lower Thames-street would be greatly relieved, and be left for the other traffic, and the time saved in loading and unloading would ultimately tell in favour of the consumer.

THE IMPROVEMENT OF ARTISANS' DWELLINGS.

LAST week a conference of gentlemen interested in the improvement of artisans' dwellings was held in the Guildhall at York. There was an influential attendance. In opening the meeting the Chairman (the Lord Mayor) said one of the more definite objects of the meeting was to arrive at a conclusion as to whether it was necessary, in order to improve artisans' dwellings, that anything should be done in the way of the formation of a company or otherwise. Mr. W. H. Empson said the only way to provide proper buildings would be by building in the block system, or that which Sir Sidney Waterlow had adopted in London. He (Mr. Empson) thought there could be no difficulty in building on either of these plans at York, and making it a success. Having given information on Sir Sidney Waterlow's system, which, he said, was a paying concern, Mr. Empson gave statistics as to cost.—Mr. Demaine also described the buildings in London, and gave estimates of the cost of erection, and the rent required.—Mr. Ernest thought that increased accommodation was required in York, and had no doubt speculation would be successful.—Dr. North referred to the question of public health, which, he said, was the main question. He said that beyond certain limits, exactly in proportion as the population per square mile was increased, so the rate of mortality increased. With regard to the building of blocks, though it might have to be submitted to of necessity, if they piled up houses one upon another, those persons living in the top rooms would have the disadvantage of living and breathing the atmosphere of those below. Having referred to the necessity of adequate ventilation behind and in front of houses, the speaker said that another great question was that of morality, that was as to whether it was for the good of morals whether people should live in huge barracks in which persons of all sexes should be congregated as though in common lodging-houses. In his opinion these sort of houses were an unmitigated nuisance, centres of social injury, and tended greatly to deteriorate public morals. At the present moment he did not think there was any stern necessity for blocks in York.—The Rev. T. D. T. Speck agreed with the previous speaker as to the disadvantage experienced by persons living in top stories of high buildings.—Mr. Butler agreed with the opinions of Dr. North, relating his experience with reference to the system of blocks. He thought that they tended more to deteriorate the physical and moral condition of the people occupying them than otherwise.—The discussion was continued by Mr. Rymer and the Rev. G. M. Argles, the latter of whom considered that more small cottages at about the rent of £10 were required. The sheriff (Mr. R. Thompson) said that the moral and physical question was of considerable importance, and wanted well discussing first. After further discussion, the meeting was adjourned *sine die*.

A new Welsh Calvinistic Methodist Chapel has been erected at Newborough, Anglesey. The chapel, which will seat 650 people, has been built on the foundations of the old structure, with the addition of a porch, at a cost of about £1,400. Mr. Elias Jones, Dwyran, was the contractor, and Mr. Richard Davies, Bangor, the architect.

OUR LITHOGRAPHIC ILLUSTRATIONS.

BEVERLEY MINSTER.

BEVERLEY Minster, originally a monastery, was founded by St. John, of Beverley, about the year 700, and destroyed by the Danes in 866. It appears to have been re-founded and made collegiate, about the year 928, by King Athelstan, who endowed it with large privileges. By the favour and bounty of succeeding kings, and of the Archbishops of York, who claimed the immediate patronage, it continued to flourish for many years. There are four transepts, the two choir-transepts built in the year 1188, belonging to the earliest part of the church, and resembling that of Salisbury. At the time of dissolution, 1st Edward VI., it consisted of a provost, eight prebendaries, a chancellor, precentor, seven rectors choral, nine vicars choral, with many chantry priests, clerks, choristers, officers, and servants; the first provost being Thomas, of Dyeaux, afterwards Archbishop of York in 1592, and Thomas à Beckett in 1150. The west end of the minster is adorned with two lofty towers 160ft. in height. The total length from east to west is 34ft.; breadth, 61ft.; length of great transepts, 167ft.; height of vaulting, 67ft. In the choir stands the Mid-stel, a chair of one entire stone, said to have been removed from Scotland, in which those who sought sanctuary in their minster were seated at their admission. St. John, of Beverley, was born at Herpham-on-the-Wolds, and was the first M.A., Oxon. His bones are stated to have been found, in digging in Beverley Minster, Sept. 13th, 1661.

SHREWSBURY SCHOOL—NEW CHAPEL.

THE grammar-school at Shrewsbury will shortly be removed from its present quarters to a new site on the other side of the town, overlooking the Severn, opposite the quarry. Here it will occupy an old building, which was originally designed in the last century for a foundling hospital, but is now being altered and adapted to its new purpose. A head-master's house, and two under-masters' houses, the latter by Mr. William White, F.R.S.A., are also in process of erection on the same site, which affords ample space besides for play-ground, cricket-field, and other necessary adjuncts of a large school. The buildings are all of red brick, but the governing body have decided that the chapel, which is not yet begun, shall be of stone, the cost being limited to £7,000. Of this sum, £3,000 has been raised for a memorial to Dr. Kennedy, the late distinguished head-master. It was stipulated that the memorial should form some distinct and definite portion of the building, a proviso with

which it would have been difficult in a college chapel to comply. It was decided, however, to seat the building as a church, and a chancel, which thus became a necessary feature, naturally met the requirement. The building has been designed to bring each portion within the stipulated limits of cost, and will, when complete, accommodate 500 boys besides the masters, their families, and a limited number of visitors. The old screen and pulpit, and such other fittings as can be re-used, will be retained in the new chapel. The chapel will stand on the west side of the school-building.

NEW CHURCH, ROTHERHAM.

PROPOSED to be built at Moorgate, of local red brick and red stone. E. Francis Clarke, architect, 7, Westminster-chambers, London, S.W.

NEW TOWN HALL, GRAHAMSTOWN (CAPE COLONY).

THE New Town Hall at Grahamstown, Cape Colony, which we illustrate in our present number, has nearly reached completion, the contract time—two-and-a-half years—expiring in September next. It is one of the most extensive buildings in the country, and, being of stone, is an improvement on the brick and plaster which till of late was too generally adopted throughout the colony for buildings of all descriptions. As our illustration gives a ground-plan of the building, its extensive accommodation will be seen, and a second story extending over the front portion affords, in addition to this, four large museum and two committee-rooms, and at the back, under the anterooms of assembly-hall, there is a roomy basement for taxidermist, store, and other purposes. The design is by Mr. Sydney Stent, F.R.I.B.A., Assoc.M.Inst.C.E., of the Cape Public Works Department, and was the successful one in a general competition advertised by the municipality some four years since. A general ground-plan formed one of the conditions of the competition, and another was that tenders should be obtained within the limit of cost given. The conditions were (which is not usual on the part of municipal authorities) adhered to: it was also a *sine qua non* that the tower, which is a jubilee memorial, should stand out as a distinct part of the building, so that architectural treatment became somewhat restricted. The foundation-stone was laid by Sir Bartle Frere, Bart., on the occasion of his first visit to Grahamstown as governor of the colony. A special feature in the carrying out of the design is the use of moulded cement concrete for all dressed work except the plinth-course, which is cut stone. The mixture for this is 4 of broken stone, 2 of sand, and 1 of cement: it is cast in blocks the sizes that would have been used had cut stone been adopted, and was allowed to stand under cover not less than a month before use. The blocks are built and bedded in the work, and afterwards pointed, just as stone would be, in cement mortar. Had this been done in coal-ash mortar, a more distinct joint would have been obtained, and the work would have looked better, perhaps. The cost of cut stone in Grahamstown precluded its use, and but for this successful substitute, no dressed or ornamental work could have been introduced into the design. As it is, the effect of stone has been obtained at a small cost, and casual observers do not detect the difference. A little ingenuity and skill is required in constructing the moulds for some of the more intricate castings, but the actual moulding of the blocks themselves is readily acquired by any careful and good workman in a week or so. The durability of this concrete is no doubt greater than that of stone, and its only drawback is the coldness and monotony of its colour or tint; but this, where it is used only partially in a building, as in the case before us, and where it thus has the relief of the stonework, is hardly noticeable. In using concrete for the same purpose again, the architect would adopt different proportions, and would admit as much as $\frac{3}{4}$ of sand, instead of 2, to the 1 of stone and 1 of cement. The ventilation of the building will be very complete, being accomplished by vertical tubes, a special contrivance of window-sashes, and cornice outlet spaces in all the rooms. The assembly-hall, which is 82ft. by 50ft., will seat about 600 persons. A local builder, Mr. J. W. Abbott, is the contractor, and he has carried out his work, under most adverse circumstances, most satisfactorily. The contract price of the whole was £14,800.

BODNANT, NORTH WALES.

THIS building, which has been erected for H. D. Pochin, Esq., is situated in a most picturesque part of the Conway Valley, at an elevation of about 200ft. above the river, and commanding magnificent views of the Snowdon range. It is built on the site of an old house, which, however, possessed nothing of interest, and of which some minor portions have been worked into the interior of the new house. The walls are hollow throughout, and are constructed of a grey Chert stone quarried on the estate, and the whole of the moulded and dressed stonework is executed in Talaere stone. The roofs are covered with Welsh slates, and a certain relief of colour is obtained by the use of the half-timbered work in the upper portion. The surrounding country being very much broken up and richly wooded necessitated considerable play of outline in the general design, and especially in the roofs, to make the building harmonise with its surroundings. The work was executed by Messrs. Lucas Brothers, the architect being Mr. W. J. Green, of 8, Delahay-street, Westminster.

COTTAGE AT WEST STRATTON.

THIS is the first of a group of cottages to be built in the village of West Stratton, the seat of the Earl of Northbrook. The external walls are of unsquared flints, with the mortar-joints brushed over to give a good texture; the quoins and jambs and heads of windows are in red brick, pointed in mortar. The half-timber work is all of English oak. The roof is covered with red Broseley tiling. The work has been faithfully and ably done by Mr. Mussellwhite, of Basingstoke, from the designs of Mr. Ernest Newton, of 14, Hart-street, Bloomsbury-square.

ARCHÆOLOGICAL.

SUPPOSED TWELFTH-CENTURY REMAINS AT TANKERSLEY.—Last week the workmen engaged in carrying out the scheme for enlarging Tankersley parish-church made several interesting discoveries. The scheme of enlargement embraces the erection of a new porch in place of the old one, which, according to an inscription in the wall, was built in 1726. In pulling down the walls of the old porch the workmen have found about a score of different sized stones, and of various shapes, on which some ancient emblems appear, consisting chiefly of the sign of the cross. On one stone, 1ft. long, are a cross and a sword side by side. Several stones have round heads, and the figures on them are circles within which Greek and Latin crosses are inscribed. The cross and the sword are also on other smaller stones. In addition to the cross one stone has a rude outline of a number of steps, and on another stone is a cross and a very good sketch of a pair of shears, which no doubt were inscribed to indicate the trade of the person interred beneath the stone. The whole of the stones have been examined by Mr. Hadfield, architect, of Sheffield, who considers that they relate to the twelfth century. The sign of the shears would indicate that the iron trade was carried on in the locality of Tankersley 600 years ago. In clearing away the earth near the porch on the east side, a large stone coffin, six feet long, containing human bones, was found. The coffin has a place at the top for the head, and then widens to admit the shoulders. It gradually diminishes in width to the feet. On the top of the porch was found a large flat stone, on which were sketches of the cross and a scimitar.—*Sheffield Independent*.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

ESSEX ARCHÆOLOGICAL SOCIETY.—The annual general meeting of this society was held at Chipping Ongar yesterday. The chair was taken at the Trust School at 12 o'clock. At two o'clock the meeting visited Ongar Church and Castle, and proceeded from thence, at a quarter to three, to the ancient and interesting timber church at Greenstead. Afterwards, by the invitation of Captain Budworth, the reservoir of a holy well at Greenstead Hall was inspected.

At a special meeting of the Dover Town-council held last week, the tender of Mr. H. Stiff, amounting to £15,982, for the new municipal buildings, was accepted.

ANCIENT WOOD AND IRONWORK IN CAMBRIDGE.*

WE have received Part II. of a work under the above title, by Mr. W. B. Redfern, Member of the Cambridge Antiquarian Society, assisted by the Rev. D. J. Stewart, M.A., and John Willis Clark, M.A., who have aided the author in writing the letterpress. As the latter gentlemen are authors of archaeological works, we may take it for granted that accuracy of drawing and description will be maintained. The present part contains three lithographic plates. The first of these represents a beautiful wood carved chimney-piece of the 16th century in a small house, No. 3, Sussums-yard, Bridge-street, belonging to St. John's College. It has the date of its construction on a small shield in the centre of mantelshelf. Only two compartments are shown, in order to give the detail large. Four groups of coupled Corinthian columns, raised on pedestals, divide the space into three panels. These panels are inlaid with coloured woods, and are all three alike. The subject represented is an Oriental temple, with a lake in front, having swans swimming. We are sorry the details of the mouldings are not given. The whole is surmounted by a deep entablature with lions' heads in the frieze over the coupled columns, and with a fluted enrichment in the longer portions of the frieze. Round each of the chief panels is an enriched echinus. The next plate is even more interesting. It shows the ancient bookcases in Trinity Hall Library, which, together with that at Merton College, Oxford, are the only two libraries in England in which the ancient arrangements are preserved. The Trinity Hall Library is a long and narrow room, 65ft. long by 20ft. wide. It has eight windows in each wall (two-lighted), and a high waggon-shaped roof. The bookcases or "stalls" are placed at right angles to the walls, between each pair of windows, with the seats directly in front of the windows, and at a certain distance from the cases. These bookcases have sloped tops or desks, below which is a shelf for books. Under this a desk, which could be pulled out if required, was placed. The details are particularly interesting, as they show the manner in which the books were chained to the desk. One end of the chain was fixed to the left-hand cover of the book, and the other end had a ring which passed over a long iron bar beneath the sloping desk, which was secured at the end by an ornamental iron lock at the end of the case. The bar shows a long clasp, which is fastened to the lock front by two keys. Plate VI. illustrates a carved oak arm-chair, date about 1630, now in the possession of Mr. A. J. Gray, Hills-road. A front and side view of the chair with plan are given. The seat is square-ended, slightly tapered behind, and the side framed rails are enriched by large half-circles with a bold leaf-pattern. The back has a square top rail which crosses the upright framing. These are richly carved with scroll-work and guilloche ornaments, while the back has a circular guilloche border surrounding a panel inlaid with a geometrical pattern in black and yellow wood, the design of which is essentially Oriental in character. The front legs are boldly carved and the framing is massive. These illustrations are drawn to a scale of 2in. to 1ft. The drawings are produced by the Anastatic process, the merit of which is that the touch of the original is retained. If the succeeding parts equal this one, the subscribers will have no cause to complain.

THE RIGHT TO LATERAL SUPPORT.

COMMENTING on the recent case of *Angus v. Dalton*, which we reviewed at length on page 727, last vol., *Engineering* remarks that "It is somewhat surprising, considering the subtle and highly technical grounds on which the arguments and judgment proceeded, that the defendants did not raise what seems to us to be the true nature of the right claimed. It was admitted that the pillar of clay which was left by the excavators was, in the state in which it was left, amply sufficient for the support of the stack, and that the accident arose from the drying action of the air upon the clay when ex-

posed. The right claimed, therefore, in this case resolved itself into a right to have the supporting clay covered up by the defendant's soil, so that its moisture, and consequently its supporting qualities, might be preserved. We do not think that plaintiffs could have claimed a right to have the protection of defendants' soil to keep their clay wet, any more than they could have claimed a right to have the protection of the defendants' wall to keep their building dry. The point, however, was not raised, and the decision proceeded as if the right to support alone were in question. According to the law as it now stands declared, a building erected upon the edge of the proprietor's land has, after twenty years, a right to the support of the adjoining soil, and this, however shallow, may be the foundations. Thus, though the foundations be merely 'scratched in,' as is the practice with speculative builders of the present day, after the building has stood twenty years the proprietor of the adjoining land will be debarred from excavating it, even to a small extent, except at his own risk. The only way in which he can effectually prevent the acquisition of the right is by digging a hole in his land during the twenty years, and actually letting down his neighbour's building. On the other hand, the building may have its foundations laid deep and solid, yet, until the lapse of twenty years, the proprietor has no security that it may not be brought about his ears, except in the forbearance of his neighbour. If his neighbour, as sometimes happens, put up next to him a heavy building, which by its weight disturbs his foundations and cracks his house or lets it down, he has a right to compensation; but if, within twenty years, his neighbour maliciously excavates and produces the same effect, he has no such right. But for the forbearance of which we have spoken, a state of things such as this would have long ago become intolerable in the metropolis and other large towns. As it is, this forbearance cannot always be relied on, and now that the present state of the law is definitely determined, the question arises whether or not it should not be amended by the action of the Legislature. The course which may be proposed is that by laying the foundations at a certain depth, varying perhaps according to the neighbourhood and the weight of the building, an immediate right to the support of the adjoining land should be gained. Another plan which suggests itself is that a person proposing to build along the edge of his land should give the adjoining proprietor notice of the nature of the proposed building, and the proposed depth of foundations. If no objection be made the work could proceed, and the right be immediately acquired. If objection be taken and the parties fail to come to terms, the matter should then be submitted to the district surveyor or to an arbitrator agreed on by the parties, who should award upon the matter and state how much, if any, compensation should be paid to the adjoining proprietor in respect of the diminished value of his land by reason of the depth to which he may excavate upon it being limited. The compensation being paid by the building erected in accordance with the award, the right would then be acquired as before. The rights of the parties would thus be at once finally ascertained and determined, without the lapse of twenty years and the intermediate uncertainty. Some such solution of the difficulty seems to be called for, whenever an overworked Legislature can find time to turn its attention to the subject."

BUILDING A HOUSE ON A SAND-HILL.*

AS I am not aware that it has ever before been attempted in the United States to build a house on the very top of a lofty sand-hill, exposed to all winds and weather, while simply depending upon, or rather by simply making the loose sand the agent to keep it firmly secured in its seat, I think a few words upon the construction of a single station, which I have just finished for the Maritime Exchange of this city, on top of the highest sand-hill at Cape Henlopen, may be of interest to some.

The signal station mentioned will serve to report the arrival at and departure from the Breakwater of all passing vessels, to the

Philadelphia Maritime Exchange, by means of the Western Union Telegraph lines which connect it with this city.

In the first place, it was necessary that the observer stationed in the building should have a clear and unobstructed view of the seaward horizon from south to north, that is seaward of the coast line. To obtain this it was necessary to erect the building on top of a hill, which rises some 80 feet above the level of the sea. But the building thus necessarily becomes exposed to every gale that sweeps that part of our coast, while it is absolutely required that it shall stand firmly planted in such a way that even a hurricane shall not shake it or make it tremble, as that would affect the sight of the telescope in the observatory.

The usual mode of securing is by building a foundation of screw piles or of heavy timbers sunk into the sand; the latter mode, however, has this disadvantage, that if the wind shifts the sand away from around the foundation, it becomes undermined and its effect is thus destroyed.

In order to be independent of all this, I designed what I consider a cheap and, at the same time, an effective anchorage for the building in the following manner. The building is of wood entirely; it has a cellar, above which are two rooms, one above the other, and the whole surmounted by the observatory proper. First, the ground-sill is a square of 20 feet, made of yellow-pine sticks, mortised together and pinned with stout trunnels. The sill of the observatory is made likewise of heavy timbers, 12 feet long. The two sills are joined together by four stout yellow-pine corner-posts, which in turn are mortised into both sills. The posts are 26 feet in length. Five feet above the lower sill is the sill which supports the floor of the first room, ten feet above this is the sill which supports the upper room. Both these sills again are mortised into the corner-posts. This structure is sheathed outside with German siding, inside with rough boards covered with felt, and again by tongued and grooved yellow-pine boards. The observatory proper, octagonal in shape, is securely mortised into the top sill and is covered with a corrugated-iron roof, conical in shape. The cellar is floored with 3-inch wood, and boarded all around on the inside of the posts.

I first dug a pit in the sand, about 6 feet deep and fully 20 feet wide on the bottom. I then laid the ground or cellar sill on this bottom, and built the structure: thus the whole depth of the cellar is sunk below the top of the hill, or the level of the sand. I then filled the cellar up solid with sand, and packed it solid all around the outside also; consequently the building is anchored in its place by the load in the cellar, some 100 tons in weight.

I carried three heavy joists (part of the joists which carry the first floor) through on one side of the building, and on these the kitchen was built, so that this is also independent of the position of the sand under it. Since the construction of the station we have had some very severe blows, yet there is no more tremble in the building than if built of stone on a rock.

A few feet from the building stands a signal post or mast 100 feet high, which carries a 5-foot ball of rattan covered with canvas; the ball is made to slide on the mast, and is used to answer signals from vessels by raising and dropping it. As it would, in my opinion, be a rather dangerous thing to simply place the mast in the sand,—no matter how deep,—I sank a well into the sand-hill.

This well is made of pine, 20 feet deep and 8 feet square. The mast is placed in the centre of the well and is braced, from the corners of the pine box, by some 20 stout braces, and the well afterwards filled and tightly packed with sand inside and outside, so that, like the house, to blow it over would necessitate moving of a tremendous weight of sand with it.

TIMBER FROM STRAW.

WE referred some months ago to the invention of a process for producing solid masses or blocks of any form and size from straw, which had been patented by a Western inventor. The *Northwestern Lumberman*, of recent date, reports the receipt of a sample of such lumber, made from straw, from the inventor, Mr. S. W. Hamilton, of Lawrence, Kansas, U.S.A. The inventor of this product claims that he can manufacture timber in any desired length, from

* Ancient Wood and Ironwork in Cambridge. By W. B. REDFERN, assisted by Rev. D. J. STEWART, M.A., and JOHN WILLIS CLARK, M.A. Published by W. R. Spalding, Cambridge. London: W. Kent and Co.

*A paper by Mr. J. J. DE KINDE read before the Engineers' Club of Philadelphia.

12ft. upward, and to 32in. wide, at a cost competing with the better or finishing grades of pine. Our contemporary says of the sample sent to it, that it will hold a nail as well as wood, that it is equally susceptible to a high painting finish, and can be polished to as high a degree as is desirable. It is made waterproof, and there seems no reason why it should not be so durable, or more so, than pine, or even oak, while its adaptability is evidently as great for roofing purposes as for the fine work of a dwelling.

The new material appears to be capable of being worked under the plane and other tools of the carpenter, and has the special advantage of being free from knots and not liable to shrinking, swelling, warping, and splitting. The material, judged from the sample, is reported to resemble hard wood in appearance, being about as dark as oak, but more dense in texture, and with a specific gravity one-fifth greater than thoroughly seasoned black walnut. Its tensile strength is reported to be about double that of wood of the same thickness.

ART ON THE STAGE.

SCENE-PAINTING is an art by itself. There is no other branch of painting just like it, either in the variety of subjects embraced or in the methods employed. The thorough scenic artist must be equally at home in landscape or marine work, architectural or fresco. He is not permitted to cultivate any particular branch of his art, nor any favourite style. He must be able to produce, at any time, the wild mountainous passes of Switzerland or the flat meadows of Holland; the green lanes of home-like England, or the winding valleys of romantic Spain. In his architectural work he cannot devote himself to the Gothic or the Romanesque, but must be equally master of the Moorish, the Greek, and the Oriental. He may to-day be called upon to paint the Temple of Minerva, and to-morrow the Mosque of Omar; this week the Windsor Hotel, and next week the Palace of Versailles. His art knows no boundaries, and his scope is confined by no limits. The universe must be at his command, and things unseen must live in his imagination. The methods by which he works and many of the materials he employs are altogether different from those employed by the ordinary oil or water-colour painter. They approach more nearly to those of the latter, yet even here certain qualities of the colours used by the scene-painter constitute a sharp dividing line.

In the first place, the ordinary water-colour painter works upon paper. The scene-painter uses canvas. He first makes a pasteboard model of his scene and gives it to the stage-carpenter, who builds the frame-work and pastes the canvas upon it. It is then ready for the "paint frame." This is a huge wooden affair, hung upon ropes, with counter-weights attached. It is usually placed against the wall at the back or side of the stage, and has a windlass attached by which it may be hoisted and lowered. The artist works upon a bridge built in front of this frame and at its top when the bottom is touching the stage. By hoisting or lowering the paint frame he is enabled to reach any part of his scene. He is provided with plenty of brushes, ranging from a heavy 2lb. brush, such as is used by house-painters, to a small sharp one for drawing fine lines. In addition to these he has several whitewash brushes for laying in flat washes and skies.

His colours are kept in buckets, tin cans, and other ware vessels. His palette is a long table with partitioned compartments on the top to hold small quantities of colour. Give him now his palette-knife, his rule, plenty of twine and sticks of charcoal, and he is ready to go to work. His first duty is to "prime" his scene. This is done with a plain coat of white. These colours and all others used by him are mixed with "sizing," which is simply a weak solution of glue. Working with colours mixed in this way is called painting in distemper, and has certain advantages which will be spoken of further on. The priming coat is laid on with a heavy whitewash brush, care being taken to drive the colour well into the canvas. Sometimes heavy unbleached muslin is used; but the usual material is duck.

After the canvas is primed and dry, the artist is ready to draw. Most scenic painters do their

first drawing in a very sketchy manner. After the charcoal outline is finished, it is gone over carefully with an ink prepared especially for the purpose, and not used in any other branch of art. In architectural drawing this part of the work is necessarily done with the greatest care, as regularity of outline and accuracy of detail are absolutely necessary. A scene-painter's outline for a landscape, however, looks very much like the off-hand outline productions hastily done by an old hand at sketching from nature. The scene-painter must be a master of perspective; for street scenes and palace corridors are frequently produced by him. The method of drawing in perspective on a large scale is curious, though substantially the same as that usually employed. The artist selects his "vanishing point," usually outside of his scene, and attaches to it by a pin a long piece of twine. Beginning at the top of the scene he marks off, in the foreground, the distances between his lines. He then blackens the twine with charcoal, and, laying the loose end on his first mark, draws it tight and snaps it upon the scene, making a line in the same manner as a carpenter does upon a long board. These lines are afterward gone over with ink and ruler. In this way he is able to produce a perfect perspective. Exterior scenes, in which a castle or other large building appears, often have the perspective increased in effect by continuing a wall or rampart down the stage upon a separate piece set exactly in the line of perspective.

SECRETS OF THE SCENE-PAINTER.

The next step is the laying in of the ground-work. The sky is, of course, the first point. This is done with whitewash brushes, the painter being absolutely free from all restraint in his method of putting on the colour. The principal point is to get it on quickly. And here the great advantages of painting in distemper become thoroughly plain. These advantages are two in number: the first is, that the colour dries very quickly, thus affording the artist a high rate of speed in working; secondly, all the colours retain, when dry, precisely the same tint as they had before being mixed. The addition of the sizing makes each colour several shades darker than it is when simply in the powdered state. The knowledge of this fact and thorough understanding of the effect the tints will produce after drying is one of the great secrets of the art. Oil-painters of high standing have been known to try the distemper method with utterly disastrous results. Colours mixed with oil always darken several shades and remain dark. Colours mixed with sizing always dry out to their original shade.

Different painters have different methods, and there is as much variety in the school of scene-painting as in other branches of art. The German, French, and American artists use opaque washes, or, as it is usually expressed, work in "body colour." The English school, in which the greatest advances have been made, use thin glazes. This in scene painting is the quickest and most effective. Morgan, Munton, Fox, and Voegtlin are among the leading representatives of this school in America, and their method is gradually spreading among the artists of that country. Its rapidity may be judged from the fact that one of these artists lately painted a scene measuring twenty by thirty feet in less than four hours.

One of the greatest differences in scene-painting from ordinary water-colour painting is that, while the colours of the latter are transparent, those of the former are opaque. For instance, the water-colour painter can lay in a wash of yellow ochre, and, by covering it when dry, with a light coat of madder lake, can transform it to a bright orange. In distemper, however, the coat of madder lake would not allow the yellow to show but would completely hide it, and the tint presented would be pure pink. From this fact results a total difference in the painting of foliage. The water-colour painter lays in his light tints first and puts in his shades afterwards. The scene-painter may do this or not as he pleases. He may put his light tints over his dark ones and they will not lose any of their brilliancy. The advantage of this in regard to speed may be easily seen. If the water-colour painter wishes to put a high light in the middle of a shadow, he must first erase with a sharp knife a portion of his dark tint, or else put on a heavy spot of Chinese

white. Over the spot thus erased or whitened he puts the required tint. The distemper painter is relieved of this roundabout process, for he simply dots in his light colour wherever he needs it over the darker shade, and it shows with perfect brilliancy. Again, in painting skies the scene-painter works by a method of his own, not unlike that adopted by oil-painters. The water-colour painter must leave all the broad light of his sky when putting in the main colour, and is obliged to work with his tints wet. The scene-painter may lay in the entire sky with blue, and paint his light yellowish clouds over it afterward. If the ordinary water-colour painter were to do this, his clouds would be green. Some scene-painters, however, work their entire skies wet. The effect of a sky painted thus is always very fine, but only an artist thoroughly conversant with the values of his several pigments can do this. For the colours, it will be remembered, present a very different appearance when wet from that which they have when dry.

Scene-painting has become so important an art that one large firm in New York makes a great speciality of imported materials. There is a long list of colours and other things used exclusively in scenic art, and improvements are being constantly made. Formerly scene-painters were obliged to grind their own colours, but these are now prepared in "pulp"—that is, ground in water. Among the colours used almost exclusively by scenic artists are English Paris white, zinc white, silver white, drop black, Frankfort black, Turkey umbers, Italian sienas, Cologne earth, Dutch pink, Schweinfurter green, Newwider green, ultramarine green, Bremen blue, azure blue, Persian scarlet, Turkey red, Tuscan red, Solferino, Magenta, Munich lake, Florentine lake, Vienna lake, and blue lake. Some of these colours are also used by fresco painters.

Those which are never used except by scenic artists are celestial blue, golden ochres, green lakes, Milori greens, French green and yellow lakes. The colours specially imported for scene-painters are carnation, royal purples, green lakes, and the English chromes. Indigo is used in very large quantities by scenic artists, but it is used very moderately by water-colour artists. It adds considerably to the expense of getting up scenery.

OTHER MATERIALS USED.

The scene-painter, however, is not confined to colours in producing his effects. There is a number of other materials of great importance in scene-painting. The gorgeous dashes of blue, crimson, yellow, and purple that make the resplendent fairy grotto are not alone sufficient. The glitter that is seen on the many-coloured stalagmites and stalactites is produced by ordinary gold and silver leaf. Sometimes it becomes necessary to produce upon the scene a smooth, glittering surface which shall be coloured. This is produced by foil papers. They are made of paper with a polished metallic surface, and are very effective in fairy scenes. What are known as bronze powders are made of all shades. They are metallic powders of gold, silver, bronze, steel, blue, red, purple, and other shades. A brush full of glue is drawn across the required surface, and the bronze is spread over it. The consequent appearance is that of a rough metallic surface similar to that frosted silver.

In some scenes it is necessary to represent precious stones. The jewels in the walls of some Eastern despot's palace cannot be imitated by paint with a sufficient degree of realism to stand the glare of gas and calcium light. Hence, theatrical art resorts to what are called "logies." These are made of zinc, in the shape of a large jewel, and are set in the canvas. They are made in all colours; and thus, by a very cheap and easy process, the barbaric splendour of Persia or of Turkey may be reproduced in all its original opulence. Sometimes it becomes necessary to represent that changing sheen that is visible upon highly-polished metals when exposed to the rays of the sun. This is done by means of coloured lacquers. The surface of the metal is painted, and a wash of these lacquers, blending from one tint into another, is put over it. The light reflected from these different coloured washes produces the desired effect, and gives a highly realistic representation of a surface of metal.

An ice scene is never complete without some-

thing to produce glitter and sparkle. This effect is produced by "frostings" of crushed glass, which are made to adhere to the canvas in the same manner as the bronze powders. The elaborate ornamental work in interior scenes is always done by means of stencils cut in paste-board. There are books published on fresco painting which give large numbers of beautiful designs for panels, ceilings, mouldings, and other ornamental work. Every scene-painter has a collection of these works. The ingenious artist, however, is constantly combining the different designs, and often invents new ones. He is thus enabled to present to the public an ever-changing variety.

The last thing that the scene-painter does before the production of a new play is to have his scenes set upon the stage at night in order that he can arrange the lighting of them. The "gas-man" of a theatre is the artist's mainstay. It lies in his power to ruin the finest scene that was ever painted. Ground lights turned too high upon a moonlight scene, calciums with glass not properly tinted, or the shadow of a straight edged border-drop thrown across a delicate sky—all these things are ruin to the artist's most careful work. The proper lighting of a scene is, therefore, a matter that requires the most careful study. The artist sits in the centre of the auditorium and minutely observes every nook and corner of his scene under the glare of gas. Here a light is turned up and there one is lowered until the proper effect is secured. The gas-man takes careful note of his directions, and the stage-manager oversees everything. Long after the audience has left the theatre on the night before the production of a new play, the stage-hands, the artist, and the stage manager are at work, and the public sees only the charming result of their labours when the curtain rises on the next night. —*New York Tribune*.

WATER SUPPLY AND SANITARY MATTERS.

BURGESS-HILL, SUSSEX.—The local board of Burgess-hill have appointed Messrs. Bailey Denton and Son their engineers, to carry out a scheme of sewerage and sewage disposal for their district.

WATFORD, HERTS.—The urban authority of the above town have called in Messrs. Bailey Denton and Co. to modify the present arrangements on their sewage farm by the introduction of intermittent filtration in combination with wide irrigation. Several of the neighbouring sanitary authorities might follow the example with advantage. At Harrow, Willesden, and other places, the sewage difficulty is to the front just now, and must sooner or later be settled somehow.

EAST DEREHAM.—The local board of East Dereham, Norfolk, received last week a detailed report from the surveyor, Mr. W. H. Nankivell, as to the progress of the new scheme of water supply. He stated that the section of laying water mains from the works to the market place had been completed, and the remainder of the pipes were being laid by the contractor, Mr. Hubbard. The fittings had all been delivered by the Glendfield Company, Kilmarnock, and the water-works tower had been built. The tender of Mr. Alfred Dodman, of King's Lynn, was accepted for the supply of engine, boiler, and pump at £494 19s. A scheme of sewerage is also in progress from Mr. Nankivell's plans.

ANNAN.—New waterworks at Annan were opened last Friday. The waterworks were commenced nine months ago, the contractors being Messrs. Brehner and Fleming, contractors, Edinburgh. The reservoir is situated seven miles from Annan, on the Middlebie Burn, in the parish of Middlebie. It covers 16 acres, and is estimated to hold 27,000,000 gallons of water. The filter-bed and tank are situated five miles nearer the town, at a height of 215ft. above sea-level, and are calculated to pass from 100,000 to 150,000 gallons. A 3in. pipe conveys the water from the reservoir to the filter, and 7in. pipes from the tank to the town. The engineer of the scheme is Mr. W. Henderson, C.E., Dumfries, and the cost of it will be between £11,000 and £12,000.

STATUES, MEMORIALS, &c.

A PUBLIC drinking-fountain was opened at Glosop on Saturday week, the gift of Mrs. Wood, Whitfield House. Messrs. Mills and Murgatroyd, Manchester, are the architects, and Messrs. Williams and Hope, Dinting, are the contractors.

Building Intelligence.

BLACKBURN.—The first school erected by the School Board of Blackburn was opened on Monday last. The schools are arranged in four departments, for 75 babies, 235 infants, 225 girls and 225 boys, making a total accommodation for 750 scholars, with an allowance of 10 superficial feet of floor-space for each scholar, according to the requirements of the Board of Education. The style of architecture is Domestic or Tudor-Gothic. The walls are built of Yorkshire pier-points in broken courses, and the ashlar dressings have been procured from the Howorth quarries in Yorkshire. The slates are green in colour, and the ornamental ridging of a red brown tint. The floors of the schools are laid with pitch-pine blocks in pattern, upon a bed of concrete and cement, and the walls are cemented throughout. The design was selected in competition, and the work has been carried out by the author, William S. Varley, F.R.I.B.A., architect, Blackburn.

BRAMLEY.—A large swimming-bath, situated in Bramley, one of the suburbs of Leeds, has lately been opened. The floor, side, and foot-paths around the bath are made in concrete, the whole of which has proved perfectly watertight. The above concrete has been supplied by the "Eureka" Concrete Co., of 52, Queen Victoria-street, London.

BRISTOL.—A quaint structure, the chapel attached to Barstaple's alm-house, near Jacob-street, at the top of Old Market-street, has disappeared, having been taken down to make room for a new structure. The hospital founded by John Barstaple dates from 1402, when Henry of Lancaster, having put an end to the Plantagenet line by seizing the crown, had reigned three years, and Thomas, Lord Berkeley, was employed in mustering men in Bristol and the surrounding district to oppose the incursions of the Welsh into England. The original building in Old Market-street was in existence till nearly the middle of the 18th century, and was at first more restricted in its accommodation than subsequently. The founder, a merchant, was bailiff of Bristol in 1379, sheriff ten years afterwards, and Mayor in 1395, 1401, 1405. He dedicated his almshouse to the Holy and Undivided Trinity and St. George, and located here six poor men and an equal number of poor women, with a priest to officiate to them. This arrangement lasted during pre-Reformation times; but afterwards the number of inmates was increased. About 1738 the old hospital, having become dilapidated, was removed, and a building which stood for 120 years substituted. This structure was partially pulled down in 1853, to give place to a more finished almshouse. Messrs. Foster and Wood were instructed to prepare plans for the new chapel, and Mr. H. A. Forse, builder, of Charles-street, St. James's, was chosen to carry out the contract of removing one building and erecting another on the site. The contractor, in taking down the chapel, found the date 1679 on one of the stones. As the design of the place was remarkably plain, there were few of the details worthy preservation. Having completed the task of pulling down, Mr. Forse, on Saturday, commenced the wall of the new structure, the dimensions of which will be 40ft. long by 15ft. w.de. The style is Perpendicular, and the chapel will be substantially built of Pennant stone with Bath stone dressings. The whole of the woodwork will be of pitch-pine varnished; the seats will be open, and the roof of timber with curved ribs. The part of the chapel near the Communion-table is to be laid with encaustic tiles. The windows will be filled in with cathedral glass. A corridor will lead to the vestry attached to the chapel, and the entrance to the chapel will be by a porch. The total cost of the undertaking is about £1,000.

BRYNAMMAN.—The Bishop of St. David's attended at Brynamman on Friday, the 15th inst., to consecrate the new church which has been erected there. The building will accommodate 300 persons. It consists of nave 55ft. long by 25ft. wide, and chancel 26ft. long by 16ft. wide. The latter has a small aisle on the south side, and the former a baptistery against the west wall next to a double porch, while on the north side of the chancel a commodious vestry with fuel-chamber beneath is provided. The bell is hung in a western gablet. The walls are built in

courses with the dark grey local stone, relieved by windows and dressings of Westwood stone, and the roofs are covered with light grey slates. The pavements consist of a mixture of stone flagging and Webb's (Worcester) encaustic tiles in patterns. The altar standards were made by Messrs. T. Brawn and Co. of Birmingham. The whole outlay has not exceeded the original estimate of £1,500. Messrs. Balcombe and Price, of Pembroke Dock, have carried out the work. Mr. Hay, of Brynamman, acted as clerk of works, under the directions of the architect, Mr. E. H. Lingen Barker, of London, Hereford, and Tenby.

COMBAMARTIN.—Combamartin, an old-fashioned market town about six miles from Ilfracombe, has now a restored church, or, at any rate, a church suitable and fit for public worship. About thirteen or fourteen years ago the Rector, at his own cost, restored the chancel, and a new reredos was added. The chancel-roof was then put in order, and some new seating introduced. From time to time small additions of seating have been made, and several good stained-glass windows have been furnished. The exterior is considered to be one of the best in the county. It has a lofty and symmetrical tower, with bold projecting buttresses, having foliated niches in the third stages. The principal attraction inside is a carved rood-screen, with paintings of our Lord and the Apostles on the lower panels. In addition to this there is a screen separating the chancel from the north chancel aisle, perhaps one of the finest specimens of oak carving in North Devon. In order to get into the church from the south entrance the parishioners have first to descend one step at the porchway and another three steps into the church. There is a north porch; and the church has a spacious nave, north and south transepts, north aisle, and north chancel aisle. The present works have extended to the plastering of the walls, the cleaning and repairing of the internal stonework, and the reseating of the nave and north aisle. The interesting oak-seating in the north chancel aisle has been refixed and carefully preserved. The whole of the works have been carried out by Mr. Burgess and Messrs. Goss and Sanders, all of Combamartin, under the personal supervision of the architect, Mr. W. C. Oliver.

DEWSBURY.—The corner stones of the new Infirmary at Dewsbury were laid last week. The new institution is being built at the junction of Halifax, Carlton, and Hirst-roads. The main front will be to Halifax-road, and in this will be the visitors' entrance, from which a corridor (7ft. 6in.) runs east and west the whole length of the building. The large general wards will be on the pavilion principle, and placed at right angles to the central building, running parallel with Halifax-road. The corridors will have Dennett's arched fire-proof floors in concrete, finished with cement surface and mosaic tiled borders, and the floor-boards on the ground and first floors will be of oak, French polished. The architect, Mr. Albert Kirk, has adopted the Gothic style, treated in a domestic manner. The main feature of the front will be the clock-tower, rising to a height of 90ft.; in this tower will be the visitors' entrance, over which will be an oriel window with moulded corbels and castellated battlement, prepared at the top for the reception of a sculptured figure representing "Charity." Over the figure will be a carved canopy in ashlar. The tower will be finished with ornamental moulded cornice, with three clock-turrets in ashlar, and covered with wood roof and Westmoreland slates, the whole being surmounted by ornamental iron cresting. At the end of the large general wards will be two angular towers, each rising to the height of 75ft. from the ground, having moulded cornices, and finished with slated roofs surmounted with ornamental iron cresting. The building is being erected with white delph-stone from Hipportholme quarries, with white ashlar dressings from Holbairth. The interior walls will be built of brick. The following is a list of the contractors:—Masons, Messrs. Jas. Brier, Sons, and Wilson, Savile Town; joiner, Mr. George Syles, Batley Carr; plumber, Mr. S. Hoyle, Batley Carr; slaters, Messrs. J. T. Rawsthorne and Co., Dewsbury; plasterers, Messrs. Richardson and Binns, Dewsbury; painter, Mr. J. H. Dyson, Dewsbury; fire-proof arching, Messrs. Dennett and Ingle, London. The clerk of the works is Mr. Alfred Heyworth.

Glossop.—The new Littlemoor Independent Schools at Glossop were opened on Friday week. Native rubble stone has been used for the walls throughout; those towards Victoria-street and the chapel burial-ground (north) being faced with pitch-faced wall-stones from local quarries. All the block stone for the dressings or architectural features of the elevation is also from local quarries, and some red stone from Kincorn has been introduced. The roofs are covered with Venetian slates, and all the internal wood-work is of pitch-pine, varnished. The style is Italian Gothic. A contract was entered into with Mr. Aaron Houghton, of Goley, for the whole of the work, at £2,570. The architects are Messrs. Paull and Bonella, of No. 2, Clumery-lane, London, W.C., and No. 1, St. Peter's-square, Manchester. The total cost is about £2,880.

MANCHESTER.—The foundation-stone of the new Church of St. Edmund, Alexandra-road, is to be laid to-day. The church, parsonage, and site will cost about £11,000. The style is Early English. The church will be faced with Yorkshire stone, with white stone dressings. The total length of the building will be 117ft., and the width 70ft., the nave being 100ft. by 36ft., and the aisles being each 15ft. wide. The chancel is 25ft. wide, and will be lighted by seven large traceried windows, the aisles by 12 double-light windows, and the clerestory by 26 single lights. The church will accommodate 1,000 persons. The architect is Mr. Henry R. Price, 25, Cross-street, Manchester, and the contractor, Mr. James Herd, Ardwick.

NEWBOLD PACEY.—The new church at Newbold Pacey, near Leamington, dedicated to St. George the Martyr, was opened on the 29th of June. It was begun about twelve months ago, and intrusted to Mr. James Kibler, of Wellesbourne, by whom the work has been carried out from plans prepared by Mr. J. L. Pearson, R.A., the architect of Truro Cathedral. The clerk of the works was Mr. H. Timms, of Liddington. It is built on the site of the old church, which possessed no features of interest except two old Norman doorways, a rude specimen of the 12th century. They have been refixed on the north and south side of the new church, which is of Early English type, very simple in its design and ornamentation; it consists of nave, chancel, south aisle, with transept and vestry; the principal entrance is on the north side, under the tower, which stands near the west end. The roofs are of open timbers, covered with tiles. The church itself is built of local limestone, with dressings of Warwick stone, the inside being plastered. The floors are laid with wood blocks under the seats, and tin quarries elsewhere. The altar-space is laid with Godwin tiles, ancient make. The seats of nave and aisle are chairs; the pulpit, which stands on a stone base, is of oak, with tracery panels and carving; the stalls are of pitch-pine. A tracery screen separates the chancel from the vestry and organ-chamber. The altar-table is raised five steps from the nave-floor and is also of oak. The font is octagonal, with clustered shafts; it stands under the west window. The building is warmed by an underground stove, with a pilot-stove in vestry. The carving of the pulpit was done by Mrs. G. Greenway; the font, the work of Messrs. Jones and Willis, of Birmingham and London, was the gift of Capt. Nichols; the organ was given by J. M. Paterson, Esq.; the cost of the building is about £2,600, and will seat about 200 people.

NEWCASTLE-ON-TYNE.—St. George's Church, Newcastle, which has been closed since Easter Sunday and has undergone a thorough restoration, was reopened last Friday. The church was erected about 53 years ago by the Ecclesiastical Commissioners, and is of the style of Gothic architecture in vogue at the commencement of its revival. About two years ago considerable alterations were made to the east end, as far as the funds permitted, by the formation of a chancel out of the eastern bay of the nave, and the formation of a proper choir therein. The completion of the whole scheme of restoration has now been carried out by the removal of the high-backed pews, the rearrangement of the aisles, and the re-roofing of the whole church with open benches of pitch-pine. The interior has been cleaned and painted in a plain but thoroughly effective style. The old stone paving has been removed from the aisles, and new tile paving substituted for it. The

projecting part of the west gallery has been removed, and the remaining part of this gallery over vestries has been re-seated and a new front of pitch-pine added, the design being a remarkably neat one. A new font, by Jones and Willis, of Birmingham, has been fixed near the south door. Just before the closing of the church on Easter day of this year, a new stained-glass window, by Messrs. Hardman, of Birmingham, was opened at the east end of the south aisle. Since then the old east window has been removed and a five-light tracery window substituted. This will shortly be filled with stained glass by Messrs. Hardman, and is the gift of Mr. H. Coghill. A new tile reredos is in course of preparation by Messrs. Minton, Hollins, and Co. The whole of the works have been carried out by Messrs. H. and R. Inskip, of Longton, from the designs and under the superintendence of Messrs. Thomas Lewis and Son, architects, of Newcastle. The cost of the restoration has been about £1,400.

SALISBURY DIOCESAN CHURCH BUILDING ASSOCIATION.—A meeting of the general committee of this association was held in the Board-room Close, Salisbury, on Tuesday week, the Very Rev. the Dean (in the chair), Rev. Chancellor Swayne, Rev. Canon Hatchings, Rev. Tapper Carey, Rev. W. P. S. Bingham, Mr. John Jeffreys, and the Rev. Sir Talbot H. B. Baker, Bart., and the Hon. and Rev. Canon Gordon, diocesan secretaries. In the case of Chideock Church, in the rural deanery of Bridport, Dorset, where an extensive work of restoration has been carried out, the committee ordered payment of a grant of £100, which had been previously promised. An application was next considered from the Incumbent of Christchurch, Warminster, in the rural deanery of Wylde, Wilts, for an increased grant, in consequence of its being found necessary to expend about £1,600 in the restoration, re-roofing, and other works proposed to be done to the parish-church, instead of the more limited alterations originally decided on, and it was, therefore, determined to add £50 to the £50 promised at a previous meeting. In the case of Manningford Bruce, in the rural deanery of Marlborough, Wilts, where an increase of accommodation in the parish church is in contemplation; permission was given to proceed with the work, the subject of the grant to be considered at a future meeting. The remaining case was South Wroxall, in the rural deanery of Potterne, Wilts, the application being for a grant to increase the accommodation in the parish-church, by rebuilding the chancel and restoring the entire fabric. It was decided to refer the matter to an architect, and to make a conditional grant of £10, subject to such reference.

SALTON.—The ancient parish-church of Salton-in-Rye-lake, near Mutton, was reopened on Tuesday after undergoing restoration at a cost of about £2,000. The church is dedicated to St. John of Beverley, who was formerly a prebend of York. It was originally built about the year 1100, and perhaps a few years before Archbishop Thurstan gave it to the Priory of Hexham. There are no traces of work earlier than the Conquest in the church. The tower has been carefully restored. The wall in many places on the south side has been partially taken out and rebuilt; the lower part of the tower cut off from the nave by an oak screen, so as to form a vestry; and a three-light Perpendicular window inserted in its west face, in place of the original lancet, to give light to the vestry and the west end of the nave, which was very dark. New floors have been provided, and the bells rebung in new oak frames; the belfry windows repaired, and on the old corbel-table has been erected a parapet, formed out of that removed from the nave. Other important alterations in the details of the interior have been carried out, more especially in regard to the flooring and the windows, and the whole of the work has been efficiently done by Mr. J. Wood, of Pickering, from the designs and under the superintendence of Mr. C. Hodgson Fowler, F.S.A., of Durham.

St. Clement's Church, DARTINGTON.—The *Nottingham Express* says: "Those of our readers who read Mr. Pritchett's history of this building, which appeared in the *Dartington and Richmond Herald*, will remember that the chancel had carved oak panelling behind the stalls until 1778, when it was removed by Lord Viscount Vane. It was, we understand, Mr. Pritchett's wish, in restoring the chancel some fifteen years since,

to replace this; but the funds then at his disposal did not allow it. The Duke of Cleveland has, however, as lay rector, now instructed him to carry out this improvement; and the churchwardens have agreed to remove the unsightly hot-water pipes which disfigure the front of the stalls, so that gradually we may hope to have the church finished."

WALSALL.—On Wednesday week the foundation-stone of a new Presbyterian church was laid at Walsall. The internal dimensions of the church are: length, 63ft. 6in.; breadth 15ft. 9in.; height, from floor to ceiling in centre, 35ft. Sitting accommodation will be provided on the ground-floor for over 400 adults; and, including the additional sittings in the gallery over the main entrance, the sacred edifice is computed to accommodate about 500 persons. The schools comprise a large room 32ft. 6in. by 21ft. wide, and four class-rooms, varying in size from 12ft. by 7ft. 6in. to 15ft. 6in. by 11ft. 6in., thus securing a total accommodation for upwards of 200 children. The buildings have been designed in the Gothic style, of the early 14th-century period, and are to be constructed of brick, faced on the fronts with best local pressed bricks. The contract for the various works has been taken by Messrs. William Trow and Sons, of Wednesbury, and they are now proceeding with the buildings, from the plans and under the superintendence of Messrs. John Cotton and H. H. McConnell, joint architects, of Birmingham and Walsall, whose designs were selected some three years ago. The cost of the buildings, including lighting, warming, and furnishing, is estimated at about £3,000.

WIMBORNE.—Wimborne Church, having undergone a thorough restoration, was reopened on Thursday week. Such portions of the wall as had become dangerous have been made good, and such as were past repair rebuilt, but every old stone carefully replaced in its former position—just as it formerly stood, the stones having been numbered and replaced. All the principal timbers to the chapel are original, but the boarding and paterae are new. The turret, which has replaced one of modern date, is also new. The floors have been relaid with Godwin's encaustic tiles. While the restoration was in progress interesting work was brought to light. The architect was Mr. William Jeffrey Hopkins, of Worcester, and the builder Mr. Stanley, of Broom. The carving is by Messrs. Martyn and Emms, of Cheltenham.

COMPETITIONS.

BIRMINGHAM AND MIDLAND EYE HOSPITAL.—An adjourned meeting of the committee of this Institution was held on Friday, the 22nd inst., for the purpose of selecting a design for the reconstruction of the hospital. Six sets of drawings had been submitted by the invited competitors. Those under the motto, "Mens tunc ego" received the greatest number of votes, and the authors, Messrs. Payne and Talbot, of Birmingham, were appointed to carry out the work.

CHIPS.

Three members of our Designing Club have passed the Advanced Stage Building Construction Examination, all being students of the Colchester Art Classes and pupils of Mr. G. Gard Pye, A.R.I.B.A., of Colchester. Mr. E. Farman passed the elementary, Mr. C. Dickinson the advanced, and Mr. G. A. T. Middleton the honours stage. Mr. Butler, a clerk in another architect's employ at Colchester, and a student of the Art Classes, also passed the advanced stage.

Lady Yester's parish-church, Elinburgh, was closed on Sunday last for the purpose of alterations on pulpit-stairs, choir, and session seats, which will be enclosed with new open rail. The old pews are to be lowered, and the doors on the whole of the pews are to be taken off, and new soffits at end, and book-boards made flat. The windows are to be reglazed, and the whole church painted, and to be lighted with coronas instead of the present sunlight. The estimated cost is about £500, from plans prepared by Mr. J. A. Dorell, architect, Elinburgh.

A patent has been granted, according to the *English Mechanic and World of Science*, to O. Saydel for supplying pure air to cities by conveying it in pipes from the sea-shore and delivering it to houses through suitable taps. It is numbered 5,281, 1880.

"To a practical man with a taste for mechanics, and the bumps of constructiveness fairly well developed, we can conceive no higher mental rest than a couple of hours spent over the June numbers of that truly marvellous publication the *English Mechanic*. In a hundred and fifty odd pages that make up the bulky mass of letterpress, there is recondite information on almost every conceivable subject, ranging from how to construct a mouse-trap, to the latest method of calculating the phases of Orion."—*The Brightonian*. Price Two-pence of all newsmen, or post free 2½d.—31, Tavistock-street, Covent garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is ONE SHILLING for TWENTY WORDS, and Sixpence for every eight words after. All Situation advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in serial advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) for any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33fr. 30c.). To India (via Brindisi), £1 10s. 10d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

Mr. CHARLES WILSON, of 13 and 15, Light-street, New York City, is authorised to receive American subscriptions at the rate of 6 dols. 40c. per annum.

Mr. R. M. TUTTLE, of Titusville, Penn., U.S.A., is also authorised to receive subscriptions at the same rate.

Cases for binding the half-yearly volumes, 2s. each.

NOTICE.

Now Ready.

Vol. XL, Price 12s. A few bound volumes of Vol. XXXIX, may still be had, price Twelve Shillings; all the other volumes are out of print. Most of the back numbers of former volumes are, however, to be had. Subscribers requiring any back numbers to complete vol. just ended should order at once, as many of them soon run out of print.

VENTILATION OF SOIL-PIPES.

To the Editor of the BUILDING NEWS.

SIR,—I have read the remarks upon this subject from Mr. Michael Drury, on page 87, and from Mr. W. H. Willett, on page 119. The former makes several mistakes, e.g., he so writes as to give the idea that the smallest air-hole in a pipe upon the outside of the trap will prevent siphon action. Now, that is wrong. I have seen the letting off of a Bramah closet suck the water out of a bath-trap 12ft. from it, even when said bath-trap had a 2in. air-pipe!

As to a ¾in. composition gas-pipe being a sufficient ventilating pipe for a soil-pipe of any length, that is an error; it is better than nothing, and helps to prevent concentration of the sewer-gas at the top of the pipe; but for actual service it is something equivalent to feeding a man upon a farthing biscuit a day, while to prevent siphonage where Bramah closets are used, or large quantities of water sometimes sent down the soil-pipe at once, said ¾in. pipe is too small. It also prevents sufficient fresh air from passing through the pipe. Further, the use of a thin compo gas-pipe upon a soil-pipe belongs to the cut-and-run or scamping style of doing the work.

Mr. Drury's criticisms upon Mr. Hellyer's objections to the Mansergh trap are not to the point, and the idea of a trap being thoroughly "ventilated by a ¾in. pipe" is simply laughable. With only a ¾in. inlet and a long ¾in. pipe "bent round spouting and other projections"

for the outlet, the ventilation that could then take place seems to me to belong to the region of the imaginary.

In regard to Mr. Willett's statement that he prefers to use a simple earthenware water-closet which contains its own trap (all being above the floor), instead of a w.c. with a trap under the floor, and metal apparatus and container, I think he is on the right track. The simpler water-closets are, so being they are efficient, and all above the floor, so much the safer are they, and cheaper and easier to keep up.

Mr. White says he uses Stiff's "intercepted traps" in combination with an Archimedean screw ventilator for his soil-pipes. I fear the use of said combination as described is an infringement of my patent of April 23rd, 1875, unless Mr. Willett can point to published data prior to this date showing public use of the combination before me. Can he do so? If not, he ought to use my improved traps in the combination he describes.

As to the use of the Archimedean screw-cowl upon the top of the soil-pipe, I beg to say that although I at one time mentioned it for that purpose, experience in its use now causes me to condemn it. I do not now approve of any rotating or movable cowl, with the wind for its motive power, being used when far better and cheaper fixed cowls can be got to serve the purpose, more especially as there is no liability of the fixed cowl to get out of order, stand the wrong end to the wind, or stick fast. When the screw-cowl sticks fast its blades prove a great obstruction to the passage of the air in the pipe. They are also an obstruction to the temporary passage of air quickly down the pipe, to prevent siphon action when the closets are let off.—I am, &c.,

W. P. BUCHAN, S.E.

21, Renfrew-street, Glasgow, 23rd July.

SANITARY PLUMBING, AND PLUMBERS' WORK.

SIR,—Your correspondent, Mr. P. J. Davies, does not mention that Mr. Hellyer offered him 10 minutes at the close of the lecture, to reply to any remarks made in reference to the Bramah closet having a trap. Mr. H., as I understood, said that in the specification the trap was not mentioned, therefore he could not agree with Mr. D. And as Mr. D. made such a miserable attempt at proving that Bramah did fix a trap under his closet, Mr. H., as far as I could judge, only expressed the opinion of, at least, a part of the audience present, when saying that "Mr. Davies was not worth smoke," and through Mr. D. failing to defend his argument, he greatly disappointed many present, who expected to hear a good discussion, which, instead of lasting 10 minutes as intended, scarcely one minute had expired before Mr. D. resumed his seat.

As to Mr. H. taking his glass trap away from his model, was he not illustrating that the soil-pipe continued full-bore up to the roof was sometimes really no ventilation, unless air was admitted at the bottom; so why should he remove his trap? For according to Mr. H.'s showing, smoke, or sewer-air, would not always rise up even a perpendicular pipe, unless assisted by a current of fresh air, and had he removed the trap fixed at the foot of his model, as "Mr. D. wishes in his letter of the 22nd inst.," it would then have been simply no experiment whatever.

As to Mr. D.'s question on hydraulics in reply to my letter of the 15th, does he wish us to believe that the water leaving the w.c. apparatus strikes against the sides of the trap and thus escapes into the soil-pipe, never falling on and covering the surface of the water in the trap? Really this is something novel, and requires an explanation from Mr. D. I am glad to see that Mr. D. is prepared to prove, as he imagines, the superiority of the trap; the present is a good time, so why does he not practise what he attempts to preach, and let us have the proof? It will certainly not be by such means as Mr. Pullen advocates through his circular, for a visit to South Kensington and Parkes' Museum, will quite upset the greater part of that theory; in fact, nearly opposite to Mr. Pullen's stand in the Medical and Sanitary Exhibition there is an old trap shown (and anyone can inspect it); the interior is covered with foul matter, and quite corroded through the top in no less than three places. How does this agree with according to Mr. P. and Mr. D.'s ideas—namely, "it is never in the body of the lead that the leakage occurs, but at the joint's of the trap"? Now the

trap I mention proves this to be incorrect, for the joint or solder is perfectly sound, whilst the lead is perforated by the action of the sewer-air, again proving that Mr. P. and Mr. D. are wrong, and showing that the trap even requires ventilating. I cannot but think that to the pitiful opposition shown by Mr. D. and his friends to Mr. H.'s lectures, we owe the omission of the last lectures, besides not having the others in a more complete state, for Mr. H. must have been at no little trouble and expense, and had he had the encouragement he deserved, I believe he would have endeavoured to practically illustrate much further by experiments his ideas; but as so much opposition is shown with regard to the first course of lectures given to us, we must expect that others desirous of taking the subject up, will think twice before attempting to do so, thus preventing, to my thinking, what might have been most beneficial to all interested in this subject. I am, &c.,

Lambeth, July 27.

H. B.

BUILDING-STONES.

SIR,—On reading your correspondent's (Mr. D. A. Masey's) remarks on the way in which bad stone is often used unknown to architects, I could not but endorse his opinion, I am well aware myself that the reputation of Caen stone has been much damaged in this country by being in many cases used otherwise than on its proper bed, to avoid cutting other blocks, and thus save cost. Also, I know for a fact that, thirty years ago, when the Caen-stone trade was then in vogue in this country, and the demand was almost too great for the supply, anything was sent over, and with gratuities to foremen and others, the stone was accepted.

With such doings it is not strange that we should now reap the bad results.

I can say that where I have supplied Caen-stone within the last fifteen years I have had nothing but praise for its quality. I think it would be always well if the architect would correspond with the stone-merchant.—I am, &c.,

EMILE FOUCARD.

London, 23rd July.

COMPETITIONS: A THOUSAND DOLLARS DOWN!

SIR,—I have just come across a story from "the other side," the moral of which is obvious. A New York architect was requested to send a design in competition. He asked for a thousand dollars down. This quite staggered his "friends," to whom, however, he at once explained that the money would not be for his professional services. "But anyone," said he, "who prepares a design for a building committee to decide upon is a fool; and I think I should be paid at least a thousand dollars for making a fool of myself."—I am, &c.,

Leigh.

J. R.

COOPER'S HILL COLLEGE.

SIR,—In your report of the Duke of Argyll's speech, his lordship is made to say that, "the Indian Government annually lost enormous sums of money by the carelessness and incompetence of the Civil Engineers in India." If for *Civil* he had said *Royal*, he would have been much nearer the mark.

Again, he says many of the new barracks "were so insufficiently built that it was found they would not last more than a few years, and in some cases even the lime that had been used was pronounced to be bad." His lordship seems to forget that the *Executive Engineer* in charge of the Sangar Barracks at the time of that scandal was Captain F.—, of the *Royal Engineers*.

"Give the devil his due" is a good old maxim; and, although I am far from considering the C.E. element in India as immaculate, I like to see fair-play.

Cooper's Hill was the offspring of the fertile brain of Col. Chesney, R.E., and had it not been for his personal influence and excellent management, it would probably have collapsed years ago. The place was not required, and so the Duke of Argyll would have found had he given the open market of Engineers a fair trial, which he and his satellites never did. Now, the young engineers learn their work in India to the vexation of their superiors, and at the cost to the Exchequer of £420 a year each. When they have learnt it, I do not deny that a large pro-

portion turn out well. It is a mere question of £ s. d.—I am, &c.,
25th July. PETER PLAYFAIR, C.E.

FRESH-AIR VENTILATION.

SIR,—Permit me a brief comment on Mr. Willett's letter in your last week's B.N., wherein he testifies "that the fresh-air method of ventilation is far in advance of any others." He does not even hint that he has ever tried the small pipe vent. I have tried it; with or without a "fresh-air method": it is equally successful; hence I conclude the "fresh-air method" is only a superfluity. Still's "Interceptor" is very good, but it will not, of itself, prevent the siphonic action of a trap; nor will it prevent the generation of noxious gases in the soil-pipe and the branch therefrom to the w.c. basin, and the consequent probable accumulation of such gas in the apex of the w.c. trap. To secure these great desiderata, there must be an ever open vent in the apex; this is the one thing necessary which will effectually prevent any accumulation, destroy the possibility of siphonic action (the greatest evil of w.c.s.), and also secure safety even in the rare cases where a trap is nullified through evaporation. Roughly estimating the specification quoted in the letter, a special cost exceeding £10 is involved by the very complicated system thus developed. I maintain that the full advantages thus painfully secured (and something more of the greatest importance) is to be obtained with an outlay of about 5s.—I am, &c.,

MICHAEL DREY.

Lincoln, 25th July.

SURBITON COTTAGE HOSPITAL COMPETITION.

SIR,—Can any of your readers inform us what has been the result of the above? We sent designs some time ago; but the committee, with the courtesy usually extended to competing architects, have neither acknowledged their receipt nor replied to our letters asking for information.—Yours, &c., E. AND G.

BUILDERS.

SIR,—An assertion so sweeping and unfair as that made by Mr. Philip E. Masey in your last journal, relative to builders, should not pass without some protest. Connected with the office of the late Sir Gilbert Scott from the days when it was "Scott and Moffatt," to the present time (some thirty years or more), tempts me to think I have seen somewhat of builders, good, bad, indifferent, varying from the specimen which "neither treaties could bind, nor oaths render firm," up to men like the late Mr. Ireson, of Northampton, whose dimensions, even in the case of a disputed settlement, I should have taken without doubt, or question of their accuracy. Many builders, in truth, are men of the highest honour, the major part (thank Providence for it), fair tradesmen, who, if dealt with in a proper business way, are reasonable enough. Some, as in other trades (and professions also), no doubt, desiring to find "the reter of their tethers" when they begin, but, when once found (along with the fact of the architect desiring but honest action), will give satisfactory works, provided the clerk of works fairly represents his master, cannot be bought, and is properly supported in his duties when right is on his side. To the above testimony that of the whole older members of the Spring-gardens office would, I doubt not, correspond.

Mr. Masey must certainly have rambled Jericho way in the West; but ought, with a little caution, to have enjoyed when even dealing with Bristol builders, a few hours' calm sleep of both his eyes. My own experience in their case was, on the whole, much more kindly, for, if obliged to "use a lantern" at rare moments (a thing not unknown elsewhere), it never, after all, became necessary to perform a promise of "sleeping with two legs out of bed and two eyes open," once made in reply to Sir Gilbert's jocular caution respecting the smartness of the craft in that watchful city, and I had a good deal to do with them.

On the Bath-stone question, I would venture to ask Mr. Masey if it can be right for an architect to leave to the sole responsibility of either the clerk of works (his servant), the quarry master, or builder the settlement of what is good or what is bad Bath stone—one so easily settled,

provided the architect will but visit the various quarries and obtain the knowledge of a question he can there so readily obtain, and of which question ninety-nine in the hundred of his clients expect, and fairly so, that he should be able to settle for their protection? Surely the architect must be the proper person, and none other.—I am, &c., JAS. THOS. IRVINE.
Lichfield, July 25.

BAGSHOT CHURCH COMPETITION.

SIR,—I am entertained by the perusal of the letter in last week's News, as Mr. Rayne, the acting hon. sec., wrote me practically the same letters.

I was much annoyed, however, to have my drawings returned, and to have to pay the carriage. I immediately thereupon inclosed the receipt to Mr. Rayne, requesting him to remit the amount.

If this meets his eye, he may learn that the charge of eightpence stands against him in my books, and that I should be glad to know who is the chosen architect.

ANOTHER COMPETITOR.

ABBOTT'S HOSPITAL, GUILDFORD.

SIR,—In reply to "E. L. L.'s" letter in your last, my reason for doubling the final £ in Abbott is obvious, as furthering the important distinction I desired should be made in my previous letter. My chief authority is long usage. I have no tomb, will, or charter to refer to; the only reference I can make is to the headings in rewards received during my long term in the school, and these, inserted by the authorities at that time, support my view—possibly, a modernised one.

I regret under the initials I fail to recognise my old schoolfellow, but beg him note—I am, &c.,

JOHN (not James—another lapsus) WILLIAM STEVENS.

Intercommunication.

QUESTIONS.

[6579].—**Nave Roof.**—Will some one kindly give a section of a portion of a church nave roof span, say, 30ft., pitch 50ft., wall 2ft. 3in. thick, showing the bearing, scantling, and best method of framing the principal rafter with curved brace and tie beams together at the foot? What are the usual scantlings of the rafters, purlins, and ridge in a roof of this description? How are the common rafters and inner and outer wall plates framed together and in relation to the principal? Should the inner plate be moulded, and how is the spout fixed? Is there any recognised method of finding the correct proportion of an Early English window, and of the pier and chancel arches of this style? Is it usual for the window-heads inside to have the same play as the jambs? How are the angles treated when the walls are stuccoed, and what is the usual height from the top of the sill of the aisle windows to the floor line?—STUDENT.

[6580].—**Floors for Dancing.**—I should feel much obliged if any one would give me any information regarding swinging floors for dancing on. Have any been constructed, and where? I have to put one up 70ft. by 35ft., and shall feel obliged for any information. I hear they consist of beams or rolled joists which carry the flooring planks, the former being suspended by chains, and resting on indiarubber blocks to give the necessary undulation.—S. F. C.

[6581].—**Timber Building Construction.**—I contemplate building a timber engine-house of about the following dimensions:—70ft. by 20ft. and 10ft. high to wall plates. I shall be glad to have any hints on the matter from any one who has had experience in such construction. I wish especially to know if feather edged weather boarding or vertical planking is the best. In the latter case the building would be planked with boards, say, 1 1/2 in. by 7 in. spaced 1 1/2 in. apart, centre to centre. This would have a clear space of 1 in. between the boards which would be covered with boards of the same size, lapping 1 1/2 in. over each edge, where they would be nailed.—PITCH PINE.

[6582].—**A Local Board Difficulty.**—I shall be glad if any of your readers can inform me whether it is possible and my proper course to adopt to compel the authorities of an inland watering place to provide a new sewer or to deepen an existing one which is found to be but 3ft. from the bottom of it up to the surface of road, as they refuse to pass plans of a proposed house because the floor of basement (consisting of larder, coal, and wine cellar) is 2ft. below the level of sewer, which, I should add, is at the head of the street, on high ground, with no fear of flooding, and full 50ft. distant from the proposed cellars. The stipulation of the authorities for a drain from the floor of cellar, besides being objectionable, practically forbids my client having any basement at all. A drain in basement being unnecessary, can the authorities be compelled to pass the plans without one, the drainage in all other respects being approved?—M. G. L. B.

[6583].—**Cast-Iron Tubes.**—I will be obliged to any correspondent who will furnish me with accurate data for ascertaining the thicknesses to be given to test iron tubes or pipes to withstand external pressures. The several treatises written upon the resistance of tubes to collapsing do not quite give me the information I want. For particular reasons, I propose inserting cast-iron tubes under shallow railway embankment, in lieu of the ordinary masonry culvert or timber box-drain. One of the

pipes or tubes will be 6ft. 9in. wide by 5ft. high (oval shaped), another will be a circular pipe 4ft. in diameter, and a third will be a circular pipe, 3ft. in diameter. The tubes will reach up to under-side of railway sleeper, so that the entire weight of the engine carried by the driving-wheels will represent the greatest weight to be carried, and this weight I have assumed as being twelve tons. Assuming, therefore, that a sleeper is laid immediately along the top of each tube, what thicknesses are required in each case? I will be glad to have an accurate formula and note of any experiments made.—HOLLOW CYLINDER.

[6584].—**Party Wall.**—Is not one of the owners of a party wall entitled to raise it by giving notice to adjoining owner?—SCOTLAND.

[6585].—**Soil-Pipe.**—Will some one kindly give short description, with sketch, showing manner of forming disconnection between soil-pipe and drain, so as to leave discharging end exposed to the atmosphere as advocated in Mr. Hellyer's lecture?—EARL STEEFOLD.

[6586].—**Testing Iron Girders.**—Would any of your experienced readers inform me as to the method adopted in testing iron girders, description of means of testing, &c. &c.—LEARNER.

[6587].—**Plunge-Bath.**—Will some one who has experience be kind enough to inform me the best method of forming a suit water plunge-bath below the ground, size about 25ft. by 60ft., and 3ft. 6in. to 6ft. deep? Will concrete do, with clay puddling at back, or is it best to build it in brickwork, with glazed brick lining?—ASSISTANT.

[6588].—**Measuring Paintwork to Windows.**—A little book on Quantities that I have seen commence by telling the reader to "take the total width from out to out of architraves, by the height from under-side of window board to top of architrave. Is this the actual method pursued by surveyors? The resulting superficial area is nearly all glass, which, of course is not painted at all.—PAINT.

[6589].—**Sashes and Frames.**—Will some of your readers kindly inform me what is the standard size in measuring sashes and frames at per foot super, which super less than 15ft.? I am told that if they super less than 15ft., that 15ft. are always charged for! Is this so or not?—DOVER.

[6590].—**Oak and Pitch Pine.**—I shall be glad if any of your readers can tell me the best way of finishing oak and pitch pine work exposed to the weather. If oak is only oiled, I notice that after a year or so the work looks very bad, and it seems to be seldom thought necessary to re-oil.—OMEGA.

[6591].—**Cracks in Concrete Walls.**—Are cracks in concrete walls ever caused by shrinkage of material, or must they manifest some structural defect, such as thrust or roof or bad foundation?—J. F.

[6592].—**Cistern.**—Would any correspondent oblige by stating the strongest manner of constructing a cistern of wood 1 1/2 in. thick, 10ft. 6in. by 4ft. 6in. by 4ft. deep to hold 1,000 gallons of rain water.—R. S.

[6593].—**Gas-Tar Asphalte.**—Would any reader kindly inform the writer what it is that is mixed with gas-tar, instead of boiling the tar, in making asphalte for walks, &c. &c.—MOWERAY VALE.

[6594].—**Floors.**—In a house which has recently come under my notice I find the floors are invariably wet in dry weather and dry in wet weather. The floors are formed of concrete and Portland cement, the level of which is about 5ft. below ground-level. The house stands upon a clay soil, and the land in locality is drained by means of agricultural drain-pipes laid about 3ft. below surface of ground.—W. Y.

[6595].—**Ranges with Firebrick Ovens.**—I should feel obliged if any reader could inform me if ranges or kitcheners with firebrick ovens are to be had at a price that would allow of their being put into good cottages. I have inquired for them at some London houses, but cannot get them. It is for bread baking chiefly that I want them.—J. T.

[6596].—**Measuring Drawings, &c.**—I. Would any reader tell me if he thinks it advisable, in making measured drawings of a building on the spot, to use the mathematically divided paper in squares of twelfths of an inch, in preference to using a scale board, T-square, &c. &c. 2. Which is the shortest way from Stamford to Lyveden (New Building) so as to entail as little walking as possible?—ARTHUR CLAPTON.

[6597].—**London Bridges.**—I should be glad if you or any of your numerous readers would kindly inform me where I can quickly find an account of the construction of any one of the Thames bridges—say, Blackfriars, Charing-cross Railway, or Westminster-bridge; also of the Thames Embankment?—BESRA.

REPLIES.

[6541].—**Canada.**—I would venture to advise "Glasgow" that he weigh well the following facts, which may determine his future course:—1st. That the great Canadian Pacific Railway will not, for years to come, afford any employment for architects. The manner of settlement along the line of some 1,500 miles being very scattered, villages being what Dickens' "Eden" consists of, viz., paper, &c. 2d. The principal cities on the route affording employment to architects being Winnipeg and Emerson, and both of these are amply provided for in the architectural line by my young men, who, having a thorough knowledge of the habits and requirements of the country, and possessing the requisite knowledge, have gone west to touch it for the present, that they may stand a chance in the future. 3d. Our older cities are well supplied, and with men who know what they are about. Even in this immediate neighbourhood there are gentlemen in practice who served their articles with Street, Emerson, Brooks, the late Sir Charles Barry, and Sir Ed. Smurke; but with all it has been a great struggle, and now they have educated a generation of pupils who, by the personal connection of their parents, step into a good practice. It is not of any importance here to be able to boast of English experience, being perhaps, excepting art knowledge, of very little help, rather

hindrance. We have here no quantity surveyors, or any helps of that kind, and so a man must have a very good drilling in the art of writing a clear and lucid specification. I may say that in this province of Ontario the most go-ahead and richest part of this vast dominion of Canada, the feeling of the profession, aided by the judges of the principal courts, is strongly in favour of a bill of incorporation to architects with compulsory diploma—the same as is now required of all practising surveying. I see that you, and my old friend, Harry Hems, contemplates a tour here; but if your correspondent "Glasgow" will take the advice of one who has practised here for 11 years, he will not be hastily advised to come out. May your esteemed periodical long continue to be a weekly treat to—J. ADEE FOWLER, Architect, Toronto, Ont., July 4, 1881.

[6553].—**Top-light for Public-room.**—Read the leading article in *Building News*, Oct. 2, 1874, "On Light." There are formulae for calculating the superficial area for light-openings, but none are to be depended upon. The Pantheon at Rome is lighted by a single eye at the crown of the dome, the area of which gives about one square foot of opening for every 3.3 cubic feet of space in the building. A far larger proportion of opening would of course be necessary in this country; in some picture-galleries it approaches closely to half the area of the ceiling. It is better to have too much light than too little, as blinds can subdue it when too strong; but if insufficient, the ceiling would in all probability have to be renewed. Also use double glazing, to interpose a layer of air of medium temperature between the exterior and interior when required, as large windows and skylights are often a source of cold owing to draught or the sudden cooling of the warmer internal air. For hospital windows, one superficial foot of opening is recommended to every 50 cubic feet, half this should be sufficient for a top-light.—HUGH McLACHLAN.

[6554].—**Decoration.**—As "Occupier" has painted the upper part of his walls, I would certainly not recommend him to have any fancy paper as a dado. The dado should also be of a plain colour and might be painted chocolate. I have seen large sheets of brown-paper used as a dado, it proved very effective having a tinge of green; it has also the advantages of being without gloss, very substantial and economical. A bold yet simple stenciled bordering in black would also be advantageously used above the skirting, and at the junction of dado and upper part of wall.—HUGH McLACHLAN.

[6555].—**Covering Concrete with Plaster.**—Plaster of Paris is far too soft a material to use as covering to a floor. In salenitic cement, plaster of Paris is mixed with ordinary lime, sulphuric acid being set free from the former during the union of the two materials. Possibly this is what "G. B." refers to. I have never heard of tartaric acid being used with building materials, though it is a necessary for baking-powder and effervescent drinks. "G. B." should use as a covering to his concrete-floor Portland cement with two of sharp sand.—HUGH McLACHLAN.

[6556].—**Veneering Round Column.**—I believe the information required is to be found in Gwilt's "Encyclopedia."—HUGH McLACHLAN.

[6557].—**Natural Wood-Finishing.**—Let the marks caused by working with the plane and chisel remain visible, use no sand-paper. When fitted together, the work may be left plain or dead-polished. French-polish and plain varnish may also be allowed, but no staining.—HUGH McLACHLAN.

[6558].—**Staircasing.**—The most recent work on this subject appears to be "Walton's New Treatise and Practical Guide to Staircasing and Hand-railing," illustrated with forty plates. A long critique on this work appeared in the *Building News*, June 8, 1877, in which other works were referred to, the price was not stated. The following works on the subject are by Mr. R. Eddell:—"Carpenter, Joiner, Stair-builder, and Hand-railer," fifty-nine plates with cardboard models of wreaths, thick imperial 4to., cloth, £1 18s.; "Riddell's New Elements of Hand-railing," forty plates, 4to., cloth, 17s. 6d.; "Seventeen Additional Plates to the First Edition of the New Elements of Hand-railing," imp. 4to., 5s.; the first-named work includes the two latter, and the "Carpenter and Joiner," was published about 1874 at £2 5s. Also "Nicholson's Practical Carpentry, Joinery, and Cabinet-Making," revised by T. Tredgold, with plates, 4to., cloth, published at 3s. (in Mr. Batford's recent lists at 16s.; I believe this to be a useful work, and is to a great extent the foundation of the more recent work of Mr. Scott Burn to judge from appearances. "Nicholson's Staircases and Hand-railing," thirty-nine plates, 4to., calf, ss. 6d., published 1829. "Newland's Carpenter and Joiner's Assistant," numerous plates and woodcuts, half bound, £1 18s., published at £2 18s. "Jen's Orthogonal System of Hand-railing," with practical illustrations of the construction of stairs, second edition, 8vo., 5s. post free. Read *Building News*, March 9, 1877, pp. 254 and 255, also March 16, 1877, p. 278 and 279. Any good work on Joinery and Gwilt's "Encyclopedia" also give information.—HUGH McLACHLAN.

[6559].—**Well Pudding.**—Well puddle should be of clay, well tempered with water, sufficient small sand being introduced to bind it together, but not to allow the water to percolate. It should be placed in layers about 9in. thick, and should have not less than two layers, though one correspondent considered that 12in. was sufficient thickness. The thickness of brickwork should be that of a semicircular arch fully loaded of the same diameter as the well. This is not generally considered; the pressure of the earth being forgotten; hence so many wells have the brickwork distorted, with the further result of breaking up the puddle and allowing surface water to penetrate freely.—HUGH McLACHLAN.

[6560].—**Defective Rain Water Tank.**—It the "User" does with his tank as "G. H. G." suggests in your issue of July 15, 4in. brickwork will be sufficient. "The User" should take care that the new brickwork is close up to the old work, and well flushed up at the back.—C. F. M.

[6562].—**Defective Rain-Water Tank.**—To prevent percolation, after a tank has been built, is a somewhat difficult and tedious job; but with such a thickness as 4in. and a little perseverance, the work

ought to be accomplished. I have on several occasions adopted the following method with success:—If coated with cement, take off the cement where the water percolates. Take out the joints as for plugging, and fill up the spaces with tallow, which must be well forced in. Nothing is handier than candles cut to suit length of joint taken out. If there is much pressure, small plug driven in the joint will prevent the tallow from being forced out. The foregoing may seem a somewhat unscientific method of proceeding, but will prove effective if carefully executed, that is if the bricks are not of such a nature as to allow the water to pass through them. The cementing may be made good after the percolation has been stopped; but it is quite useless to attempt doing so before.—Buck-LAYE.

[654].—**Disputed Contract.**—Having seen the question asked by "J. McD." and having had great and lengthened experience in the class of work he inquires about—i.e., concrete floors—and, although he asks for a direct answer from Mr. Hugh McLachlan, we trust he will pardon us for taking the liberty; but we thought it would certainly do him no harm to have the opinion of more than one party. We notice "J. McD." says that "the ground on which this floor is formed is soft and damp, and that the concrete must be 2in. thick." When we have any floor to lay 2in. thick, whatever may be the nature of the ground on which it is laid, the exception being rock, we insist upon having not less than 5in. hard debris or ballast put down and well rammed. If the bottom be very soft, a greater depth than 5in. But we may say, regarding the concrete, that we never on any account whatever, use sand in floor work; one reason being inability to procure, except at rare times, sand of sufficient grit and cleanliness to suit the work, and another and better reason is that there is much better material to be had for a little seeking. Sand is too globular in form to make good concrete, and by its use repeated failure will be the result. We recommend the use of riddings, though 4in. m. sh. of any hard grit which has passed through a stone-crusher, thus destroying all round arrises and making them sharp, and of good key to the cement; great care to be exercised in proper proportioning, and in mixing on boards by repeated turnings both dry and wet. It is utterly impossible that a good floor can be made on soft ground without any stone bottom. The cement, in all probability, has been good, but the sand probably has been very dirty, possibly loam or clay mixed in among it. Any kind of dirty matter tends to destroy cement. We should certainly say that the fault lies with the party who drew out the specification. He certainly seems not to know anything about concrete floors, and it also seems by "J. McD.'s" description as if the "clerk of works" had some animosity against the builder, who seems to have carried out the specification as well as it would allow him. The great mischief concerning concrete flooring is that persons are set to do this kind of work, and parties also make specifications of same who really know nothing whatever of the nature of the substances with which they are dealing. There is as much art to be used in laying a concrete floor as in any other trade, and it is an art very few persons are acquainted with. It is impossible to make a good concrete floor unless you have materials which are perfectly clean and hard, with sharp arrises to key, the best Portland cement obtainable, and a thorough knowledge of what you are about to do. This does not seem to have been the case in this instance. We certainly think the lay of the floors is not to blame.—ECCLES CONCRETE.

[6561].—**Disputed Contract.** Whoever employed the carpenter in the first instance has I consider little to complain of. He was, to judge by such an example as a "2in. concrete floor," incompetent. Second. Would any sensible person expect the carpenter to act fairly as clerk of the works after being defeated in tendering?—If he did, he would be more than human. The clerk of the works did not do his duty, if he permitted the work to be done wrongly and badly without strong protest. The opinion of "J. McD." that it is "unreasonable to hold the contractor responsible in the absence of a proper specification for a properly-made floor," and faults should have been remedied as they occurred "by removing the objectionable materials and works, or if the contractor became refractory, suspend the work till it was done" are correct. I consider the contractor cannot be made answerable for the floor or for the value of the materials used therein. Such a floor is bound to wear out speedily, even if executed with the best materials. To say that the Portland cement is to be of "best quality" is not enough for a specification. The other floor mentioned is not an instance, it had solid foundations. As to other matters, deductions can be made for lower walls or other omissions from plans or specifications unless a written authority can be produced or the alterations are not disputed.—HUGH McLACHLAN.

[6563].—**Smoky Chimney.**—If there is a blow-down, I should recommend "Down Draught" to use one of the cowls made by Byle and Sons, which prevent this. The plates are fixed horizontally, and the outer casing is made with sloped sides of > 90°, the effect of which is to cause a slight vacuum to be formed at the smoke outlet. One of these cowls would not cost much, and in all probability would answer the purpose. If there are any chimneys or buildings close which disturb the escape of smoke, simply lengthening of the pot will often effect a cure, as chimney-flues act as siphons, the short flues supplying air to rooms with the taller chimneys.—G. H. G.

[6564].—**Excavation.**—Each depth of 3ft. should be entered in separate items, owing to the increase of cost at the greater depth, the nature of soils should also be noted in bill. The rule given by "G. H. G." for the cubic contents is another and perhaps a simpler method than that usually given, which is, multiply the square of the diameter by 7854, and then by the depth.—HUGH McLACHLAN.

[6567].—**Bosses and Dogs.**—I believe bosses in plumber's work to be another name for solder dots, used for fastening lead cheeks to dormers, &c., and much fancied by some architects of the Queen Anne school. Have also seen the term used for the finishing or covering the ends of the wood rolls in laying flats, &c. I believe the term bossed joints is sometimes used for blown joints; if I am incorrect, some of the plumbing correspondents will perhaps rectify the error. "Dogs" is a term sometimes used for the hook irons let into the stone jambs of church and other doors to hang the hinges by

when no door-frames are used, they are generally divided into two branches with the ends turned down to catch in the stonework.—HUGH McLACHLAN.

[6568].—**Measuring Buildings.**—It is not necessary to have board and squares on the spot for plotting, though the plan is to be advised when great correctness of detail is wanted, and is often done for taking correct drawings of old buildings when competing for the medals given by the Royal Academy and the architectural societies. It is seldom done in measuring for alterations and additions to old buildings, as plotting on the spot though more exact requires more time. In measuring plans it is always necessary to have diagonals, though many avoid them if the rooms appear square. For correct work it is advisable to see that the plans can be divided into triangles where possible. For sections and elevations, heights only are generally necessary. Practice will help "Student" more than a column of letterpress.—HUGH McLACHLAN.

[6569].—**Measuring Buildings.**—I should advise "Student" to have a small drawing-board and square if he desires accuracy. A small square for testing the angles and a plumb-bob are useful and necessary in taking heights, the profile of eaves. For rough sketches, the dimensions may be taken in a dim-noson book, being careful to make the rough eye-sketch as nearly correct as possible, and to refer all minor dimensions to a baseline one side of the building, or to a centre line.—G. H. G.

[6568].—**Measuring Buildings.**—Set the dimensions of the building down accurately in your notebook; also by making a rough drawing on the spot, will, I think, be much better than carrying your board and squares about with you. You can then make a scale drawing of the building at home.—FRED. J. FREEMAN.

[6575].—**Parian Cement.**—I should recommend "Old Subscriber" to try one of the silicate paints—a light tint of colour could be applied. The Silicate Paint Co. and the Sanitary Paint Co. both supply paints for this purpose.—G. H. G.

[6577].—**Graphic Statics.**—I beg to inform "E.D." that one of the best elementary treatises I have seen is G. Sydenham Clarke's "Principles of Graphic Statics," published by E. and F. N. Spon, Chancery Cross. Another recent and more elaborate treatise on the subject is "Chalmers' Graphic Determination of Forces in Engineering Structures," published by Macmillan and Co. Both of these works have been noticed in the *Building News*.—G. H. G.

LEGAL INTELLIGENCE.

THE OLD ROMAN CAMP AT WALLINGFORD.—(Before Vice-Chancellor Hall.)—The Attorney-General v. the Corporation of Wallingford.—This was an action to restrain the Corporation of Wallingford from destroying an old Roman camp at Wallingford, which was used as a recreation ground, and was described as being an interesting relic of antiquity. The corporation appeared last Friday and submitted to a perpetual injunction upon terms which had been agreed to.

IN RE CHARLES BARTON.—The bankrupt, described as a builder, of Golborne-road, Westbourne-park, applied last week in the London Court of Bankruptcy for an order of discharge. The adjudication occurred in July, 1878, and at a meeting of creditors, recently held, a resolution was passed testifying that the failure had arisen from circumstances for which the bankrupt could not justly be held responsible. There was no opposition, and Mr. Registrar Pepys granted the order.

IN RE S. E. ADAMS.—The debtor, who recently presented a petition for liquidation, was a builder and slater carrying on business in Belvoir-road, Lordship-lane, his liabilities being returned at about £21,000 in the aggregate, with assets £23,500, subject to realisation. Mr. Marsden now applied, with the concurrence of creditors, for about £7,000, that Mr. Lucas, the receiver, should be also appointed manager of the estate, the object of the proposed appointment being the completion of pending contracts. Mr. Registrar Pepys granted the application.

IN RE W. SMEETON AND SONS.—The debtors, William Smeeton, John Smeeton, and William M. Smeeton, who have presented a petition for the liquidation of their affairs, are plumbers and sanitary engineers, carrying on business in Whitfield-street, Tottenham-court-road, and Moorgate-street, under the firm of W. Smeeton and Sons. Their liabilities are estimated at £20,000, with assets £3,250. Mr. Registrar Pepys on Tuesday appointed Mr. J. Cunliffe, accountant, receiver of the estate, and granted an injunction to restrain proceedings in several actions.

ALLEGED DEFECTIVE CONSTRUCTION OF A BUILDING IN HULL.—On Tuesday afternoon, Mr. J. J. Thorne, the Hull borough corner, held an inquiry into the circumstances attending the death of a child named Sarah Hannah Bowman, who was killed on the 4th inst. through the falling of a chimney at the manufactory of Messrs. Thacker, brick and tile manufacturers, Gibson-street, Hull. Mr. Thomas Thacker, a partner in the firm of Thacker and Co., produced the specifications and other documents for the erection of the chimney and other buildings. The plans were prepared by Mr. R. Wilkinson, architect and contractor, Newland, and the contract was signed by George

Sargent. Both men witness had known for years, and had confidence in them. The chimney, which was a little over 70ft. high, was erected about a foot and a half from the position indicated on the plans at witness's request to Sargent, so that more room might be obtained for an office. The concrete foundation had been in all the winter. It was stated by Mr. Wilkinson that the plans were altered several times, and that the foundations were laid according to one plan, and the chimney erected from another. One plan was prepared to suit the concrete which had been put in in the period which had elapsed since the previous plans were sent in.—Mr. Thacker's examination was resumed. He said that whilst the chimney was building his attention was called to the fact that it leaned. He told Sargent so, who said that he would see differently when the scaffolding was down, and that he knew how to build a chimney. The chimney was finished about nine days before it fell; but in the mean time he saw Sargent at Newland, and he asked him to get a big saw for the purpose of cutting some grooves into it to make it straight. Sargent had always insisted that it was plumb. The saw was not used. Witness took no means to ascertain whether or not the chimney was perpendicular, but left it to Sargent, who always asserted that it was correct.—By the Coroner: Sargent did not work at the chimney after it was 15ft. or 20ft. high. Witness had not heard of the architect complaining of the building. Had always been satisfied with Sargent's work before the building of the chimney, and if it had not fallen he should have been satisfied with the work. He did not recollect meeting Sargent and hearing him express his doubts as to the chimney being all right.—Mr. J. Baynes, borough analyst, deposed to analysing a sample of the mortar which had been used in the erection of the chimney. He thought it fair mortar. He did not find the mortar had adhered to the bricks, but that he could not account for it. It was more a question for a builder than for him to judge of. It was fair mortar, but he analysed a portion of the concrete foundation, than he should be rather inclined to speak of the cement as not being of good quality.—Other testimony having been adduced, the inquiry was adjourned.

NUISANCE FROM GASWORKS.—Among the cases which Mr. Justice Field had before him on Wednesday was that of "Bonner v. the Governors of Sutton Hospital." This was an action of nuisance. The plaintiffs are builders at Godalming, and had purchased some land on which they had erected some houses. The defendants, who are the authorities of Charterhouse School, are owners of some adjoining land, on which they had erected gasworks for the purpose of supplying the school buildings with gas. James Bonner, the plaintiff, stated that in 1869 he purchased the piece of land and built houses on it. One of the Charterhouse masters became tenant of one of them. Gas was first made in September, 1875. After the tenant in question left the house remained untenanted for twelve months. The smell from the gasworks was very bad. Mr. Collier, manager of the Godalming Bank, and estate agent, said that the property in question was put into his hands to let in March, 1880. He spent £15 in advertising. He was of opinion that the gasworks seriously depreciated the property. On cross-examination, he said there were two or three smells at the place in question, one arising from the drainage. Several other witnesses stated that they had observed a smell of gas. The manager of the Godalming Gasworks was one of the witnesses for the plaintiffs. Mr. Clarke, for the defendants, contended that the nuisance complained of had been greatly exaggerated, and called several witnesses in support of this view. These included Mr. Louis M. Stuart, the tenant of the plaintiff's house, who said that he took it first at £30 and afterwards at an increased rent of £45. On the average, there were 16 boys boarding in his house. He felt no inconvenience from the proximity of the gasworks. After some time the jury intimated that they had made up their minds that the gasworks were a nuisance; but the learned counsel for the defendants not agreeing that the verdict should pass against the governors alone, tendered as evidence a scheme for the regulation of Charterhouse School for the purpose of showing that the governors were bare trustees; also a statute passed to determine the constitution of the governing body under the Public Schools Act. The learned counsel for the plaintiffs then withdrew the case as against the governors, and judgment was given against Dr. Haig Brown, the head-master, the mode of assessing the damages to be settled by the learned Judge in case of difference between the counsel on both sides. Mr. Jeune then asked for costs on behalf of the governors, and the learned Judge, after argument, reserved the question.

The operative masons of Glasgow and the suburbs decided, on Wednesday week, to accept the employers' proposals and return to work on the conditions that the rate of wages shall be raised from 6d. to 6½d. after August 1st.

Our Office Table.

AN American correspondent writes:—"The best wash for covering walls, &c., that I have ever heard of is made as follows: For one barrel of colour wash—1½ bushel white lime, 3 pecks hydraulic cement, 10lb. umber, 10lb. ochre, 1lb. Venetian red, 1lb. lampblack. Slake the lime; cut the lampblack with vinegar; mix well together; add the cement, and fill the barrel with water. Let it stand twelve hours before using, and stir frequently while putting it on. This is not white, but of a light stone-colour, without the unpleasant glare of white. The colour may be changed by adding more or less of the colours named, or other colours. This wash covers well, needing only one coat, and is superior to anything known, excepting oil-paint. I have known a rough board barn washed with this to look well for five years, and even longer, without renewing. The cement hardens, but on a rough surface will not scale."

A RAILWAY tunnel through a volcano has been constructed, probably for the first time, in the southern island of New Zealand. Among the extensive volcanic phenomena of the island are the extinct volcanoes upon the Banks peninsula, east of the town of Christchurch. This peninsula, now only connected by bands of low and recent deposits with the mainland, was once a complete island, only formed by volcanoes which rose up from the bottom of the sea. The special construction of such an extinct volcano has been made visible by a tunnel of 2,620 metres length upon a railway between Christchurch and Littleton, which has pierced through the walls of a volcanic cone, and thus has laid bare its structure of successive streams of lava and beds of scorie, ashes, and tuffe, which are again intersected by dikes of younger volcanic rocks.

LAST week the Lord Mayor opened a Free Gallery of Fine Art for South London at the back of the free library, 143, Upper Kennington-lane. It is a loan exhibition, comprising works by Mr. C. B. Birch, A.R.A., Mr. E. B. Stephens, A.R.A., Mr. A. Elmore, R.A., Mr. G. F. Watts, R.A., Mr. T. Woolner, R.A., and Sir Frederick Leighton, P.R.A., who contributes three pictures. There are also interesting specimens of sculpture, including a group of marble busts lent by Sir John Bennett. In the centre is Mr. Gladstone, with Homer and Shakespeare on his right, and Gambetta and Oliver Cromwell on his left. Some fine examples of Wedgwood wares are also worthy of mention.

It is intended to open a museum of architectural, building, and sanitary appliances at Inverness, next month. Inverness, the capital of the Highlands, and the business centre of a very extensive district, is considerably removed from manufacturing towns, and the architects and builders have difficulty in bringing before their clients examples of articles specified or wanted. An exhibition, therefore, of such articles as are constantly wanted in the building and other allied trades cannot fail to prove beneficial alike to exhibitors and to the public. Central premises have been secured in the town, and will be properly fitted up for the reception of exhibits. The secretary is Mr. Daniel Warren, of 46, Union-street, Inverness.

DR. W. DOMETT-STONE gives the following directions for the preparation of chlorine, to which, of all the disinfectants at our command, most chemists give the preference:—Mix two table-spoonfuls of common salt, two tea-spoonfuls of red-lead, and half a wine-glassful of strong oil of vitriol in a quart of water. The bottle should be kept cool, tightly stopped, and in a dark place. A little of this fluid exposed in a saucer, sprinkled on the floor, or soaked in sheets of old linen and hung about the rooms, rapidly deodorises and destroys effluvia. In a paper published in the *Lancet* some years ago, Dr. Goolden spoke of this disinfectant as the most powerful and economical agent for eliminating sulphide of hydrogen from the atmosphere, as well as from all organic matter in a state of decomposition or putridity. He found it to be the most simple, the least expensive, and the most successful of all the disinfectants that had come under his notice.

THE death is announced of a prominent

Massachusetts architect, Mr. Alexander R. Esty, who died at his home in Framingham, July 2nd, aged fifty-four years. Mr. Esty received his early professional training in the office of the late Richard Bond, of Boston, and has practised in and about that city for many years, with eminent success. Among his principal works are the Union Congregational Church on the corner of Columbus-avenue and West Newton-street, the Harvard-street Baptist Church in Cambridge, Grace Church at Newton, Emmanuel Church, on Newbury-street, Boston, the new station of the Boston and Albany Railroad in Boston, the buildings of the Colby University, Waterville, Maine; the State Normal Schools at Framingham and Worcester, and the University of Rochester, N.Y. For the past five years he had been Superintendent of Construction to the new United States Building in Boston, and was a member of the special commission appointed by the President last winter to prepare a report in regard to the proposed Congressional Library at Washington.

THE United States Census Bureau has undertaken an important work in collecting information relating to quarries of building, flagging, ornamental, and other kinds of stone in all parts of the country. The inquiries cover not only the location and extent of the stone, but the amount of capital employed, the annual output, methods of quarrying and dressing, number of hands employed and wages paid, methods of transport and their cost, number of structures of all sorts made of each sort of stone, and so on. Duplicate samples of rough rock, in the shape of 4in. cubes, are being got from each quarry for physical and chemical examination. This part of the work is in charge of Dr. Hawes, and one object is to ascertain how each stone will act under different conditions as to temperature, &c. A stone which answers admirably for building purposes in Florida quite fails in New York, and *vice versa*. As an example of various interesting facts brought to light, some samples of rock (a kind of sandstone) were received from the only quarry in Florida, and analysis showed that the stone contained about 16 per cent. of phosphoric acid, so that it is a great deal more valuable as a fertiliser than as a building-stone. Sandstones and limestones which have never been thought worthy of any better place than in the foundation or wall of some rough structure, have been smoothed and polished, and found suitable for the most elaborate and elegant work. Dr. Hawes is convinced, from the samples already received, that no country is better supplied with stone for both building and ornamental purposes than the United States, and he considers that when the results of the present inquiry are fully known, importation of stone from foreign countries will be given up.

ANOTHER of the remaining churches in the City of London, which were erected after the Great Fire in 1666, will soon have passed away. The church of St. Mathew, Friday-street, is about to be demolished. It appears that the earliest record of the church, before its re-erection, is from 1322, when the patronage was vested in the Abbot of the Convent of Westminster: the establishment, however, was, in the language of the rescript, "dissolved," and Westminster created a Bishopric by Henry VIII., the living of St. Mathew's being conferred on the new diocesan. Subsequently it was bestowed by Edward VI. on the Bishop of London, who at the same time abolished the Bishopric of Westminster. After the fire above referred to, by which this church, as well as many others, was destroyed, the parish of St. Peter, Westcheap, was joined to it in 1685. The altar-piece and Communion-table, and other portions of the church, exhibit some noteworthy specimens of wood-carving.

THE United Kingdom Fisheries, Limited, is being formed for the purpose of supplying the public direct with fresh fish at all seasons of the year at a price much lower than that at present charged, and without the intervention of the middleman. The company have secured the business and services of Mr. Samuel Hewett, of Billingsgate Market, the well-known fish-salesman on commission, who has a large connection among consignors of fish, and has had many years' experience in every branch of the trade. The capital is £200,000, and the first issue £100,000 in shares of £1 each, payable 2s. 6d. on application and 7s. 6d. on allotment.

THE BUILDING NEWS.

LONDON, FRIDAY, AUGUST 5, 1881.

THE NATIONAL COMPETITION
DRAWINGS AT SOUTH KENSINGTON.

THE exhibition of prize drawings at South Kensington in connection with the National Competition is a fair yearly record of the progress made in the art schools of the United Kingdom. This year thirteen gold medals and fifty silver medals, besides a larger proportionate number of bronze medals and book prizes, have been awarded, in addition to the honorary awards to students in training-class, and national scholars at South Kensington. Edinburgh, Birmingham, Liverpool, Nottingham, Bradford, Coalbrookdale, Salisbury, and Dover are represented on the list of towns which take the gold medals this year, and scanning down the silver-medal list we find prizes awarded to students of Brighton, Southampton, Birkenhead, Barrow-in-Furness, Macclesfield, Cirencester, Kidderminster, Aberdeen, Sheffield, and a few other towns, in addition to those already mentioned. In the present notice we confine ourselves to the architectural and decorative designs and drawings. In these departments of art, Nottingham, Coalbrookdale, South Kensington, Salisbury, and Dover, carry away the highest honours, and other places deservedly rank high. The architectural work of the year is perhaps equal to that of any former period. Gothic design still occupies a prominent place in the schools, though several well-directed efforts in Late Domestic and Renaissance are to be noticed. We have had occasion before to remark the very ambitious kind of subjects set before students, and we must again repeat our objection to the florid types of architecture which students select, as calculated to lead to a mistaken view of architectural design. Why always select a cathedral for the principal gold-medal design? Might not a more ordinary kind of building, a town hall, a museum, or a library and art gallery exhibit the qualities required in the architecture of the present day more usefully? If architectural design is to be taught as a living useful branch of education, it might be better exercised in buildings of every-day requirements instead of in a cathedral, the object of which seems to be to teach the student the historic type and styles, though for this purpose measured drawings of old work would be more useful.

The architectural drawings this year are numerous, and perhaps rather above the average. The gold medal goes to Mr. Herbert G. Smith, of Nottingham, for a design for a cathedral. As we have said, the work is marked by that high-reaching kind of effort we have before discountenanced in these competitions. The design is florid to an excess, and the west elevation suffers from a crowding of gables and buttresses, despite its well-drawn and careful detail. What we most find fault with is the want of proportion and outline which generally characterise these ambitious attempts of students. Mr. Smith's design, clever as it is, is spoilt by an effort to condense as much drawing as possible in a certain compass, and the result is less effective on that account. A very spotty appearance is given to the drawing also, by the manner the stonework is hatched, and much loss of breadth is due to this cause. The plan is cruciform, with a central lofty tower and spire, and two west towers, also having spires.

There is a lady-chapel and library on the north side. The proportion of the plan is faulty, and the eastern and western arms have nearly the same length, six bays in the choir and seven in the nave. The flank elevation shows tall, narrow aisle windows elaborately traceried, and the lofty stilted proportion of this side is not agreeable. Nor can we admire the arrangement of the west and transept gables, with the elaborate rose-window under an inclosing arch; there is generally a cramped appearance in the bays, and the buttresses and pinnacles are crowded and lumpy in the towers. The east front is more successful, and the large, lofty Geometrical window has a dignified effect. The detail and tracery are firmly drawn, a sort of German character pervades the tracery, and much credit is due to the author for undertaking so laborious and difficult a subject.

Another gold medal has been awarded to Mr. Frederick W. Woodhouse, of South Kensington, for a series of designs for church-porches—a deservedly bestowed reward. Five drawings are sent. One shows a Late Perpendicular porch, covered externally with panelling, and having a stone roof, and an open-panelled stone drop-arch, dividing the porch into two bays. The elevations are well proportioned, though the details of capitals and base-mouldings are clumsy. Another sheet of three designs, in Early English, Geometrical, and Flowing Decorated, accompanies the set. Of these, the first two are the best; the latter has very heavy open-angle pinnacles, too large for the front. Sections are given which show pierced and traceried ribs beneath the stone roofs. The porches, from measurement by the same author, represent drawings of examples at Middleton Cheney, and St. Peter and St. Paul's, Chacombe, both in Northamptonshire. These are divided into bays, with stone divisional ribs or drop arches, and are interesting types. The porch of St. Mary's, Bloxam, Oxfordshire, is groined, and has a Norman inner doorway, enriched by zigzag; another at St. Andrew's, Sandon, Essex, shows a heavy brick porch with straight embattled parapet and large corner buttresses. Two open-timbered porches, one at Terling, Essex, Perpendicular in style, and the north porch of St. Margaret, Margaretting, in the same county, 15th century, show admirable examples. The details are carefully drawn.

A bronze medal goes to Mr. Hedley J. Price, Nottingham, for a design for cathedral. This work noticeably contrasts with the gold-medal design. It has a long-drawn nave and choir with Lady-chapel, the crossing being nearly central. A baptistery and chapel with apsidal ends are planned as a transept to the eastern part, and there are three towers. A commonplace Perpendicular treatment prevails, and the repetition of segment-pointed windows gives rather a stiff and hard effect to the details, which are also weak. We notice the flying buttresses are much too heavy for the pinnacles carrying them. A few other designs for a cathedral are hung which do not call for criticism; some of them are poor copies. A design for a church is the subject of some drawings. Mr. Alfred Williamson, Leeds, receives a book prize for a rather poorly proportioned design, but the alternative drawing for west doorway is well executed, and the details and section of roof are meritorious. A better design receives the same prize. The author is Mr. A. Hemingway, Barrow-in-Furness. The octagon and spire over crossing, and the west towers and gabled treatment, show some good points.

The same student wins a bronze medal for architectural details of St. Mary's Abbey at Barrow-in-Furness, illustrating the chapter-house, a building four bays in length and three wide. Another bronze medal is taken by

Mr. Alex. Pope, of the same town, for details of the Priory Church of St. Mary's, Cartmell, a Perpendicular structure with a peculiar central tower set diagonally. The carving to stalls is a good example. The drawings are boldly executed in line, and the Perpendicular window of nine lights is a feature. Mr. T. Smith, of Glasgow, receives a bronze medal for a design for an episcopal church. There is considerable boldness in the west-front, the lofty lancets and wide buttresses are broadly handled, and the tower and spire are well proportioned. A series of gables relieve the side. The drawings are in ink, but are rather poor. A bronze medal is won by Mr. W. Sydenham Richards, Cardiff, for a design for Colonial Houses of Parliament, a large and boldly drawn design, in French Gothic, with a lofty centre and flanking towers, the latter crowned by flat bulbous-shaped cupolas. The plan is quadrangular, disposed in a rather ambitious style. Mr. Richards is also the recipient of a book prize for a design for a picture-gallery and museum in the same style. We cannot commend the want of balance so conspicuous in the front elevation, where a central tower of some height rises between masses of building of very unequal heights and character. Both these designs we have seen before among those sent in for the Institute prizes. Merit there undoubtedly is, the stiff foliage-pinnacle-and-crochet style, if we may so designate it, has been ably carried out, with all the extravagances sanctioned by votaries of this type of eclectic Gothic; the drawing of detail has little in it to find fault with, though we cannot help regretting so much clever draughtsmanship has been expended on ideal architecture.

Domestic architecture is illustrated by a clever sketch design in pencil for a country mansion, in the Elizabethan style, by Mr. Frank Chester, West London, the plan of which is well conceived and grouped. The author takes a bronze medal. A similar reward is won by Mr. Haywood Rider, York, for a design of villa, in which red brick and half-timber work has been introduced with much feeling and good grouping in a Domestic style. It has a fairly-designed plan, and the drawings are neatly coloured.

Among other recipients of prizes for architectural drawings we may here mention a book reward is won by W. Morris, a student in the Training School at South Kensington, for an artist's residence in red brick, Renaissance in style, showing some good detail; and another to S. H. W. Llewellyn for two clever designs for public elementary schools in red brick and timber, effectively treated and coloured. The one-storied design is the best. This author is the winner of a silver medal for a chalk drawing. A bronze medal for a well-drawn elevation of an Italian residence goes to A. Whitehead, a training-school student, who exhibits an effective design, though the plan has many defects in it.

The drawings from measurement include a few carefully-tinted of a portion of the river-front of Greenwich Hospital. The silver medal is awarded to Fredk. W. White, a student in training class at South Kensington. The portion shown is the front of Charles II.'s building. The single order of Corinthian columns, with its lofty attic, are neatly drawn and shaded in sepia, if we overlook weakness in the detail. A bronze medal is given to the same subject, and J. Somerscales's drawing is equal, if not firmer, in the detail of the order and the mouldings. The three book-prize drawings also compete well for the honour, and the subject was a good one to exercise a student's knowledge of Classical orders and shading in monochrome. In another part of the room we see a few ink drawings of old work. G. F. Henny, Birmingham, takes a

bronze medal for some details of wood and ironwork from Aston Hall and other places. The chimney-piece and staircase are well drawn and tinted, and the ironwork details from Hampton Court are worth notice. J. Feek, Norwich, obtains a book prize for a measured drawing of oak screen, Elizabethan in date, curiously carved with pilasters.

We pass on to notice the designs for wall-decoration, and here a little more critical taste might be usefully exercised by those who have the management. Ornamentation is made apparently the measure of the ability of the student, and he who can crowd the most figures of graces, fountains, and scrolls in a given space, stands the best chance. The silver medal design by Thomas Smith, Coalbrookdale, for a side of a room in painted and majolica tiles, is worthy of the honour it obtains; the arabesques which form panels between pilasters exhibit some taste, and the colouring in a low key of browns and neutral greens is in good harmony. George W. Shepherd, of the same place, fairly obtains a silver medal for a design for music-hall decoration. The drawing takes the first prize of the Plasterers' Company. A rather weak pencil elevation, slightly shaded, shows the wall, divided by pilasters into panels, the latter having figures in the centre, with musical terms introduced in medallions in the dados of pilasters. The large scale drawing of panel is creditable; the figures in the centre and the scroll-work are well distributed, and the ornamentation, which is in Italian Renaissance, is refined. The frieze is broken by pediments, and there is a bold coving, but no section is shown, as there should have been. Another silver medal goes to the second prize of the Plasterers' Company by A. Hall, Cirencester, for the same subject—and here we regret the judges should have placed this design on an equal footing with the last-named, which is far its superior as a work of art. The panels are laden with coarsely-designed heavy scrolls, the centres having a group of ill-drawn figures representing the Three Graces. Vainly does the eye seek rest; dados, pilasters, frieze, and all are crowded with ornament, and of a kind devoid of all sense of gradation. The heavy scrolls in the panels overpower those in the dado below, instead of being lighter. The designs for mosaic floor are highly creditable to their authors. The silver medal drawing by James Thomas, of the Architectural Museum, Westminster, is well worthy of the distinction. The design shows a large circular panel in a semi-Greek or Byzantine style divided into radial compartments. The square border is filled with a guilloche pattern, and the colours are pleasingly combined. Much ability is shown in the coloured detail of one panel. The panelled arrangement with medallions, comprising emblematic figures by E. Jarratt, Coalbrookdale, receives also the same reward, and exhibits much merit, particularly in the colour arrangement. Meritorious also is the bronze-medal drawing by William Stevenson, Edinburgh, for a tessellated pavement designed in the style of ancient Celtic work, and the colouring is very quiet and pleasing, and we must not omit to refer to some excellent studies of designs for Italian mosaics, by James F. Mein, Kidderminster.

The designs for wrought-iron work show a few clever studies. The silver medal this year is won by Omar R. Albrow, Yarmouth, for a study of wrought-iron panels in which the material has been sensibly treated. The *motif* is a conventional adaptation of natural stems and leafage, with flowers here and there, and the author has succeeded in giving a freshness to the work. The bronze-medal gates, by Francis C. Jessop, Rotherham, is spoilt by an overcrowded effect, but the india-ink drawing is well executed.

John H. Marston, Great Yarmouth, also wins a bronze medal for a spirited and freely-treated design for gates, of more merit than the last; and Joseph Hope, Durham, sends a design (bronze medal) for the ironwork of a church-door, which has been freely treated, the scrollings filling up the pointed head of the door and the spaces between the hinges. The drawing is carefully outlined. Ernest Thickett, Sheffield, wins the same prize for wrought-iron gates, fairly treated; and a book prize is taken by McCulloch, Belfast, for a design in which the gate-piers of brick are connected by an iron archway and centre lamp, and with gates in which some pleasing upper panels appear. Another bronze medal has been awarded to W. B. Pratt, of the Training School, for a design spoilt by confused detail and over-elaboration, a fault from which most of the designs suffer.

Passing to the designs for wall-papers and textiles, the works hardly appear equal to those of former years in quality. The Owen Jones's competition has brought out a great deal of talent in one department, though none of the designs this time has been considered good enough to deserve the silver medal. Rose Phillips, Northampton, wins a bronze for a pleasing geometrical arrangement of leaves with flowers of rose tint on a grey ground, intended for a wall-paper. J. Clews, Nottingham, is also a winner in the same rank, the paper having a dark chocolate ground with bunches of yellow flowers. Of other bronze medal designs from Nottingham we note one by H. Williamson, in which the poppy flower has been introduced on a dark ground, exceedingly rich. Another, by E. Davies, in which the dark ground is covered with a leaf of the nasturtium order; also by A. Middleton, a black ground with leaves and flowers of a russet shade. Two other designs (book prizes) must be noticed, one by J. Jackson, Manchester, in which shades of green and pale foliage are pleasingly arranged, and the other by Rosa Carter, South Kensington, a delicate white flower on a grey ground naturally disposed. The designs for carpets are few. Salisbury this year wins the gold medal, the student's name being Gideon Fidler. An arrangement of leaves and flowers, thoroughly geometrical, in which shades of green predominate, is the characteristic of this design, and the author has produced a pattern eminently suited for textiles of this description. A kaleidoscopic regularity in the figures prevails. John H. Lamb, of Kidderminster, wins the silver medal for a clever adaptation of leafage. The ground is entirely covered and is of a dark colour, while the prevailing tints of the foliage are red, blue, and green. Mary Denley, Lambeth, also sustains her ability by winning a silver medal. The other prize drawings are creditable. Lucie Sheppard, Northampton, shows a conventional treatment of foliage, the colouring being good; a book prize goes to Janet M'Goun, Edinburgh, for some chaste wall-decoration. Octavia Liberty, Nottingham, receives a gold medal for a conventionalised Italian design for wall hanging, in which flowers and shields are introduced. The designs for lace are not equal to those of last year, and we find no remarkable pattern. Agnes Dickeson and Mary Joyce, Dover, are the winners of gold medals for designs for pillow-lace; and Margaret Douglas, Birkenhead, wins a silver medal for needlepoint lace borders, which show a want of clearness in the pattern. W. Bucknall, Nottingham, also secures a silver medal for a clever adaptation for a lace curtain; another design represents a handsome plastron of Honiton lace. L. Kirk receives a silver medal for lace-curtain design, and T. Dutton, A. Rowland, and Blanche Story, S. Birmenshaw and Meldrum do honour to Nottingham as winners of prizes. Designs

for muslins, are not numerous. G. Fidler, Salisbury, wins a bronze for a design for damask. Among other designs of a different class we may refer to some painted pottery, the best design of which is a chastely-painted plate, Persian in character, which receives a bronze medal, and another for a tazza. Alma Hodge, S. Kensington, and W. Nicholas, Coalbrookdale, and Edith Robinson, Bloomsbury, win bronzes. A few designs for fans, one a conventionalised landscape, are to be seen; and we notice designs for salt-cellar (J. Fisher, Sheffield), and for a silver candlestick (A. Winterbottom, of the same town), which have received silver medals; and J. Bradburn, Coalbrookdale, well known as a successful competitor in this class of design, this year receives the gold medal for design for a seven-branched candelabrum.

Drawings of ornament from casts are, as usual, numerous, and a few clever studies are to be noticed on the screens. The rewards here, as in some other classes, do not appear to have been bestowed purely on merit. C. Crane, Hull, has a book prize for a well-drawn monochrome study of frieze, and J. W. Elliott, Preston, for a monochrome in oil of flat ornament, creditably executed. Barbara Jackson, Preston, contributes a water-colour monochrome drawing of folial ornament. Silver medals in the same class are awarded to R. C. Daws, Bradford, for an ornament in monochrome from the cast, representing an acanthus leaf acroterium; to E. Marsden, Chesterfield, for a drawing in water-colour of a folial ornament; and to W. J. W. Stubbs, Bradford, for a Byzantine panel of sculptured foliage and birds. Several bronze medals are given to drawings from the cast in oil and water-colour, to which we may refer again.

We can only refer here briefly to those who have won distinction in oil and water-colours, reserving a more complete notice of them till next week. Of studies from the Antique in monochrome oil-colours, James C. Michie's work (Edinburgh) has been awarded the honour of a gold medal; and a similar distinction has been conferred on Robert E. Morrison, Liverpool, for a group in still life; on W. Breakspear, Birmingham, for an oil-painting of figure from the nude; and upon A. Hitchens, South Kensington, for a chalk-drawing from the nude model. Gold medals are also given to Mary H. Surene, Edinburgh, for a chalk-drawing from the antique; and to Frank Suddards, Bradford, for a group in water-colours. In the same classes, silver medals have been bestowed upon Thomas Alison, Edinburgh, for a monochrome-oil figure from the antique; Constance L. Anson, South Kensington, for a chalk study from life; Elizabeth Bark, Liverpool, for an oil group; W. Beeching, Brighton, for a chalk figure from the Antique; W. Busk, South Kensington, for the same; Mary E. Carter, Bloomsbury, for still-life group in water-colour; Thomas C. Castle, Birkenhead, for a water-monochrome of horse's head, from the Antique; Arthur Ellis, West London, a chalk drawing of head; John K. Fergusson, Edinburgh, for a chalk figure from Antique; Annie Hastling, Manchester, for oil-colour group; Rowland Holyoake, West London, chalk drawing from Antique; T. M'Keggie, Aberdeen, ditto; Samuel May, West London, oil-colour group; Margaret F. Moore, a water-colour ditto; Julia Mountford, Birmingham, monochrome in water-colour of head from antique; Ethel C. Nisbet, flowers in water-colour; E. L. Osman, South Kensington, chalk drawing of figure from the antique; A. Pearce, Lambeth, chalk study from nude; Constance Prince, Manchester, oil-colour group; Florence Reason, Bloomsbury, chalk drawing from antique; J. W. Stubbs, a monochrome in water-colour, and group in ditto; Ida

Taylor, Lambeth; Miss Wight, Kidderminster, monochrome in oil from antique; and A. Young, Edinburgh, chalk drawing. The bronze and book-prize drawings are too numerous to mention now, and to those and the merits of the chief drawings we hope to refer again.

BUILDERS' ARCHITECTURE.

STRAIGHT lines, red brick dressings, and tuck-pointed joints, seem to have a strange fascination for the speculative builder. The interminable rows of "neat suburban dwellings," varied here and there by "eligible villas," force the inquiry on the least inquiring mind, whether it is not possible to introduce a little more variety of shape and colour into our ever-growing suburbs. It is true there is not much room for invention in the planning and design of 6 or 10 room houses, confined to the limits of a narrow frontage, and builders are averse to adopt new plans, owing to the increased cost they sometimes entail. The stereotyped house in a row, with its conventional arrangement of entrance, passage, and stairs, its front and back parlours, and projecting offices in the rear, appears to be the nearest approach that can be made to economical house construction. It may be varied a little, but the extent of the variation is small, and the internal arrangement of the apartments remains much the same. The position of the front entrance is the chief consideration, and in a row of houses the doorway has to be placed somewhere in the front, either on one side or other of the principal apartment. There are two alternatives; one is to place them in pairs or group the entrances of the two adjacent houses, another to place them singly; and it must be confessed builders do not generally take much trouble about the matter, or do more than follow the common treatment, which makes a very insignificant feature of the entrance. Probably the most architectural manner of avoiding the isolated, disconnected look of our house doorways in narrow frontages, is to unite in some way the window with the entrance. This has been done in some houses we have seen by running the cornice-mouldings or entablature over the entrance, or by arcing the spaces left between the bay projections of the windows, and making a lead flat above. Both these plans can be treated architecturally if a little more time and patience be given to the working out of the problem.

Why there should not be more coherence between the bay-window and porch is not very manifest, seeing they are often quite close together on the same level. But the builder fancies somehow he must make a display of isolated features, and their connection would not make the most of his resources. So at least he thinks: it is for the architect to show how these every-day features can be rescued from their present stereotyped sameness. The objection to single doorways would disappear by an arrangement which united the entrances and bays in the manner we have mentioned. A plain flat wall from end to end of a street, pierced by windows and doors, or perhaps broken only by bay windows, has the most wearisome effect. Little or no effort is ever made to break up this long stretch of brick by any play in the line of frontage. If the bay windows are carried up two stories, and hipped back to the roof, there is at least a play of line, light and shadow, the flatness of the frontage is broken, and the eye less fatigued. The increased cost is very trifling, and the additional space thrown into the rooms is well purchased. Nearly all the houses we see have the roofs hidden, and their summits finished by straight parapets plain or pierced. Very seldom do we see the roofs honestly exposed, and the eaves

made to project, and throw off the water from the wall. Here again we see the object is to give a fictitious height to the house-fronts, to make them appear higher than they really are, and to give them an air of importance. Three or four feet is easily added to the elevation in this manner. But this expedient also pays the builder. The roofs being concealed, they can be constructed in the common centre-gutter fashion, so universal in London, with low pitch and a saving in timber. The front wall hides everything, and the abominable plan of laying a leaky gutter through the centre of bedroom ceiling is not even imagined by those who scan the almost palatial frontage of dwellings of this sort. The front wall becomes a mask which the builder finds pays him a good percentage as a return for the outlay. What we desire to point out is that the builder's front in virtue of its being a mask depends chiefly on its superficial ornamentation, which is never much deeper than the $\frac{1}{2}$ -brick reveal of windows and doors. An inspection of several estates shows what such ornamentation consists in. Colour is a cheap substitute for architectural relief and ornamentation; it captivates the vulgar taste, and we are not surprised to find it plays an important part in the speculative builder's *role*. Malm or stock brickwork looks very dull by itself, and a few stripes of red brickwork cost nothing and relieves the wall more effectively than solid relief or moulded work. This red brickwork is generally disposed of in the shape of cornices, arches, or simply neckings and dentils, though it is usual to find bands of it on the level of window-arches, or in courses of red brick lower down, suggesting a sort of appearance known by some as the "streaky-bacon style." The natural red-brick colour is not bright enough to relieve the London malm stock or "seconds" facing brick, and so they afterwards get rubbed over or coloured with red-ochre, as may be seen wherever new fronts are being finished, and as neatness in the jointing is another trap, the joints are "tuck pointed," a process which never covers the original joint. Very often the whole front is coloured yellow and tuck-pointed with lime-putty for the express purpose of making rough brickwork look respectable, though the brick-joint never covers the original properly and is constantly scaling off. The whole care is centred in making the mask perfect, and it is this trim neatness which takes the public unaware of the trickery and unreality of the building beneath this thin disguise. Why a little more boldness should not be attempted, and the straight front give place to a little more solid relief is chiefly to be answered by the disinclination builders of this class of property have to do anything fresh. A less glaring contrast of colour and more variety in plan and outline is easily secured by making the windows project, and by gabling them above; by setting the doorways back from the general line of frontage. There is much yet to do in prevailing on builders to adopt the gables and other devices found in the brick domestic architecture of Belgium and the Low Countries. Little is attempted in producing play of fronts, as we find it in the houses of Bruges or Amsterdam, chiefly from the fact that such breaks necessitate expensive guttering and more leadwork. By roofing with transverse ridges and gutters this difficulty can be avoided; and each house may be made to have its own gable without adding to the cost of the roof. A saving of brickwork in the party-walls would perhaps be rather overbalanced by the front and rear gables, but there would in return be more individuality in the design of street frontages. Much variety might be attained by even making a gable occur here and there in a long row, or in grouping them

together, if they are used throughout. The carried-up bay window is, as we have hinted, a step in the right direction, and a flat projecting bay is capable of being gabled in a variety of ways, without following closely the half-timbered and corbelled arrangements seen in houses of the Gothic or Queen Anne kind. If a projecting window is not desired, the cornice line can be broken by carrying up the head of the upper-floor windows and hiping or gabling the top, and the brickwork saved in thus allowing the front wall to be kept low, and the bedroom obtained partly in the roof, would more than repay the cost of valleys, extra flashings, and gutters.

All the suggestions we have made would, of course, make the roof a feature; but as this is the object the builder strives so much to hide from the gaze of the passer-by, very little reform can be expected till the roof becomes to be kindly looked upon as a feature rather than to be shown than kept out of sight. On artistic grounds alone, if nothing else could be pleaded, we might venture to recommend the tile roof. A very agreeable alteration would be evident if our long, wearisome streets of stock and red brick could show red-tile roofing above them, which would take off the glaring white fronts. The ribbed (Italian) tile, such as the Broomhall tile, or even the common pan-tile on a front of grey stocks, adds immensely to the appearance, and if there are any trees to be seen the artistic colour-sense is much gratified. A mass of red makes a more pleasing mixture of colour than a few streaks of it in the dressings, which latter are better shown by white Suffolks, or some darker shade of buff. Speaking of colour brings us to the question of the painted work. White soon gets dirty in towns, or there are reasons for advocating the clean, white window-frames and sash-panes of the Queen Anne; but why do builders persist in painting all the sashes black, or some colour which is made to assimilate in tone with the glass, and to make the eye believe the windows are in single sheets of plate? There is not a large choice of colours; but dark oak, or chocolate, without the graining, seems to be a far more sensible colour to paint the woodwork of doors and windows than black. The whole question of reform in our suburbs must rest mainly with builders. If they desire to follow in the wake of other art industries, they must aim at a higher standard of taste in ordinary house-building than we are accustomed to see, and must avail themselves of improved planning and elevations in the erection of dwellings which ought to represent something better than a multiplication of units in which human ingenuity, labour, and taste have been reduced to the lowest possible limits.

THE FURNITURE TRADES EXHIBITION.

AN exhibition was opened yesterday (Thursday) at the Agricultural Hall, Islington, in which furniture, decoration, and ironmongery are the leading branches of industry represented. From a general view of the stalls and the exhibits, still in a rather imperfect state, the Furniture Trades Exhibition is intended, apparently, to occupy the same ground in connection with these trades which the Building Exhibition did with reference to the particular industries connected with it. Furniture and decoration include a very large number of trades. Wood, metal-work, stained glass, wallpaper, textile fabrics, stoves, are a few of the materials displayed at the Agricultural Hall. As the catalogue was not prepared or published when our notes were made, we can only give the reader the result of a hurried visit to the exhibition when barely

half the objects were in place. The main body of hall is divided by avenues, and the principal exhibitors occupy stalls along the centre of these.

On entering, we find each side of the doorway set apart for the display of goods exhibited by Messrs. Wells and Co., of Shoreditch. On one side, brass-work and gas-fittings of every conceivable kind are displayed, and on the other we find furniture and decorative accessories in the furnishing trades represented. Messrs. Ashton and Green, St. Mary Axe, have a selection of chimney-pieces, in real and imitation marble in Italian and other styles, coal-vases, fire-irons of fashionable design, including "Queen Anne," beside-kitchens and the more useful kind of house-fittings. Messrs. Loder and Mr. Vaughan, of Old-street, are other exhibitors of furniture. Shutters and blinds are a class of manufacture in which considerable improvements have been made of late years, and those who wish to see what has been done to make the revolving shutter perfect may inspect the stall fitted up by Messrs. Clark, Bunnett, and Co. Besides revolving shutters, we see a smoke consuming fireplace, a double-box dinner-lift, to which we may refer again. Mr. T. Syer shows a folding ladder and other useful appliances. Mr. M. F. C. Turpin, of Queen's-road, Bayswater, has a variety of parquet floorings of simple and inexpensive patterns in oak, walnut, sycamore, &c., ranging in price from 1s. per square foot to 4s. The thin parquet, 5-16in. thick, is a very cheap substitute. Oak dados, chimney-pieces, and wood-carving are shown. Messrs. Drew and Cadman, High Holborn, have a handsome stall in which they show Venetian mirrors for walls and cabinets; and in a central position we find Messrs. Hodgkinson and Clarke, of Birmingham and Finsbury, have an artistically-designed stall in which specimens of their "Patent Metallic Venetian" blind is to be seen; also the "Queen Anne," a permanent shade for windows, combining the advantages of a blind, a revolving-shutter, and a ventilator. Stained-glass grills for windows, leaded windows, &c., are other objects. Mr. Geo. Sims, of Aldersgate-street, has a collection of overmantels, with bevelled mirrors, in ebonised wood and mahogany, after the Chippendale and Japanese styles. Several very effective specimens of wall-decoration are shown by the Papyrotile Company, Holborn. Some of these are in blue and black, in shades of green, gold and white, brown and gold, &c. The most critical taste could not fail to be pleased with a delicate blue Italian pattern on a gold ground embossed, and some friezes with festoon pattern and heads in delicate grey upon white ground. The panelled paper, highly relieved in gold and brown, with birds and foliage introduced, and one or two other specimens, may be admired also.

Messrs. Jackson and Graham occupy a central position in the hall, and their exhibits promise to be very complete. They chiefly comprise wall-decoration and suites of furniture for drawing-rooms, bedrooms, &c. We will merely mention here, a very tasteful decoration for a room in a quiet Chippendale style: walls of painted panelled work, showing a chimney-piece with stove, a mirror and neat overmantel finished in a light greyish green or apple-blossom tint. The effect is chiefly obtained by panels with sunk members in the framing and dentil mouldings in the doors and overmantel. The main relief consists in the flutings to the panels, &c., and in a deep frieze of painted tapestry. Ebonised cabinets with brass mounts, a very nice wardrobe with a middle shelf and splayed side doors with mirrors; a chimney-piece from a design by Mr. Edis, also a sideboard, and a dog-grate in black with brass mountings, are a few of

the other exhibits of this firm. The work is all machine-made.

Messrs. Carter and Aynsley, Bishopsgate-street Without, send a collection of ironmongery, brass-work, and ranges; Mr. W. Cluse, art-metal worker, of Tottenham Court-road, has also an exhibition in brass-work, including repoussé frames and mirrors, sconces, locks, cabinet furniture, &c., while near several specimens of wood, stained by "Stephens' preparations," are on view. Messrs. Pontifex and Wood have a large show of varnishes, stains, and colours; the Saxon Wood Industrial Co. exhibit their bent-wood furniture. One of the largest displays of chimney-pieces and decorative stoves is shown by Messrs. Steel and Garland; stoves with painted tile cheeks, in marble chimney-pieces, overmantels in ebony, walnut, &c., are on view. On the same side of the hall Messrs. Moore and Hulton have a large show of furniture, suitable for dining-rooms and bedrooms, entirely of oak, in a Gothic style; and Mr. Fox also is an exhibitor in the same class of goods. The very unfinished state of many large stalls preclude our mentioning them this week. Among our exhibitors we find the names of W. M. Owens, Shoreditch, cabinet manufacturers; G. Pearce and Co.; Bailey and Son; Ben, North, and Sons, West Wycombe; and Base Bros., ironmongers. The "Otto" gas-engine is one of the objects of a utilitarian kind to be found at one end of the hall, and at the other end we meet with a collection of pictures and frames, carved brackets, mouldings, chromo-lithographs, and other works exhibited by Messrs. Walmesley and Lewis. It will be seen from the above preliminary glance of the exhibition, that it appeals, not only to architects, but a large class of the public, and we hope next week to give a more detailed account of the exhibits.

THE WATER QUESTION.—XIII.

RESERVOIRS AND DAMS.

WHETHER the dry-weather flow of the drainage area should be deducted from the capacity of a reservoir found in the manner already stated, will depend upon the method by which the number of days' storage is arrived at; whether upon the basis of (1) the rainfall table, showing the absolute length of time during which no rain has fallen; or (2) upon the stream gaugings, showing the daily quantity reaching the site of the reservoir; or (3) upon the difference between two quantities, one of which is the quantity of water in an existing reservoir at the commencement of a drought, to which is to be added the quantity coming into the reservoir during the drought, whether from springs or casual rainfall—and the other quantity is that which has been discharged during the drought, as ascertained by the daily sinkings of the water-level of the reservoir, in which case it is evident that the total quantity is dealt with on either hand, and, therefore, no deduction can properly be made. But this method is true only of that reservoir, unless the dry-weather flow, where it is proposed to make a new one, is the same area for area; whereas by the other method the rule becomes general, and is applicable alike to cases where the dry-weather flow is large, comparatively, and where it is small. It is, therefore, better as a method, although the other is more exact for a particular case already existing. The dry-weather flow of the stream at the site of the reservoir is made up of the numerous small springs issuing within the drainage area, produced because of the absorbency of the ground during wet weather, and its yielding of the absorbed water gradually, and to this extent of the dry-weather production the drainage ground is essentially a part of the reservoir, and for this reason

the quantity should be deducted from what would otherwise be the necessary capacity. Were the ground wholly impermeable there would be no run of water in dry weather, and, in that case, the capacity of the reservoir itself would need to be so much larger; but where, as is assumed in the example, there is a dry-weather flow which, on the average, during a drought, is equal to 30 cubic feet per minute per 1,000 acres, that quantity may be deducted from the calculated storage-room in order to arrive at the actual capacity of the reservoir. The quantity so deducted belongs to the reservoir, and is, in fact, part of the yield reckoned upon in the available depth assumed, as, in the case adduced, 21in., and whether it be conducted past the reservoir and form part of the supply, or it run through the reservoir and form part of the discharge into the stream, makes no difference in the reservoir-room proper to be provided; but where the number of days' supply to be stored is founded on the length of a drought as ascertained from the rainfall returns the dry-weather flow ought to be deducted, and, instead of being deducted in gross, as in a preceding statement, the same result would be arrived at, if stated as follows:—

Quantity discharged from the reservoir—		208,800 c.ft. per day.
Deduct the dry-weather flow	} 43,200 " "	
= 30 c. ft. per minute		
Difference		165,600 " "

Then $165,600 \times 180 = 29,808,000$, or 30 million cubic feet as before, where the records of the rainfall show that 180 days' supply ought to be stored. Certainly, an eminent engineer might come forward and say "Shut up all your rainfall tables; I have the particulars of every reservoir in my pocket, and I can tell you exactly, by a little scale I have, the number of days to provide for. I will give it you. I do not put in these particulars, of course, because I want them myself; but you may depend upon the accuracy of what I say." This is all very well, and the engineer is fortunate who possesses all these particulars, and one is thankful for the information usually given to the public in evidence before Parliamentary Committees; but engineering evidence is often given confusedly because of the interruptions of members' questions before the witness has had time to unwind his clue and come to the gist of the question, which he can only do by proceeding step by step to what he desires to explain. Explanations of parts of his reasoning are given before their proper time and place, and the answers extracted by these inopportune questions are not exactly those he probably would otherwise have given. For instance, on a question of reservoir capacity, in explaining to what extent it is necessary to provide it, he is asked whether he includes the springs arising in the drainage-area, to which he answers, "Certainly not; they belong to the reservoir." Undoubtedly they do, and he would probably have explained at the proper time how they are to be accounted for, which can be in no other way than that above stated. So much for reservoir-capacity.

On a different basis altogether must be calculated the room required for temporarily holding a glut of water and allowing it to be discharged gradually; it must be upon (1) the depth of rain in a day, or in two consecutive days, or as long, in fact, as one rainstorm lasts—the exact time is immaterial; it is the glut of water as a whole which is to be provided for—and (2) the area over which it extends. Of such a depth we have records of four inches, but no measurements of the area covered by that depth. It is reasonably assumed, however, to be limited, and not to extend over the whole of a large watershed area. On the other hand, a less

depth of rain, one of two inches, for instance, extends occasionally over the whole of a river-basin, and produces in the lower lands even a greater flood than the greater depth over the smaller area; such was the case in the year 1875, when over nearly the whole of the Midland Counties of England that depth of rain fell in two or three days' time, and produced disastrous floods. But to confine attention to the upper lands, let the depth of four inches be reckoned upon as having actually fallen, and therefore to be provided for in the future; but over what area? One thousand acres = 1.5625 square miles, or about $1\frac{1}{2}$ miles long and one mile wide, or two miles long and three-quarters of a mile wide. These are considerable stretches of ground, over which a heavy rainfall may extend; but, not to underestimate difficulties, let the area be taken at 2,000 acres, which would be about 2 miles by $1\frac{1}{2}$ miles, or 3 miles long and 1 mile wide, or 4 miles long and $\frac{3}{4}$ mile wide, to be covered by the track of a great rainstorm, continuing for one or two days, and perhaps part of the third day, and amounting in the whole to a depth of 4in. over an area of 2,000 acres. If it be granted, as we think it ought to be, that this is a sufficient basis, we may proceed. The full 4in. in depth could not reach the dam in the time stated, or indeed in any time, for some of it must be evaporated. Let 3in. be taken as the depth over the whole 2,000 acres which would actually go into the reservoir or dam during the time of the rainstorm, or within no long time after its cessation, over and above the quantity discharged during the same time. On this basis, the space required for holding and moderating the flow off the ground of a great rainstorm in the upper part of a river basin, would be—

$$2000 \times 43560 \times .25 = 21,780,000 \text{ cubic feet.}$$

But to leave some water in the bottom, and otherwise to allow for contingencies, let this be increased to 24 million cubic feet, for regulating the flow of 3in. depth of water running off an area of 2,000 acres. More than 3in. out of a rainfall of 4in. may reach the reservoir, or dam, but it will not do so before the discharge has reduced the level sufficiently to receive it; and it may be reckoned as pretty certain that no second rainstorm will succeed one of 4in. until long after that one has been discharged by the river. It is one of the difficulties of the situation that in any river-basin the rainstorm may take place anywhere, although some parts of a large area are more subject to rainstorms than others. It seems inevitable, therefore, that works for this purpose must be numerous, but in that case the magnitude of each need not be great. In the instance above adduced, it is 12,000 cubic feet per acre of the drainage area, if the area does not exceed 2,000 acres.

So much for the capacity of a separate dam to regulate the flow off the ground of excessive rainfalls; but this and the other purpose—viz., a supply of water—may both be accomplished on the same site by the construction of one reservoir only if the demand for water in any particular situation does not prohibit it. In that case it will be a question of favourableness or otherwise of the various reservoir sites whether for any desired capacity of storage there should be one or both constructions, and if one is desirable its two functions may be performed by providing on the top of an ordinary reservoir a space equal to 12,000 cubic feet per acre of the drainage-ground if it does not exceed about 2,000 acres; and where the area appropriated exceeds that area, to provide 24 million cubic feet of reservoir room in addition to the capacity required for the ordinary reservoir. From the ordinary reservoir the water would be discharged from the bottom or below its top-water level, and from the upper space, or

regulating reservoir, it would be discharged at the top-water level of the ordinary reservoir through an opening which would discharge a given maximum quantity per minute, whatever height the water may rise to, so that in regularity of discharge it would act automatically. As the surface of the water in the ordinary portion of the reservoir will vary in altitude below a standard height, a heavy rainstorm may amount to no greater quantity than will fill it up to its standard height, but when this portion is full, or nearly so, the water of a heavy rainstorm will rise into its own space and be discharged by its own outlet.

The times when it is most important to prevent rivers overflowing are in summer, or between May and October inclusive; a winter flood is less, if at all, objectionable upon the land; and it is during those months that the greatest demand for water takes place. The winter rains fill up the reservoir to its standard height, but no higher, because the water at that height runs away automatically, and it begins to lower as summer approaches, making so much more room for an excessive flood, but this room is not reckoned upon in the foregoing calculations, so that they are all the more ample.

To take an example of a dam in the upper part of a river-basin, constructed solely for the purpose of moderating the flow off the ground of an excessive flood, such as 3in. in depth of water out of a total fall of 4in., and extending over 2,000 acres of ground, the room required would be, as before said, 24 million cubic feet. This would be found at one of the sites formerly referred to with a bank about 35ft. high, the greatest depth of water being 30ft., and covering about 37 acres of ground; or it would be found at one of the other sites with a bank 43ft. high, the greatest depth of water being 35ft., and covering an area of about 29 acres. In this case it is assumed that the rainstorm covers the whole drainage area, and then the size of the dam is at the rate of 12,000 cubic feet per acre.

To recur to a point incidentally mentioned above; that, namely, of the source, or one of the sources, from which we derive information on the question of sufficiency, or otherwise, of a stated number of days' supply—of the quantity of water resulting from the dry-weather flow of streams, &c.—viz., the evidence of eminent engineers given before Parliamentary committees—is it legitimate information? Are we entitled to make use of it in this or any similar manner for public instruction—or, to put it on the lowest ground—for our own profit? Is such information, given to a Parliamentary committee, given to the public? It is not, as it happens in this case, our only source of information; but it might have been, and so far as we have made use of the Parliamentary blue-books or notes of evidence taken at the time of delivery, and if we owe any apology to witnesses, our acknowledgments are due to Mr. Bateman and to Mr. Hawksley, who will, no doubt, notwithstanding, allow that we may agree or differ in a matter of opinion on any point in question. Indeed, we may anticipate an answer to all our queries, to the effect that we may take the information for what it is worth, and be welcome.

But the matter does not rest there. The evidence is valuable chiefly for the facts stated, facts which only they, pre-eminently, have had the opportunity of acquiring. It is not long since Mr. Bateman said casually that he was then making a dozen or twenty reservoirs, and we know that Mr. Hawksley has also had vast experience in waterworks practice, and that the archives of either of them must be a wealthy store of facts. We say again that these facts ought to have been ascertained at the public expense, so that engineers in general might found upon

them such opinions and arrive at such conclusions as they might be able to arrive at. But valuable as these archives would be, if national property, there are many facts yet to be ascertained, compared with which these would only be a beginning.

DANGERS TO HEALTH.*

THE idea of imparting in a popular manner, by means of pictorial aid, a knowledge of the dangers arising from drains and waste-pipes and other domestic fittings of our houses has been happily carried out by Mr. T. Pidgin Teale, M.A., surgeon to the General Infirmary at Leeds. The small octavo volume we have under notice is dedicated to the medical profession, and has passed through two editions in a short time—the best evidence that such a work has been found to answer its purpose. In the present edition we find the number of plates has been increased from 55 to 70, and these represent pretty completely the main typical defects or dangers to which our houses are exposed. The object of the author is to show by ocular demonstration, by clearly-printed illustrations—and these are forcibly-drawn lithographic diagrams—the sundry dangers to which every dweller, especially in our towns, is exposed. Each illustration is made to point to a defect, and the series are arranged in a scientific order, beginning with faults of a common and ordinary kind, and proceeding to those of a less direct, more rare, and complex character. In addition to these the author exposes many of the "rascalities" of the dishonest builder, and illustrates a few hints on ventilation, &c. Many of the faults thus pictorially brought before the eye are within the tenant's power to remedy; and the main object of Mr. Teale has been to educate the public in the details of domestic sanitation. The leading points in each diagram are represented in thick lines, while blue arrows in all cases show the direction of the escape of sewer-gas. Some of the sketches have been contributed by Mr. C. R. Chorley, architect, of Leeds, and the plumbing details have been supervised by Mr. R. Slater, sanitary inspector. A list of sanitary maxims introduce the reader to the illustrations.

Let us take a few of the cases represented. Passing over a few of the commoner kinds of defects, which are too obvious to require condemnation, such as closets in the centre of house, drains under floor leaking and pervious to gases, fires fed by impure air coming through doors and crevices, we come to the very frequent case of a trapless waste-pipe of sink emptying direct into drain, and the fault corrected by cutting off the waste-pipe and allowing it to discharge into a trapped gully. Next is an illustration showing the waste-pipe of sink entering the soil-pipe of closet; and the frequent occurrence of lavatory and bath-wastes entering direct into soil-pipe without traps, and their remedies; also the phenomenon of "unsiphoning" traps. The evaporation from traps below the "seal" is explained by another diagram, which shows the escape of gas into the house through w.c.'s and lavatories, cisterns, &c. Plate 10 shows a common error of making the overflow from a lavatory join the waste-pipe below trap, thus rendering the safeguard of the latter useless; and the following illustration instances a case where the untrapped lavatory-waste in a dressing-room caused puerperal fever, by allowing escape of sewer-air into a bedroom. Another plate shows the condition of a lavatory-waste, although trapped, allowing the passage of gas from closet-pipe, with which it was connected. Other diagrams show overflows from kitchen-boiler fouling water of boiler; rainfall-pipes, carried through the house, and giving vent to gases at the joints; untrapped wastes entering fall-pipe; rainfall-pipes, connected with sewer, opening below windows; ventilating pipes connected with chimneys; the inroads made by rats under floors through imperfectly-jointed sink-waste; defective water-closet arrangements, with soil-pipes within the house, and direct communication between it and cistern by the overflow. The author shows by diagram the abomination of the "pan-closet," which is called the "utterly utter abomination," and the advantage of the siphon basin and disconnector.

* Dangers to Health: a Pictorial Guide to Sanitary Defects. By T. PIDGIN TEALE, M.A. 2nd Edition. London: J. and A. Churchill, New Burlington-street.

tion. The injuries to health inflicted by lead soil-pipes, with seamed joints, and eroded by gas; by untrapped drains leading to larder, or sunk or dish-stone; dairy sweepings; soft-water eastern below floor used for cesspools; the dangers from overflows from storage tanks, cess-pools leaking into live wells, and other forms showing how people drink sewage, are equally well and cleverly pointed out. Such illustrations as Plates XXXI., showing badly-joined drain-pipes leaking into well, and plate XXXIV. will make very clear to the dullest comprehension how sewage may pollute well-water. Leaking drains under houses, broken pipes, bad laying, putty-joints, and various other causes of mischief are pointed out with suggestions for remedies, as to which we may have something more to say. Even refuse-heaps, ash-pit refuse for mortar, arsenical wall-papers, are made the subject of pictorial teaching. A chapter or two on ventilation without dirt is added, and the author's plan is at least simple. It consists, in fact, of a flat tube like Tobin's, and a screen placed diagonally from top to bottom to act like a filter. The Floral art ventilator, made by Messrs. Howell and James, is also well spoken of. We may add that many of the defects exhibited have their remedies pointed out, and this edition contains a number of newly-discovered faults, such as soil-pipes ventilated into false roofs, and other accidental causes of evil. The errors pointed out are not hypothetical: most of them have actually occurred in the author's own experience, which fact gives much weight to the knowledge which has been so pleasantly imparted. We think Mr. Teale's book ought not only to be placed in the hands of every householder and lodger, but should also form one of the text-books in our schools.

PRACTICAL NOTES ON PLUMBING.*

VIII.

By P. J. DAVIES, H.M.A.S.P., &c.

TINNING IRON PIPES, COPPER OR BRASS-WORK, BITS, &c.

IN chapter II. I described the method of tinning the bit, &c., with resin; but before this work on Joints can be considered complete, I find it necessary to speak of tinning the ends of iron pipes, &c., which have within the last 50 years been much used in conjunction with leaden pipes. This is done as follows: Take some spirits of salts (otherwise known as hydrochloric acid, muriatic acid, hydrogen chloride, HCl), in a gallipot, and put as much sheet-zinc in it as the spirit will dissolve: you have then obtained chloride of zinc (ZnCl). A little care is required when making this, as the acid is decomposed and is spread about by the discharged hydrogen, and will rust anything made of iron or steel, such as tools, &c. It also readily absorbs ammoniacal gas, so that, in fact, sal-ammoniac may also be dissolved in it, or sal-ammoniac dissolved in water will answer the purpose of the chloride of zinc.

Having the killed spirits, as it is sometimes called, ready, file the end of your iron or bit and plunge this part into the spirits, then touch your dipped end with some fine solder and dip it again and again into the spirits until you have a good tinned face upon your iron, &c.; next you require a spirit-brush.

SPIRIT-BRUSH.

You can make this by cutting a few bristles out of a broom or brush, push them into a short piece of compo tube, say, $\frac{1}{2}$ in., and hammer up the end to hold the bristles; next cut the ends of the bristles to about $\frac{1}{4}$ in. long, and the brush is ready for use.

SOLDERING IRON TO LEAD.

Suppose you want to make a joint round a lead and iron pipe. First file the end of your iron pipe as far up as you would shave it if it were lead, and be sure to file it quite bright and free from grease; heat your soldering-iron; then, with your spirit-brush, paint the prepared end of your iron, and with your bit, rub over the pipe plenty of solder, until the pipe is properly tinned, not forgetting to use plenty of spirits; this done, you can put your joint together, and wipe in the usual manner. Caution.—Do not put too much heat on your iron pipe,

either when tinning or making the joint, or the solder will not take or stand.

DUMMIES FOR PIPE-BENDING.

Figs. 38 and 38b. This tool I had better describe before proceeding to the method of bending. To make it take a piece of, say, $\frac{1}{2}$ in.

iron pipe, 3ft. long, or the length required, bent a little at one end, as shown at A B in Fig. 38, and Fig. 38b. Tin the end about 2in. up, make a hole with a small plumbing-iron in some sand, and place the tinned end of the iron pipe B into this hole; fill the hole up with good hot lead, and the dummy, after it has been rasped up a little, is ready for use. It will be found handy to have three or four different lengths, and bent to different angles, to suit your work. A straight one (Fig. 38b) made to screw into an iron socket or length of gas-pipe, will be found very handy for getting dents out of long lengths of soil-pipe.

BENDS AND SET-OFFS.

Before you begin bending solid pressed pipes always put the thickest part of your pipe at the back. Lead, in a good plumber's hands, may be twisted into every conceivable shape; but, as in all other trades, there is a right and a wrong way of doing everything, and there are many different methods, each having a right and wrong way, which I shall describe. I shall be pleased if my readers will adopt the style most suitable for their particular kind of work; of course I shall say which is the best for the class of work required.

For small pipes, such as from $\frac{1}{2}$ in. to 1 in. "stout pipe," you may pull them round without trouble or danger; but for larger sizes, say, from 1 $\frac{1}{2}$ in. to 2 in., some little care is necessary, even in stout pipes.

Fig. 37 illustrates a badly-made bend, and also shows how it comes together at the throat

FIG 37

X and back E; L is the enlarged section of X E, looking at the pipe endways. The cause of this contraction is pulling the bend too quickly, and too much at a time, without dressing in the sides at B B as follows: After you have pulled the pipe round until it just begins to flatten, take a soft dresser, or a piece of soft wood, and a hammer, and turn the pipe on its side as at Fig. 37; then strike the bulged part of the pipe from X B towards E, until it appears round like Section K. Now pull your pipe round again as before, and keep working it until finished. If you find that it becomes smaller at the bend,

take a long bolt and work the throat part out until you have it as required.

BENDING WITH WATER (LIGHT PIPES).

Fig. 39. This style of bending is much in

use abroad, but not much practised in London, though a splendid method of work.

It is a well known fact that, practically speaking, for such work, water is incompressible, but may be turned and twisted about to any shape, provided it is inclosed in a solid case—Fig. 39 is that case. The end A is stopped, and the stopcock B soldered into the other end. Now fill up this pipe quite full with warm water and shut the cock, take the end A and pull round the pipe, at the same time dressing the molecules of lead from the throat C towards D E, which will flow if properly worked.

You can hammer away as much as you please, but be quick about it, so that the water does not cool down, thereby contracting; in fact, you should open the cock now and then, and recharge it to make sure of this.

SAND BENDING.

This is a very old method of bending lead-pipes, and answers every purpose for long, easy bends. Proceed in this way: The length of the pipe to be 5ft., fill and well ram this pipe solid with sand 2ft. up, then have ready a metal-pot of very hot sand to fill the pipe one foot up, next fill the pipe up with more cold sand, ramming it as firmly as possible, stop the end and work it round as you did the water bend, but do not strike it too hard in one place, or you will find it give way and require to be dummied out again, or if you cannot get the dent out with the dummy send a ball through (see Bending with Balls).

BENDING WITH BALLS OR BOBBINS.

This style of work is much practised on small pipes, such as 2in. to 3in., especially by London plumbers. Method: Suppose your pipe to be 2in., then you require your ball or bobbin about 1-16in. less than the pipe, so that it will run through the pipe freely. Now pull the pipe round until it just begins to flatten, as at Fig. 37, put the ball into the pipe, and with some short pieces of wood (say, 2in. long by 1 $\frac{1}{2}$ in. diameter) force the ball through the dented part

FIG. 40

of the pipe, or you may use several different-sized balls, as at A B C, Fig. 40, and ram them

through the pipe with a short mandril, as at D M. You will require to proceed very carefully about this ramming, or otherwise you will most likely drive the bobbins through the back at L K J. You must also watch the throat part G H I, to keep it from kinking or buckling-up; dress this part from the throat towards the back, in order to get rid of the surplus in the throat.

THREE-BALL OR LEAD DRIVING-BALL AND DOUBLE-BALL BENDING.

Fig. 41 shows a method of bending with three balls, one of lead being used as a driver attached

to a piece of twine. This is a country method, and very good, because the two balls are kept constantly to the work. First, put the two balls just where you require the bend, then pull the pipe slightly round; take the leaden ball and drop it on the ball B, then turn the pipe the other end up and drop it on A, and do so until your bend is the required shape. You must be careful not to let your leaden ball touch the back of the pipe. Some use a piece of smaller leaden pipe run full of lead for the ball C, and I do not think it at all a bad method, as you can get a much greater weight for giving the desired blow to your boxwood balls.

BENDING WITH WINDLASS AND BRASS BALL.

This is an excellent method of bending small pipes. Fig. 42 will almost describe itself. A is

a brass or gunmetal ball having a copper or wire rope running through it, and pulled through the flattened part of the pipe as shown. It will be quite as well to tack the bend down to the bench, as at B, when pulling the ball through; well dress the lead from front to back to thicken the back. I have seen some plumbers put an extra thickness of lead on the back before beginning to bend. Notice: nearly all solid pressed pipes are thicker on one side than the other (as before remarked), always place the thickest part at the back.

HYDRAULIC OR CUP-LEATHER AND BALL BENDING.

Fig. 43. This is my own method of pipe-bending, and is very useful when properly handled with plenty of force, but requires great care and practice. You must have a union

sweated on the end A, Fig. 43, and the ball B to fit the pipe. The cup-leather E should have

a plate fixed on the front to press the ball forward. Pull up the pipe as you please, and pump the ball through, it will take all the dents out, and that too very quickly.

(To be continued.)

THE SCIENCE AND ART OF SANITARY PLUMBING.—VI.

MR. HELLYER'S sixth lecture was delivered on Thursday, July 28th and repeated on Friday 29th. Professor H. Robinson, of King's College, presided, and announced that Monday, August 15th, had been fixed for the discussion of Mr. Hellyer's lectures.

The lecturer commenced by observing that in this lecture he should treat of the connection of branch-pipes with main pipes and traps; waste or overflow pipes from safes; cistern wastes; disconnection of drains from sewers and cess-pools; drain ventilation; and the value of good water flushing. All branches, whether for conveying dirty water, soil, or sewage, should be connected to their main-pipes in such a way that the discharges through them shall pass into the main pipe in the direction of its outfall, and in such a manner as not to foul any part of the pipe, be it a waste-pipe, soil-pipe, or drain, where it would not be cleansed by the flush of water following such discharges. In fixing a range of water-closets on a floor, the branches from them were often made to enter the chief branch on its upper side, and in such a manner

to continue on the chief branch-pipe for ventilation above the highest of the minor branches, for the discharges from the latter would splash and flow up towards the open end of the chief branch-pipe, especially if more than one water-closet was discharged at one time, and as there would be no water-traffic through that part of the main branch, it would not only become foul, but would be liable to stoppage,—at any rate, sufficiently so to prevent proper ventilation. No ventilating-pipe should be taken from a waste-pipe, soil-pipe, or drain, at a point which could be closed up by a stoppage or back-flow in the pipe,—i.e., the ventilating-pipe should always be connected to the waste-pipe, soil-pipe, or drain in such a way as to make it difficult for discharges sent through such pipings to reach the mouth of the ventilating-pipe to choke it, and the connection should be so made that if anything splashed up into the ventilating-pipe it should readily fall back, or drain itself out again. How often did one see a range of lavatory basins fitted up with the branch wastes from them entering the top of the main-branch at right angles! When a basin near the main waste in such an arrangement was emptied through a minor branch into the main branch the contents of the basin would flow both ways, and the suds would hang about the pipe and corrode upon it unless the basin farthest from the main waste were immediately used. Another evil attending such an arrangement was that there would be a constant circulation of the vitiated air in the main branch from basin to basin, and such bad air, arising from stale soap-suds and other matter adhering to the sides of the pipe, would be breathed by the persons bending over the basins to wash their hands; for in the "tip-up" basins the impure air would easily come up between the basin and the "receiver," and in plug-basins (though the plug might be in its place) the air would easily escape through the overflow arm. Another error often made in the arrangement of lavatory wastes, where a range of basins discharged into one trap, was in taking the main branch into the heel of the trap in such a way that about two-thirds of the length of the main branch was always full of water. When that was the case, how was it possible to change the "standing water" of the trap and the waste-pipe with a flush of water sent through either of the basins? The body of water standing in the trap and piping might become very offensive from the use of scented soap and the washing-down of the lavatory top, and it would prevent the waste-pipe from being cleansed, for no flush of water could be sent through the pipe with any cleansing force. When a waste-pipe from one "fitting" was branched into the trap fixed under another fitting, the connection should be so made that no air could travel from one fitting to the other, as it easily could under arrangements sometimes adopted. If one trap must be made to receive the waste-pipes from more than one basin, sink, bath, or urinal, when fixed adjoining each other, the ends of such pipes should be taken into the trap under the normal level of the standing water. But, even that arrangement, though it might do for certain places, was imperfect in principle and faulty in detail, and therefore should never be carried out in fixing sanitary fittings near a living-room or bedroom. In dressing-rooms it was common to find the lavatory-waste connected with the bath-waste, but it was impossible to keep such arrangements absolutely sweet. When two or more waste-pipes discharge into one trap, with their ends under the water-line, the filth carried down one pipe floated up into one or more of the other pipes, and collected and lodged there. Though the matter sent up in that way might only be small in one usage, it became large from repeated usage. The lavatory would most likely be in constant use, but the bath might not be used more than two or three times a week, and when used the discharges from it would not wash out the dried filth, for that would have collected upon the sides of the dip, and of the bath-waste, above the discharging orifice. Besides, in such arrangements, a large trap was often used, with small branch-wastes into it from the adjoining fittings, so that the trap could not get properly cleaned out by a flush of water sent into it through such pipes. In such cases, filth collected very quickly in the dip or inlet part of the trap. When, on the other hand, each fitting had its own trap, the water flushes through it could be made to cleanse every part of it, provided that

the water-way from the fitting into the trap was of the same bore, and that the trap was of a self-cleansing form—i.e., a round-pipe trap.

It was still the practice with many country plumbers, where they fixed safes under water-closets, to connect the waste-pipe of the safe with the water-closet trap, and to fix the pipe of too small a size to be of any value in any great overflow of the water-closet. But, supposing the pipe to be large enough to take away any overflow from the closet or leaky supply valve, its connection with the trap of the water-closet, where the stoppage which had caused the overflow had occurred, would prevent the water getting away, and the safe would be of no good in preventing the water from overflowing and doing damage. But the chief evil in such an arrangement was that excremental matter would flow up into the safe and waste-pipe from time to time, fouling the pipe where it would have no chance of being cleaned out again, and every usage of the closet would cause a disturbance of the water standing in the pipe, and make it smell. The evil was much aggravated when the pipe was connected to the cheek or heel of the water-closet trap with its orifice partly above the level of the standing water, for soil-pipe air would then readily escape through the waste-pipe of the safe into the house. The system of fixing a separate trap under the safe, and taking the waste-pipe from it into the soil-pipe, was radically wrong, though it might, with a "weeping" pipe to charge it, be an improvement on the method last mentioned. But, in a tier of water-closets, such traps often got siphoned, and then they became inlets for bad air to the house, and might continue for hours, and even days, unsealed, and all the time the air from the soil-pipe would be escaping into the house, for the water-closet with which they were connected might not be used for days together to recharge them. The only safe way of fixing safe-wastes was to connect a 2in. or 1½in. lead waste-pipe to the safe, and carry it through the external wall, leaving its end open for ventilation, except where birds were likely to build in it, or where the frosty air could blow through it to freeze the service-pipe to the water-closet or the water-closet itself. There was very little fear of that when the ends of such pipes faced the south, and when the service-pipes were protected; but where the ends of overflow-pipes were open to the north or north-east, the air whistled up the pipe and froze the basin water,—perhaps breaking the basin and bursting the pipe. It was, therefore, better to solder a brass or copper-binged flap on the ends of such pipes to shut out the frost and to prevent birds building in them. When, however, such pipes could be left open, they helped to change the air in the room, with a few perforations in the water-closet seat. Of course, where that was done, the space between the top of the basin, and the seat must be packed with india-rubber to prevent any draught coming to the occupant; and when there was any frost in the air, a piece of board could be placed over the mouth of the overflow-pipe, but that needed personal attention. The mouth of the overflow-pipe should be enlarged and soldered to the safe, and the "outlet" end should be kept at least a foot below the level of the safe, so that the weight of the overflowing water might well open the hinged flap where the latter was used. Overflow-pipes to safes under baths or slate or galvanised-iron cisterns should be treated in the same way as overflow-pipes to water-closet safes,—i.e., a pipe of sufficient size to take off the supply of water to such fittings should be fixed to the safe, and carried through the external wall to discharge, with an open end outside; and, to prevent such pipes becoming inlets to the house for bad air, the ends should be kept well away from all ventilating-pipes to waste-pipes and drains, and from places where any bad air could reach them. Where stop-cocks were used for supplying a bath with water, or where any supply-valve by leaking dropped its water into a safe, provision should be made in the connection of the bath-waste with the safe for taking off such leakage, for if it were allowed to run down the overflow-pipe in frosty weather, the word "safe" would be a misnomer, for the dripping water would freeze up the outlet of the overflow-pipe, and then, if an overflow took place, it would soon flow over the safe on to the ceiling.

Waste-pipes from cisterns should never be connected with any other kind of pipe. As de-

scribed for overflow-pipes from cisterns, waste or overflow-pipes from cisterns should discharge into the open air, well away from all places where any impure air could reach them, for when they discharged over a gully or any other drain-trap, they acted as air-pipes from such traps. Any drain-air passing through the trap (caused by the water in the trap having evaporated, or by the disturbing action of discharges into the trap) would pass through the waste or overflow pipe to the water in the cistern, and contaminate it. It was also a great evil to discharge a waste or overflow-pipe from a cistern into a rainwater-pipe with which might be connected a sink or lavatory waste, for such rainwater-pipe was sure in time to become foul, and the bad air arising from it would readily escape through the cistern-waste to the water in the cistern. It was all very well to blame water companies for not supplying pure water, but when no great trouble was taking for keeping the water pure,—should it ever come into the cisterns pure,—we could not very well be angry with the water companies. The other day he was called in to examine the sanitary arrangements of a house which had recently been overhauled and reconstructed. He found about four-fifths of the work well done, but among one or two things imperfectly done was a cistern-waste. The pipe had been disconnected from the water-closet-trap and continued and made to discharge over a rain-water head. The cistern itself was on the attic-floor, and placed in a corner of the servant's bed-room. He was not then considering the position of cisterns, so he would say nothing about that, except that the water stored in such a quarter must get contaminated. The waste-pipe acted also as an overflow-pipe, and being thus open at both ends, there was nothing to prevent the foul air from the four or five lengths of rainwater-pipe over which the waste-pipe discharged, passing to the water in the cistern. The combined sink-waste and rainwater-pipe emptied itself into a large gully-trap in the back area of a house, and as such traps, as was shown in a previous lecture, were non-cleansing, every time the water was disturbed a bad smell was emitted, which partly escaped through the window just over the trap into the house, and partly found its way up the four or five lengths of foul waste-piping, and thence through the cistern-waste, to contaminate the water in the cistern and the air in the servant's bedroom. A branch waste from a sink on the third floor was taken into the combined sink-waste and rainwater-pipe, but the branch was trapped, showing that the plumber or director of the work had an idea of such piping becoming foul; but the mystery was why he carried such a pipe as a cistern-waste into it. Cistern-wastes, he repeated, should discharge themselves well away from all traps and ventilating-pipes. When they could not be made to discharge into a roof-gutter, or on to a flat or yard, and when the only place that could be found was a rainwater-head, the standing pipe in the cistern should be treated as a plug, by soldering over its top, and an overflow-pipe to the cistern should be fixed to the cistern as described for the cistern-safe, care being taken that such pipe was of sufficient size to take off the full supply of water to the cistern. If the workman erred in this matter he should err on the side of largeness.

No drain was properly connected with the sewer (or cesspool, as the case may be) which would allow the sewer or cesspool air to get into the drain, unless it was very largely mixed with the atmosphere. Every drain should be trapped off from the sewer by an efficient and self-cleansing trap, and, immediately on the house-side of such trap, an air induct pipe should be fixed to the drain; or, better still, if circumstances would admit of it, a large air-shaft should be built from the bed of the drain to the surface-level of the ground, for the upper part of the drain at such point to be well open to the air. Where the drainage of the house had been carried out on the principles laid down in these lectures, there was no risk in opening a well-ventilated drain to the air, provided the trap used for such purposes was a self-cleansing one, having a good water-seal (to allow for evaporation), and provided, also, that it was only of such a size as to admit of the whole of its standing water being changed by a flush of water sent through the drain. But to fix such an arrangement—say, for instance, in the area of a London house,—and to connect it to an old brick

drain, saturated with sewage matter, and of such a size that no amount of water that could be sent into it would flush it; or to fix it even to a pipe-drain too large to be flushed out, and, therefore, too large to be kept wholesome, was to run a great risk of getting intolerable stinks at such openings. It required good experience in such matters to treat open drains successfully; but to fix a 9in. trap where a 6in. would be ample, or to fix a 6in. where a 4in. would suffice, was to run a risk of getting bad smells into the house if the latter was near such openings, for the contents of the trap would under such circumstances only rarely be entirely changed. Where the outlet end of the drain into such traps could not be left open to the atmosphere—for various reasons, as, for instance, being an old drain which could not be properly flushed out, or because the opening would come directly under or near a window, or close to an opening into the house, or where such opening would come under a covered way where any bad air emitted from the trap or drain would get pent up, to enter the house directly a window or door near the place was opened,—then, in such cases, the opening over the top of the air-shaft or trap should be sealed up, and an air-induct pipe taken into it for the admission of fresh air into the drain from a point well removed from the house. Where the end of such induct-pipe could not be kept well away from the windows, doors, or passenger traffic, a mica valve should be fixed over its mouth to prevent, as much as possible, any drain-air escaping through it; or the induct-pipe could go up to the roof; but in the latter case the pipe should be kept lower than the up-cast pipe of the drain, so as to obtain better results from it. Though the plumber might have nothing to do with fixing such a trap for disconnecting the drain from the sewer, he had generally to do with the ventilating-pipes of the drain, for in most cases he was called upon to fix them, especially when they were of lead; and as no drain was properly ventilated unless the air in it was changed, and as that could not be done without an inlet as well as an outlet, the plumber's knowledge of drainage matters ought to extend as far as the sewer. Not that he should be required to plan the drainage of a house, but his knowledge of sanitary matters should be such as to lead him to carry out every part of his work in an intelligent manner. If sewer-air were allowed to pass freely into the drain, the whole atmosphere surrounding the upper portion of the house—where the plumber terminated the ventilating-pipes of the drain—would become contaminated, and such vitiated air would often get sucked into the house. If such smells were sufficiently pronounced to call special attention to them, they might get set down to imperfect plumbing; at any rate there would not be great wisdom in making the plumbing sanitariously perfect, and leaving the drains imperfect, for if a man was to be made ill by breathing polluted air, it might as well come from defective plumbing as from defective drainage. He supposed that at the present time the larger proportion of the house-drains of the United Kingdom were unventilated, and the other portion only imperfectly ventilated. In the scheme of house-drainage of which he exhibited a model, he had disconnected each stack of soil and waste pipe, thereby localising each of them; and that each pipe, as well as the drain, might be perfectly ventilated, he had given each its own inlet and outlet; in fact, he had treated them in the model as they ought to be treated in practice so as to secure perfect ventilation throughout the whole system. In fixing ventilating-pipes for up-casts to drains, care should be taken to keep them well above and well out of the way of all openings into the house, as explained under the head of soil-pipe ventilation in the previous lecture, so that the bad air coming out of such pipes might not get into a house through a chimney, skylight, dormer-window, or any other opening. It would really be amusing, were it not for the serious consequences likely to arise, to take note of the ill-considered positions in which such pipes were terminated. Sometimes they were seen placed where no wind could reach them at all; at other times they were left so that the slightest wind might blow the air emitted from them right into a window; and in other places, by crossing and re-crossing the roof, they were carried up some tall chimney-stack, and terminated at a point so situated that the slightest downward pressure of the atmo-

sphere pressed the bad air from such pipes down the chimneys into a sleeping or other apartments! No ventilating-pipe from a drain should be fixed inside a house if it was at all practicable to fix it outside. To prevent the possibility of drain-air escaping into a house from a ventilating-pipe through a leaky joint, broken pipe, nail-hole, or any other defect, such pipes should be fixed outside the house. When such pipes are of lead, and are wanted to stand for a century or centuries, as leaden rain-water pipes will, they should be kept out of the power of the sun as much as possible, for with soldered joints the pipe would have no freedom for expansion or contraction, as in leaden rain-water pipes with slip-socket joints.

If water-carriage was to be the system of removal, water must be used freely, if the slops and sulliage of a house were to be effectually removed; and whatever else might be limited in a house, water must not be. To make water the cleansing power of waste-pipes, soil-pipes, and drains, and then to limit its use, would be to leave the filth lodging, decomposing, and corroding in the pipes. How we should ridicule a vestry board which sent a street-scavenger to clean Regent-street, say, with one sweep of his broom, to begin at one end and push it right through the centre of the street to the other end! And yet such a swept track as that represented the treatment a soil-pipe often got. The pipe was befouled all over by an offensive excremental discharge sent into it, but the water used for washing out the pipe was only sufficient in many cases, to cleanse a channel down its sides. A pailful of slops, collected from chamber utensils, was thrown down a water-closet in a body sufficiently large to foul the whole of the soil-pipe belonging to the closet, and at the same time a water-waste preventing valve was opened for two gallons of water to pass into the closet to cleanse it; but the water, squirting into the water-closet as if it came from a boy's syringe, was of little value for cleansing the pipe, as it did not cover the whole of the parts fouled, and the parts unwashed became coated over with excremental matter, corroding up the pipe and making it unwholesome. The real cause of pipes stopping up was the want of good water flushing. It was possible to stop up a 4in. pipe to a water-closet or urinal with a bad supply of water to it quicker than a 3½in. with a good supply of water. No waste-pipe, soil-pipe, or drain could be kept wholesome unless adequate flushes of water were sent through it immediately after discharging dirty water or excremental matter into it; and before such discharges were sent through the traps they ought to be largely diluted with water—especially in such cases as the contents from chamber-utensils. Measure water into slop-sinks and water-closets by the table-spoonful, and whatever else might be clean and wholesome about the house, such fittings with their belongings would not be. He knew that it was possible to utilise two gallons of water—the quantity allowed for water-closets by the London water companies, in accordance with the Metropolis Water Act of 1871—in such a way that it should pass into a closet with greater cleansing power than twice that quantity badly supplied; but that was not the point now in question. He contended that two gallons of water were insufficient for keeping a water-closet and its belongings wholesome, and he was speaking to a body of practical men whose opinion on the matter he should be glad to hear. Were there ten men in the room who considered a two-gallon water-flush sufficient to cleanse a water-closet, basin, trap, soil-pipe, and drain after usage? ("No.") They must knock at the door of Parliament, and send in a message stating that a large body of practical plumbers found from experience that two gallons of water were insufficient to keep a "house of commons" wholesome, and that, if more water could not be allowed, such places must be abolished. Even when plenty of water could be had, however, the flush was often interfered with by bad appliances. The supply-valves, instead of being equal to flushing out a 4in. or 4½in. soil-pipe, were often only of sufficient size to cleanse a 1½in. or 1¼in. pipe; or perhaps the boiler-screw or cistern connection was of smaller diameter than the service-pipe, and the water was, so to speak, "wire-drawn" through it. The question of flushing was a very important matter, for though ventilating-pipes from drains and soil-pipes might be carried

up above the roof, the stink coming from them, where the drainage pipes were not thoroughly flushed, would be so great that the whole of the atmosphere surrounding our dwellings would at times become largely charged with the bad air emitted from such pipes, and though such bad air would no doubt get largely diluted before it was breathed, in great cities—at any rate, in a huge city like London—it would pass at times pretty freely into houses. When the drainage of London houses was properly ventilated—i.e., when every waste-pipe, soil-pipe, and drain had its ventilating-pipe, the number of such pipes would be enormous—hundreds of thousands. How important, therefore, was it that the stink coming out of such pipes should be minimised by efficient flushing.

Various opinions were now before the public as to the best method of draining a house. Several had been referred to during the lectures, and he would simply say, in concluding his remarks on "the science and art of sanitary plumbing," that it was about time that the opinions of sanitarians on such matters should be consolidated. The principles of house-drainage were so far determined upon that there ought to be no great difficulty in framing a good sanitary code as a general basis to work from. He would have the boundary lines of such a code marked out with silken cords rather than with iron bands; for, like all new things, sanitary knowledge should have room to grow. He believed it would be just as easy for a tailor to make a suit of clothes to suit all climates as it would be to lay down a code of sanitary rules to suit all cases. If he had to draw up such a code of rules, he should make them read somewhat as follows, viz.:—

1. That pure water shall be supplied to every house for dietetic purposes, and where this water cannot be drawn direct from a constant supply, it shall be stored in cisterns easily accessible for cleansing purposes; and such cisterns shall be so placed that no vitiated air can reach them, either from the house, water-closets, or ventilating-pipes,—from waste-pipes, soil-pipes, or drains.
2. That no draw-off cock to any sink or "fitting," other than a water-closet, shall be supplied from a cistern fitted in a water-closet, or standing in a place where any contaminated air can reach it, or from a cistern or service-pipe which also supplies a water-closet.
3. That every drain shall be trapped off from the sewer by a self-cleansing intercepting sewer-trap, fixed in every case outside the house; and where the mouths or inlets of such traps cannot be left open to the atmosphere, air-induct pipes should be taken into the drain immediately on the house side of such traps.
4. No drain shall enter the walls of a detached or semi-detached house.
5. In a line of houses, as in terraces and streets, where it is impossible for the drain to reach the soil-pipes without coming inside the house, such drain shall be of cast-iron, heavy water-main strength, and this pipe shall be "barfied" or coated with solution, and laid in a brick trench, or fixed on the face of the basement walls, and its joints well caulked with lead. The drain shall be so ventilated that not a foot of it shall be without a free circulation of air through it.
6. Every drain from a house shall be so ventilated that no stagnant air shall remain in any part of it; and where this cannot be done by air shafts, ventilating-pipes shall be fixed, and the drain divided into sections, and its branch drains, when of great lengths, localised, so as to insure ventilation in the entire system of drainage.
7. All soil-pipes, where practicable, shall be fixed outside the house, with their discharging ends exposed to the atmosphere,—either directly by emptying into open traps, or indirectly by foot ventilation; and such pipes shall be carried up to the highest points of the roof full size, for proper ventilation, having their terminals well removed from all openings into the roof or house.
8. All dirty-water wastes from sinks, baths, lavatories, &c., shall discharge themselves with open ends into intercepting traps fixed outside the house, and such pipes shall be continued up through the roof full size for ventilation.
9. All clean-water wastes,—from cisterns, cistern-safes, &c., shall be kept separate from other wastes, and shall discharge with open ends into the atmosphere, well away from all drain

traps or places where any bad air can reach them.

10. All wastes or overflow-pipes from safes under water-closets, baths, &c., shall be kept separate from other waste-pipes, and shall be made to discharge in the open air.

11. Every sanitary "fitting" fixed inside a house where foul matter, or contaminated water, is passed into it, or from it, shall have its waste-pipe trapped off from the house, and such trapping shall be made immediately under such "fitting."

12. All traps fixed inside the house shall be self-cleansing; and no trap which fouls itself or is not easily flushed out shall be used on the drainage outside the house.

13. All traps to water-closets, slop-sinks, sinks, baths, lavatories, &c., which can have their water siphoned out by the use of any fitting upon a pipe in connection with them, or by the use of themselves, shall be ventilated, to prevent such siphonage, and also to allow of the branch pipes being ventilated.

14. No sanitary fitting shall be fixed which will not allow a good flush of water to be sent through it to cleanse it and its belongings, to prevent any pipe from it,—be it a waste-pipe, soil-pipe, or drain,—from getting unwholesome.

15. Every house shall be provided with proper and efficient means for flushing-out the whole of its drainage.

16. The walls inside water-closet seats, the floor, and the walls of water-closets, should be made air-tight to prevent any odours in them passing to any room adjoining through a crevice, crack, or opening.

17. The rooms of water-closets should be well ventilated, so that a constant change of air may take place in them.

In conclusion, Mr. Hellyer observed that whatever charge might be laid against journey-men plumbers, want of interest in their trade could not be alleged against them, for he questioned if the members of any other branch of the great building trades would have come out night after night, during the hot time of summer, to listen to dry lectures. Lying in their strong arms, slumbering in their hardened muscles, resting in their well-trained fingers and educated hands, was, in a large measure, the health of this Leviathan city. The plumber's part in making a house, a town, a city, healthy, was enormous. He believed that if plumbing work was done on the principles laid down in his lectures, this huge city, teeming though it was with human beings, would become the healthiest, as it was now the greatest, city in the world.

ASSOS.

THE first detachment of an expedition sent out by the Archaeological Institute of America arrived in April last at Assos, and at once set about making preparations for work. The first thing done was to make a survey of the ground, noting carefully the location of the various points of interest, in order that a map might be prepared, showing the ruins just as they were found. This is now completed, and a large copy of it will soon be sent to be hung in the Museum of Fine Arts in Boston. One of the members of the expedition contributes the following account of Assos and its modern surroundings: "As one sails northward through the Strait of Adramyttium, between the island of Lesbos and the mainland, the most prominent objects in the view before him are the cloud-capped Ida on the extreme right, and the promontory of Lectum on the left. From the one to the other the mountains make a rugged, unbroken outline against the sky. Drawing nearer, a lower range appears in front of the others, directly on the sea. From the midst of these rises a cone-shaped peak, and this—the central and most commanding point along the coast—is the Acropolis of Assos. On its summit, a thousand feet above the water, stood the temple; and though there remains literally not one stone of it upon another, little effort is necessary to imagine how it must once have looked standing alone as it did against the deep blue of Egean skies. Thus beautiful in the distance, the effect is not diminished by a nearer view, for without a twist or turn one can sail directly to the base of the Acropolis, its majesty increasing every moment, until, coming into port, the objects on the upper part are lost

sight of, so steep is the ascent. It is difficult to conceive of a city more nobly placed. Even Athens is less imposing in its approach; for from the Gulf of Egea, the splendour of the Parthenon is over-shadowed by the surrounding mountains, while from every side the Acropolis of Assos attracts the eye as far as it can be seen. The hill rises, as I have said, to the height of a thousand feet; and as its inclination on the water-side is within twenty-one degrees of the perpendicular, it may well have been considered impregnable. It was on this side that the principal part of the city stood, the streets being laid out in terraces, which must have had the appearance of great steps. Here were some of the public buildings, the theatre and the porticoes, the whole crowned by the temple, from whose plane one can, as Mr. Clarke has said, throw a stone into the bottom of the ships in the little port below. The view from this plane I will not describe, because I cannot. The velvety green of the hills of Lesbos opposite, the wonderful blue of the sea which winds in all directions below, the pink and violet tints of the mountains which stretch along the Asiatic coast far into the south—all these must be seen if one would understand their charm. Looking inland, the picture seems strangely familiar. The Acropolis, which rises so abruptly from the water, sinks more gradually into the valley behind it; and one might easily imagine himself gazing from the top of some 'Prospect-hill' upon a New England landscape. To come now to the character of the city itself, or what remains of it, let us begin where we stand, upon the site of the temple. Here we have a complete ruin. A few stones still appear above the ground to give some idea of the outline of its foundation, and undoubtedly a little digging will bring more to light; but not one column remains in its place. Drums and capitals lie about in disorder, many having rolled down the hill to lodge where they might. Scattered as they are, however, some of the fragments are in fine condition, showing that the temple was of a dark grey stone, and built at an early period of Doric art. Fortunately, enough pieces have been discovered already to determine the size and proportions of the building, so that a drawing of its original appearance may be possible. A little more than a hundred yards below the temple are the remains of two long stoæ, or public porticoes, one below the other, built into the side of the hill. These were probably the principal places of resort, where, protected from the heat of the sun, the people could meet for business or conversation. The remains are much more satisfactory than those of the temple, being, in fact, among the most interesting of all the ruins. Their walls, imbedded in the hillside, are almost intact, each showing a row of large square holes, into which the beams that supported the roof were fitted. The pavement, though now covered with rubbish, is thought to be in fair condition, and the parts of several columns remain in place, to show the height and character of the structures. Midway between the stoæ and the portico lies all that is left of the theatre. Not many years ago this theatre was so well preserved that Texier pronounced it the finest of all the many theatres of Asia Minor, and in some respects of all Greek lands; but recently it has been used so extensively by the Turks as a quarry for buildings at Constantinople that now nothing but the barest outline is left, with here and there a slab in place to give a faint idea of its former character. Like the Dionysiac Theatre at Athens, it was dug out of the slope of the Acropolis, facing directly on the sea, and from it the spectators saw not only the opposite shores of Lesbos, but far down the Strait of Adramyttium in the direction of Smyrna. The site of the stage is now covered by a few rudely-made cow-pens, the removal of which may be of assistance in determining at least its outline. Passing now to the sides of the Acropolis, we come to the most magnificent feature of the remains—the walls. These give to Assos a character which no other Greek city has retained, for they are in such fine condition that their entire outline can be easily traced; and though, like the theatre, they have been used extensively as quarries, they are still thirty feet high in many places. From either side of the Acropolis they run in zigzag lines to the right and left, showing in different places three distinct styles of building, of as many periods—the rude, so-called Cyclopean; the polygonal, and the Macedonian, the latter of which is the

best preserved, and of admirable workmanship, the large stones being laid in courses as even and regular as those of the brick walls of any of our houses, apparently without the aid of mortar. Several of the gateways remain in their original condition, flanked by massive towers; and show the curious striving for the principle of the arch, the stones being laid in converging horizontal courses, in the manner made familiar to us by the discoveries at Mycenæ, though the examples at Assos are of a much later date. In the walls we have evidence, not only of the early and long-continued civilisation of the city, but also of its importance; for, as the space inclosed has been estimated roughly at about fifteen square miles, the population must have been large. Another proof of this is given in the extent of the cemetery which lies outside. Beginning at a gate west of the Acropolis, the street of tombs extended quite a distance directly inland, turning then to the right, and crossing to the eastern end of the city. It seems to me impossible that this sacred way can receive the attention it deserves in a single season, so considerable is the ground it covers, and so profusely are its remnants scattered. As one tries to trace its course, the fragments of huge sarcophagi lie about him on every side. Here he finds the broken half of a stone vault, there his foot stumbles upon a displaced cover; further on stands a sarcophagus large enough to have held two men, which would have been complete but for a hole in the side, through which it was robbed long ago. These sarcophagi, some of which are colossal in their proportions, form but one of many kinds of tombs in which the place abounds. It is certain that here some of the most interesting labours of the expedition will be carried on; and perhaps—who can tell?—the popular eagerness for a "find" may here be gratified; for although the sarcophagi themselves offer no grounds for hope, there are many large tumuli and tombs—to say nothing of the graves below the sarcophagi—from which it is possible that at least some well preserved specimens of Greek pottery may be brought to light. However, it must be borne in mind that the Institute sent out this expedition not so much for the purpose of discoveries as for careful investigation; and, although it would be gratifying to unearth some work of art, the main object will be accomplished if we can carry home with us nothing more than a thorough knowledge of the city. A result like this is not a matter of chance, and, if intelligently attained, America will have the honour of contributing to the world's knowledge of the civilisation of ancient Greece—an achievement in which every American scholar may take a just pride.

UPPER ROOMS AS OVENS.

IN the construction of perhaps nine out of ten frame houses, and oftentimes of brick, no adequate provision, if any, writes Dr. Newkirk, a correspondent of an American contemporary, is made for ventilating the space between the upper ceiling and the roof. How frequently at night the remark is made: "The lower rooms are getting quite comfortable, but the upper rooms are like an oven." "The roof gets so heated up during the day." Seldom is the real cause of the oppressive heat that prevails till late in the night, or till well on towards morning, either understood or thought of. It is true the roofs get hot during the day, but it usually consists of but a layer of strips and shingles and would soon cool if it had a chance. The trouble is there is a body of confined air under the roof that gets very hot, and as there is no outlet for its escape and replacement, it must remain hot until cooled by the slow process of radiation through the surrounding walls.

Now, the roof being usually of wood is not so good a conductor as the plastered walls of the ceiling, hence the heat must pass out principally from below through the rooms of the house. That accounts for the fact that when one goes to an upper room in the evening there comes such a sense of stifling, and the sweat starts from the forehead. It is an oven you are in; all that is lacking to make it complete is the hot-air chamber below as well as above. The builder who constructs a house with such nicely adjusted conditions for the radiation of stored-up heat, might most properly be called Macbeth, for he has certainly "murdered sleep." When the writer was a boy it was his good fortune to

sleep in the chamber of a house unfinished above. There was nothing but the roof over him, and the room became cool not long after the cooling of the outside air. It was a good place to sleep winter or summer.

Only those who have slept just under the shingles can realise what it is to "listen to the patter of the rain upon the roof." Very often in steeped roofed and low-eaved houses a part of the room along by the eaves above is walled out, leaving a space for confined air on two sides as well as above. The sides, too, are connected with the spaces between weather boarding and walls, reaching to the sills. It will readily appear, therefore, what an advantage would be gained both in preventing and reducing excessive heat by having a free circulation of air through these spaces. The provisions sometimes made for this ventilation are insufficient. A few open slits under the roof in the gable are better than nothing, but there is no good reason why there should not be at least two good large openings. An arrangement could easily be made so that shutters should be under control from below, by means of a cord or wire, remaining open day and night during hot weather except when storms might threaten. They might be made to assist greatly in cooling and ventilating the whole house.

NATIONAL ASSOCIATION OF MASTER BUILDERS OF GREAT BRITAIN.

THE half-yearly meeting of this association, held at 27, King-street, Covent-garden, on Tuesday week, was attended by representatives of upwards of 140 local associations. The occasion being so important was embraced by the London builders as a fitting opportunity to entertain their provincial brethren. A numerous gathering dined at the Criterion in the evening. Mr. Stanley G. Bird (the president) occupied the chair, and amongst those present were: Mr. R. Neil, jun., Mr. B. Hannen, Mr. Ex-Sheriff Burt, Mr. T. Clay, Mr. G. Plucknett, Mr. W. H. Cowlin, Mr. E. Hughes, Mr. J. Whiteher, Major Waller, Mr. J. Leslie, Mr. C. W. Barker, Mr. J. B. Simpson, Mr. L. J. Maton, Mr. A. Bird, Mr. J. T. McLachlan, Mr. W. C. E. Creswick, Mr. W. Knox, Mr. W. Clulee, Mr. Bennett, Mr. Beandlan, Mr. Malone, Mr. J. H. Colls, Mr. J. T. Chappell, Mr. W. A. Colls, Mr. H. G. Smith, Mr. A. J. Mansfield, Mr. A. R. Smith, Mr. R. Gurney Hoare, Mr. J. McLachlan, Mr. J. Bradney, Mr. T. E. Phillips, Mr. W. Bird, Mr. C. Bird, Mr. Bonnar, Mr. C. J. Bennett, Mr. A. Thorn, Mr. T. Patrick, Mr. H. Kelly, Mr. E. Kelly, Mr. S. E. Haward, Mr. J. Clemence, Mr. J. Wall, Mr. Barfield, Mr. T. Hook, Major Brutton, Mr. G. S. Pritchard, Mr. R. D. Lown, Mr. H. Dove, Mr. Callaghan, Mr. Nightingale, Mr. J. C. Hannen, Mr. W. Southern, Mr. Kirk, Mr. Randall, Mr. Doulton, Mr. Marsden, Mr. Edwards, Mr. Chambers, Mr. H. Burman, Mr. Little, Mr. Dove, Mr. Collingridge, Mr. Stedman, Mr. Duffield, Mr. Webster, Mr. Adamson, Mr. F. J. Dove, and Mr. E. S. Henshaw.

The loyal toasts were given from the chair, and duly honoured. Mr. E. Hughes proposed "The Army, Navy, and Reserve Forces," Major Brutton (secretary of the Builders' Benevolent Society) and Major Waller responding. Mr. Plucknett gave the toast of the evening, "Success to the National Association of Master Builders of Great Britain, and the Health of the President," which was received with cheers. He said that, considering the short period of the Society's existence, the results that had been attained were extremely gratifying. Many of the leading builders of the country had already joined them, and he felt sure that motives of self-interest, if no other motives, would induce all the great building firms to enrol themselves in the list of members. He himself looked forward to the time when, through the operations of this society, strikes and lock-outs would be things of the past. With the toast he desired to couple the name of their president, Mr. Stanley G. Bird, who had worked zealously for the objects of the association, and without whose courage and perseverance at the commencement he doubted whether it would ever have come into existence. Mr. Bird, who was heartily cheered, said he felt himself justified in declaring that the Association of Master Builders had already rendered to the trade services of a most important character.

He doubted, however, whether it was possible yet to foretell the happy period when strikes should be at an end; on the contrary, he believed that with a return of prosperous times their troubles would commence again. At that time, however, the trade generally would understand the immense advantage of being able to refer their difficulties to such an institution as this. Alluding to specific objects that had already been attained through the instrumentality of the Association, he mentioned a new form of contract, and the establishment (out of the Employers' Liability Act) of the Builders' Accident Insurance Company. Mr. Hannen gave "The Local Associations of Master Builders," insisting upon the advantages rendered by these institutions. Mr. R. Neil and Mr. W. H. Cowlin replied. Mr. Clay responded for "The Visitors."

THE NEW EDINBURGH DOCK AT LEITH.

THE new dock at Leith, which was opened last week by the Duke of Edinburgh, lies east of the Albert Dock, which is the most recent of the existing basins, having been completed in 1869. Access to it is obtained through the Albert Dock, and the connecting passage is spanned by a massive swing-bridge, which is adapted both for railway and for ordinary traffic. The Albert and Edinburgh Docks are protected by a solid reclamation bank upwards of a mile in length. This embankment is in itself a stupendous piece of masonry. The wall is 20 feet broad at the base and 10 at the top, and in its construction 100,000 tons of rubble and 8,000 cubic yards of ashlar and concrete were used. The breadth of ground reclaimed between the face of the embankment and the old foreshore varies from 1250 feet to 1400 feet—that is to say, it averages a quarter of a mile. The breadth of ground between the new dock and the sea is 225 feet, which affords ample space for sheds, lines of railway, and roadways. The new dock is 1500 feet long and 650 feet wide; but there projects into it from the middle of the eastern end a jetty 1000 feet long and 250 feet broad. At that end, therefore, the breadth of water on each side of the jetty is only 200 feet. But what is thus lost in water area is more than compensated for by the increased accommodation for berthing vessels and for wharfe and sheds. At the west end of the jetty there is a graving dock 300 feet long. This is smaller than the Prince of Wales's Graving Dock in connection with the Albert Dock, which is 470 feet long; but it will be a valuable addition to the conveniences of the port. The superficial area of the new dock is 16.2-3 acres. The Albert Dock, which is the largest of the existing docks, extends only to 10½ acres. The wharfe of the Edinburgh Dock is, in linear measurement, 4,000 feet, or upwards of three-quarters of a mile. The foundations rest on blue boulder clay. The whole works, including the railway undertakings, were estimated to cost £400,000. They have been carried on during the last five years by the trustees of the late Mr. Scott, under the personal superintendence of Mr. Scott, jun., Mr. Best, and their engineer, Mr. Clark, C.E. Including the Edinburgh Dock, there will now be five wet docks in connection with the port of Leith—three on the west side and two on the east of the inner harbour. All these docks have been constructed within the present century.

IRON PIPES.

IN the selection of iron pipes some practical knowledge is necessary to discover weak castings and imperfections of detail. One of the principal points to be observed is equality of thickness all round. In pipe-casting the core is sometimes not true, or the section of the pipe shows the core to be not concentric with the outside. In such a case a pipe is necessarily weaker, because thinner on one side than the other, and even if strong enough to stand the test, its margin of strength is not what it ought to be. Now, pipes cast with eccentric cores can only be judged of by careful inspection of the ends. With regard to the usual "spigot and faucet" joint, it is now considered, where a solid foundation is met with, almost as cheap, as it is certainly economical, to turn the spigot to fit a bored socket, both being slightly tapered, by which means as the ends are brought to-

gether they fit to a nicety; a mere smearing of white lead, or other caulking, is then sufficient, and all the labour of filling in the loose end of spigot to make it fit the socket is saved. The pipes are quicker laid, and the bore can be ranged with more accuracy. The chief advantage of the old socket plan is that it allows of play, and in case the pipes are laid in a bid or yielding soil, the large socket with its caulking allows for settlement, and is not so liable to break off as a turned socket is. For flange-jointed pipes, the advantage of turning is great, as straightness and accuracy are more essential. The loss of water by leakage in most towns has been found to be very considerable, and the percentage of leakage to the total consumption is largely due to imperfect jointing. With regard to the quality and weight of iron, that re-melted from pig-iron is considered the best. One authority gives a weight of 25wt. as a minimum test load. In specifications it is usual to specify a vertical position for casting; careful ganging of the pipe is necessary to see that the bore is perfect, and that the pipes are concentric. Testing by water-pressure is, of course, very necessary, and a pressure equal to a column 300ft. high, or equal to 130lb. to the square inch, is adopted by many as sufficient. Specifications ought to state thickness, weight, tenacity, as well as a water-pressure test of the usual kind, as the water-test has sometimes been found misleading.

INTERNATIONAL COMPETITION FOR A MEMORIAL CHURCH AT ST. PETERSBURG.

A COMMUNICATION has been received from the Foreign Office, in a letter from Lord Tenterden addressed to the President and Council of the Royal Institute of British Architects, to the effect that British architects are invited to join in a competition for a church to be erected at St. Petersburg, on the spot where his late Majesty the Czar was assassinated. The designs must be submitted to the Town Council before the 12th of January, 1882; and the conditions, &c., of the competition, extracted from the *Journal de St. Petersburg*, are contained in the following paragraphs:—

(Translation.)

Extract from the *Journal de St. Petersburg*, May 25. (June 9), 1881.

"In pursuance of a resolution passed by the Municipal Council of St. Petersburg to erect a stone church, dedicated to the Russian Orthodox Ritual, and to be sacred to the memory of His Majesty the late Emperor Alexander II., a competition is opened for the design of this edifice, under the following conditions, viz.:—

"1. The design must be so arranged that the church has three altars, the spot where His Majesty the late Emperor fell mortally wounded (shown on the plan by a cross) may stand in the centre or at the right angle of the western part of the church. This spot may be considered as treated as constituting the object of an annexed part of the edifice, though it must nevertheless form one and the same connected design of the church as a whole.

"2. The foundation-line of the west elevation of the church must not advance into the bed of the canal to an extent exceeding 7ft. as indicated by the line *a* on the plan, but the steps of the *parvis* of the church may be placed upon the bridge.

"3. The basement is not intended to be applied to any purpose other than to provide room for the heating and ventilating apparatus and the storage of fuel.

"4. The church must be designed to hold a congregation of 1,000 persons, upon the principle of allowing 7ft. square to every 16 persons. (The number of 16 persons per square *sagène* (7ft. by 7ft.) is fixed, because the Russian Orthodox Ritual does not admit of the worshippers being accommodated with seats during Divine Service.)

"5. The position of the tower or that part of the building which is to contain the bells is left to the choice of the competitors.

"6. Competitors are also required to submit designs for the ornamentation of the bridge, which is to cover part of the canal so as to form a square in front of the church; and of the ornamentation of the part of the Palace Michel which will surround it.

"7. The designs must include:—(a.) Detailed plan of the church, two elevations, one a lateral one and the other facing the park, and also a section; these drawings to be prepared to a scale of one inch (English) to the *sagène* (7ft.). (b.) The west elevation and another section must be drawn to a scale of two inches (English) to the *sagène*. (c.) A general plan, on the scale of one inch to five *sagènes*. (d.) A perspective view of the church with its approaches. (e.) An explanatory memorandum stating among other details the cubic capacity of the church, computed in *sagènes*, and describing the nature of the materials to be used in the construction.

"Competitors may elaborate the details of the building as they may deem fit.

"8. Russian and foreign artists are both eligible to take part in this competition.

"9. The designs must be submitted at the office of the Municipal Council of St. Petersburg at the latest on the 1st of December, 1881 (12th of January, 1882), at noon.

"The general plan of the site whereon the church is to be erected may be had on application either to the *Gérant*

of the Town-hall of St. Petersburg, or to the offices of the newspapers in which the present notice appears.

"10. For four designs sent in by the appointed time, which fulfil the conditions laid down in the present programme, and are allowed by the jury to be the best in order of merit, the Municipal Council will grant four premiums. For the first in order of merit, 2,500 roubles; for the second, 2,000 roubles; for the third, 1,500 roubles; for the fourth, 1,000 roubles.

"11. All designs must be sent in a portfolio, and not rolled up in a case.

"Every sheet of the drawings, as well as the explanatory memorandum, must bear a motto chosen by the author of the design. The names, rank, and address of each competitor must be supplied in a sealed letter, bearing the author's motto on the cover.

"12. All the designs sent in will be exhibited to the public during eight days in the Town-hall. After the decision of the jury the successful designs alone will be exhibited again in public.

"13. The jury undertake to publish a short memorandum setting forth succinctly the merits and defects of all the designs presented. The names of the premiated competitors will be published in the journals in which the present notice appears.

"14. The prize designs will become the property of the Municipal Council of St. Petersburg. The designs not selected for the prizes will be returned, together with the respective letters unopened, upon presentation of the receipts originally given by the *Gérant* of the Town-hall.

"15. Members of the jury are debarred from participation, direct or indirect, in the present competition.

"16. The premiums awarded will not entitle the successful competitors to take part in the construction of the church. The committee appointed by the Town Council reserve to themselves the selection of the architect to be intrusted with the execution of the works.

"17. The jury consist of the following members of the Council of the Imperial Academy of Fine Arts, viz.:—Professors A. Rzhanov, D. Grimm, A. Krakau, and W. Schreiber; of the following members of the St. Petersburg Society of Architects, viz.:—Professors R. Bernhardt and E. Gibert; and of the Mayor of the City, as well as of four delegates appointed by the Municipal Council."

The Municipal Council have sent to the Institution a few copies of the "plan of the site set apart for the erection of the proposed church," and these are at the disposal of gentlemen desirous of joining in the competition.

A ROMAN AQUEDUCT 1,600 YEARS OLD RESTORED.

AFTER a lapse of 1,600 years the aqueduct built by the Emperor Augustus to supply Bologna with water was restored to use June 5th. Nineteen hundred years ago the imperial engineers tapped the Setta near its junction with the Reno, about eleven miles from Bologna, and brought its water to the city through an underground passage. They followed the course of the Reno, tunnelling the hills, sinking their work beneath the beds of the precipitous torrents which rush from the mountains into the river, and bringing the waters to the gates of the city, where they are divided, one portion going to supply the public-baths, and the other probably destined for the fountains of streets and public squares.

The work of tunnelling and the masonry were so thoroughly well done that both stonework and brickwork are still as solid as the rock itself, the only considerable breaks being where the turbulent Reno had washed away with its clayey banks several portions of the aqueduct, or where the headlong torrents which rush down into its stream had excavated their own beds and carried away the artificial substructure.

The restoration of this important work is due chiefly to Count Gazzadini, who caused an accurate survey of the aqueduct to be made about twenty years ago, and in 1861 published the results of the investigation in an elaborate memoir. Since then the work of restoration has been going on with a thoroughness and skill calculated to make the new work as enduring as the old. The aqueduct was originally made of brick and stone cemented with lime and volcanic sand, and the unbroken portions remained as hard as granite.

Various correspondents of the *Times* are suggesting the removal of the organ-screen at Westminster Abbey, and the transference of the clergy and choir to the space east of the transepts. The screen is, no doubt, thought by some a great eyesore; but the proposed arrangements could hardly be carried out unless the altar-screen and St. Edward's shrine were also removed and the altar placed in the apse. Precentor Venables has written strongly against the scheme.

The chapel of Lincoln's Inn, which is said to have been designed by Inigo Jones, is, according to the *Solicitors' Journal*, about to be altered and enlarged, under the superintendence of Sir Edmund Beckett, Bart., Q.C.

"BENT'S BROOK," HOLMWOOD, SURREY.—DESIGN FOR A TOWER AND STEEPLE.—ST. MARY'S CHURCH, HAMMERSMITH.—SKETCHES OF OLD DOMESTIC WORK.

OUR LITHOGRAPHIC ILLUSTRATIONS.

ARTISTS' HOMES: NO. 14, "BENT'S BROOK."

ONE of our double-page plates to-day illustrates the residence of Mr. J. E. Boehm, A.R.A., the sculptor. Bent's Brook is situated at Holmwood, not far south of Dorking, on the Mid-Sussex line, and commands some fine views of well-timbered country. The site itself is comparatively low, and the soil being clay, it was advisable to keep the building well out of the ground, and in this way a rather unusually high elevation for such a house was obtained. The plan is very compactly arranged, with an ingenious approach to the well-centred hall and staircase, over which, by a mezzanine contrivance, a good store-place is secured. The drawing-room has a belvedere bay, reached from the garden by an external stair, under which is a covered-garden seat. A balcony overlooking the garden leads also from the drawing-room, and a billiard-room is arranged on the basement-level with a separate entrance from the porch. A tradesman's entrance is provided elsewhere. The kitchen and offices are on the lower-floor level, and a kitchen-yard is conveniently placed at the rear. Red brick, with cent-brick dressings, is the material used throughout for the walls, the upper parts of which are hung with ornamental tiles. The gables are enriched with wide, massive barge-boards, and the roof is surmounted with a white wooden cupola over the principal staircase. The terra-cotta panels along the entrance front, over the principal-floor windows, were designed by Mr. Boehm himself. The work was executed by Mr. H. Batchelor, builder, of Betchworth, and the architect of the house was Mr. R. W. Ellis, F.S.A., who superintended its erection.

THE GRISSELL GOLD-MEDAL DESIGN FOR A TOWER AND STEEPLE.

THE competition for the Grissell medal this year was unusually well-contested, five sets of drawings having been sent in of so much merit that the Council in the awards to four of them. The gold-medal drawings which we publish to-day fully illustrate the chief difficulties, artistic and constructive, to be overcome in dealing with a subject of this kind—namely, the mode of joining the steeple to the tower. Many of our English spires, which are beautifully proportioned when seen from the front, appear faulty when viewed on the angle, for while the spire continues the same width the tower appears wider in proportion as the diagonal of a square is greater than its side, thus making the spire seem too small for the tower, or as if it had been "telescoped" into it, and wanted pulling up. This defect is avoided in the gold-medal design

by tilting the base of the spire, which, though certainly not an original idea, is not so often resorted to as it might be with advantage when the tower is finished with a gallery and parapets. The transition from the vertical lines of the tower into the raking lines of the spire is further softened in this design by placing the large pinnacles in the centre of the wall instead of at the extreme angles, which are sufficiently marked by smaller ones. An unusual degree of picturesque richness has been given to the belfry stage by using three planes of tracery, showing the full thickness of the wall, thus combining an appearance of strength with lightness, besides casting deep and effective shadows. The construction employed is fully illustrated by the interior perspective sketch and detail sections.

PROPOSED CHURCH OF ST. MARY, HAMMERSMITH.

THE proposed Church of St. Mary, Hammersmith, is specially designed to enable the congregation to see the pulpit, and the east end of the church, with a wide nave of 35ft., narrowing to 30ft. at its east end, and with a chancel 24ft. wide. The decrease in the width of the nave is almost entirely hidden by the intersection of the nave and transept roof. The turret will serve both for a bell and ventilating-turret. The materials used will be stock bricks with red-brick dressings, and red tiles for the roof; £8,200 is the cost estimated by the architect, Mr. Arthur Baker, 14, Warwick-gardens, Kensington.

SKETCHES OF OLD DOMESTIC WORK.

WE regret we have no description to hand of these sketches of old domestic work in Essex and Suffolk. They are very interesting, and many readers would have been glad to have known more about them.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

NEWCASTLE SOCIETY OF ANTIQUARIES.—Last week the Newcastle Society of Antiquaries held a meeting in the Old Castle. The Rev. Dr. Hooppell, who was unable to be present, drew the attention of the society, in a letter, to the foundation of what appeared to him to be a very ancient building at Pandon-hill, at the extremity of the wall in Causey-bank, and between the Sallyport-gate and the river. The building adjoined the wall, and was 30ft. wide, over 60ft. long, and the walls were 6ft. thick. He suggested that the contractor should be seen, and, if possible, a man should be employed by the society to explore the foundations. The Rev. Canon Greenwell was of opinion that they should have a plan made of the building spoken of in Dr. Hooppell's letter when it was properly excavated, and suggested the appointment of some person to do this. Alderman Cail said he would see the contractor, and ask him to give them notice if he came upon any other wall (because it was likely that the Roman Wall was to the south of the present one), or any other object of interest, and perhaps Mr. Holmes would take a sketch of any such objects. Mr. Holmes promised to do so. The matter then dropped, and the secretary drew attention to the question of restoring the Black-gate. Alderman Cail said a committee appointed to consider the question had made some plans, which he supposed would be in their possession. They thought that two good floors might be put in, and the present hideous top removed, and a more fitting one substituted for it. The building might then be made a museum for all the smaller objects they had in the castle, which could not now conveniently be seen. With that view, he should propose that they approach the corporation, and ask them on what terms they would let it to that society. Mr. R. S. Johnson explained the plan of the suggested alterations, which he said would cost about £1,300. Some further discussion took place, in which it was suggested that the corporation should be asked to restore the building, and in the event of their doing so that the society should hand over their museum to be placed in it, on the condition that they were appointed the custodians of the place. Ultimately it was agreed that the corporation should be asked to appoint a committee, with which the committee of the society having the matter in hand might have an interview on the subject.

SOMERSETSHIRE ARCHÆOLOGICAL AND NATURAL HISTORY SOCIETY.—The thirty-third annual meeting of this society is to be held at Clevedon on Tuesday, 23rd August, and two following days. On Tuesday, 23rd August, the annual general meeting will be held at the Public Hall, when an opening address will be delivered by the president, and papers read. In the afternoon the following places will be visited—Clevedon Court, Yattton Church, Old Rectory House, and Clevedon Old Church. In the evening there will be a meeting at the Public Hall for papers on subjects of local interest, and for discussion. On Wednesday, the 24th, there will be excursions to Twickenham Court, Twickenham Church, Tower House, Wrasall Church, Ashton Court, Long Ashton Church, Flax Bourton Church, Backwell Church, Chelvey Church, Chelvey Court, Nailsea Court, and Nailsea Church. There will be an evening meeting at the Public Hall for papers, &c. On Thursday, the 25th, the society will leave the Public Hall, Clevedon, for Cadbury Camp, Clapton-in-Gordano Court, Clapton-in-Gordano Church, Portbury Priory, Portbury Church, Portbury Camp, Portishead Church, Portishead Manor House, Portishead Quarries, and Weston-in-Gordano Church. Mr. E. B. Ferrey will describe the various points of architectural interest visited during the excursion; the Rev. H. M. Searth the earthworks at Cadbury and Portbury; and the Rev. H. H. Wiuwood will explain the geology of the Portishead quarries.

WARWICKSHIRE FIELD CLUB.—An archaeological excursion of the Warwickshire Naturalists' and Archaeological Field Club took place on Wednesday week, when Ashby-de-la-Zouch was the chief place of interest. The party first inspected the ruins of the castle, erected by William Lord Hastings, in the reign of Edward IV., and one of the places of detention of Mary Queen of Scots. Passing to the church the Rev. J. Denton explained the recent restoration and enlargement. The church dates, probably, from the 14th century, and was much altered in the 16th. The Hastings Chapel forms the south side of the chancel; the north side of the chancel is the vestry, over which is a spacious chantry, which was put to good use in the latter part of the 16th, 17th, and early 18th centuries, being converted into a library. In the vicarage garden are remains, some very good, of window mullions from the church, removed, but reproduced. There is also a sundial, once in the possession of Sir Isaac Newton. One chalice, silver gilt, is Elizabethan—the base of it is Medieval; another chalice is supposed to be the cup given by Edward IV. to the Earl of Huntingdon. Staunton Harold Church was next visited, and is interesting, because the only church restored under Cromwell (1653); it contains some fine monuments of the Shirley family. The hall is the seat of Earl Ferrers. After inspecting this mansion the party proceeded to Calke Church and Abbey, and the Norman Church of Melbourne, restored by Sir Gilbert Scott. Time did not permit the completion of the programme, which included Breeden Church, formerly a conventual one, and beautifully situated on the summit of the Bulwark-hill, with the adjoining traces of a priory, the remains of the abbey at Grace Dieu, and the slight ruin of the castle built in the reign of King John.

CHIPS.

The Queen has conferred the honour of Knighthood on Mr. F. J. Bramwell, civil engineer, in consideration of his services to technical education, and on Mr. James Allanson Picton, F.S.A., F.R.I.B.A., of Liverpool.

The restoration and enlargement of the parish church of Northchurch has been finally determined upon, and operations have been commenced. Mr. Cook, of Berkhamstead, is the contractor.

Messrs. Thomson and Co., of Birmingham and Manchester, have just supplied a dwarf screen, gas-fittings, and altar-furniture to St. James's Church, Wednesbury. The same firm are making a very elaborate screen for the church of St. Michael, Handsworth, Birmingham.

The new church of St. Paul, in Santley-street, Brixton, S.W., was consecrated on Friday by the Bishop of Rochester. It is built of brick, with Bath-stone and terra-cotta dressings; and seats, including accommodation in side galleries, 1,610 persons. The architects are Messrs. Habershon and Fawcner, of 38, Bloomsbury-square, and the builders, Messrs. D. C. Jones and Co., of Gloucester. The cost has been nearly £11,000.

SKETCHES OF OLD DOMESTIC WORK BY F.W. WOODHOUSE

ROYAL ARCHEOLOGICAL INSTITUTE.

WEDNESDAY week, the second day of the Archeological Congress at Bedford, was devoted by the archaeologists to a rather long journey by rail and carriages to Leighton Buzzard, Wing, Stewkeley, and Edlesborough, the churches of which places were severally explored under the guidance of Mr. J. H. Parker, Mr. M. H. Bloxham, and others. At Leighton, the fine tower and spire, the scroll-work on the south door, and the restored market-cross came in for their share of admiration. At Wing, the ancient crypt, believed to be very Early Saxon, if not Roman work, was inspected, Mr. J. H. Parker acting as interpreter. The great likeness between Stewkeley and Ilfley churches was made the subject of remark by the visitors, who were obliged to content themselves with a hasty visit, as luncheon was waiting them at Edlesborough. Here they inspected the Early English church recently restored, and also an ancient barn, with windows and timbers of at least Early Tudor date. After luncheon they drove to Eaton Bray church, another very fine specimen of the Early English style; thence to Dunstable, where the excellent reparations in progress in the old Priory Church received due acknowledgment. The Bedfordshire Architectural Society has lately voted a grant of £50 in aid of these works, especially on the north aisle, but a far larger sum is needed to complete the fabric. The company were also shown over the prior's house, and part of the old Royal Palace. From Dunstable they returned by railway, *via* Luton, to Bedford, which they reached after a long but pleasant day. In spite of a shower or two, the weather was delightful on the whole, and the day was pronounced a great success. In the evening the President and Council of the Institute gave a *conversation* at the Bedford Assembly Rooms, which was numerous and fashionably attended. The company were much interested by a collection of Bedfordshire antiquities and art-treasures; specimens of Roman and British pottery; copes and altar cloths from neighbouring churches; engraved portraits of innumerable members of the house of Russell (from Woburn Abbey) and of the Byng and Whitbread families; an original portrait of the Lord Protector, and one of his military boots; and several portraits, autographs, and other "relics" of John Bunyan, including his drinking cup, his little oak cabinet, and his chair, which was lent specially by the trustees of the chapel where it is kept. But, perhaps, the chief interest was felt in the ring given by Queen Elizabeth to Lord Essex, the non-production of which, at a critical moment, cost the Earl his life. This was lent by Mr. F. J. Thynne, of Hawnes, near Amptill, one of the vice-presidents of the meeting. The papers read on Tuesday evening were as follows: On "Chancer's Monument in Westminster Abbey," by Mr. M. H. Bloxham; on "The Church of St. Mary, Bedford," by Mr. G. Hurst; and on "St. Paul's Church," by Mr. J. Day.

Thursday morning was devoted to the annual general meeting of the institute, which was held in the Bedford Assembly Rooms, under the presidency of Lord Talbot de Malahide. The annual report, which was read and adopted, recorded the fact that the Council had joined with the Society of Antiquaries in considering the steps necessary for the preservation of Stonehenge, and had also entered its strong protest against the destruction of the west front of St. Alban's Abbey, which is still going on under the name of "restoration." Lord Talbot also announced that the institute had received from the Bishop, the Chapter, and the municipal authorities of Carlisle a pressing invitation to hold the Congress at Carlisle next year, and that the invitation had been accepted. At the close of the meeting, the carriages and brakes were ordered, and the party, about fifty strong, left for Cople Church, where they inspected the monuments, brasses, and heraldic bearings of the Launceylons, Lukes, Rolands, and Greys. The next halting-place was Willington, where the monuments, and especially the helmet and tabard of Sir John Gostwick, Master of the Horse to Henry VIII., were inspected. These, it was stated, were probably worn by him on the Field of the Cloth of Gold. Leaving Willington, Sandy was reached at a little after one, when the party sat down to lunch at the Greyhound. At two they proceeded to Caesar's Camp, in the

pine woods, above the town. Thence they made their way to Galley-hill Camp, where a similar construction was noticed. The general opinion was that these camps were of British, not of Roman origin, though they might possibly have been used by the Romans during their occupation of this country. In the course of the afternoon they were entertained at afternoon tea by Mr. J. N. Foster, one of the vice-presidents of the meeting, at Sandy Place. They afterwards inspected Howbury Camp and Risinghoe Castle, two curious earthworks, probably also of British origin, and erected to defend the fords across the river. The return journey to Bedford was then made. In the evening there were sectional meetings in the Bedford-rooms, when several papers were read by Messrs. Wormall, Copner, Micklethwaite, and others. In the Archeological and Historical Section, the Dean of Ely gave the members an interesting address on the history of Bedfordshire, in the course of which he alluded to the fact that, except during the struggles of the Civil War, that inland and level county had never played a conspicuous part in the annals of England, and paid it a handsome compliment as the nurse of John Bunyan.

On Friday the expedition organised was to St. Alban's and to Luton, by railway. At St. Alban's the archaeologists were met by a large contingent from London, and by several members of the association, who were conducted over the building by Mr. J. T. Micklethwaite, F.S.A. He explained the various features of the structure, from the first foundation of the present Abbey in the early Norman times, when Saxon and Roman materials were worked into the walls of the new fabric. He afterwards commented on the portions of the great work executed by Abbots de Cella and Trumpington, and by Abbot Wheathampstead, who, he said, was the designer of the fine west window now in course of demolition by Sir Edmund Beckett. He also explained the curious history of the recent discovery and reconstruction of the shrines of St. Alban and St. Amphibalus (though he seemed to regard the latter saint as somewhat apocryphal), and illustrated the singular history of the preservation of the central tower and of the Lady Chapel. The archaeologists wished for admission to the western portion of the nave, but were refused, so they went outside the west front to survey and deplore the work of destruction, Mr. J. H. Parker stating publicly that he regarded the newly-designed window as a "grave mistake." The company, having lunched at the Peahen, inspected the church of St. Michael and the monument of Lord Bacon, and then reconnoitred the remains of Old Verulam and of the British city on the banks of the Ver, the abbot's boat-house, and the large earthworks at Bernard's-heath. In the course of their return journey they visited the large and handsomely-restored parish-church of Luton, with its exquisite and antique baptistry, and the Wenlock Chapel. Having reached Bedford in good time, they met again in the evening, at the Assembly Rooms, where papers on "The Earthworks of Bedfordshire," on "The Mural Paintings at St. Alban's," and on "The Churches and the Bells of Bedfordshire," were read by Dr. Prior, Messrs. Ridgway-Lloyd, Foster, and North.

On Saturday the archaeologists had a long day, the pleasure of which was slightly interfered with by the rain which fell in the morning and afternoon. In spite of the weather, however, they contrived to visit Clapham Church, conspicuous all round by its lofty Anglo-Saxon tower. From thence they drove on to Colworth-house, where they were hospitably received at luncheon by Mr. Charles Magniac, M.P., and the Hon. Mrs. Magniac, who exhibited to them the art-treasures for which the house is famous—books, prints, pictures, and old china, including a vase of Henry II. ware, a "Maximilian" suit of armour, a fine full-length portrait of Sir Philip Sidney, and a gallery of small early portraits from Holbein downwards. Having finished their hasty inspection they proceeded to Sharnbrook, and thence to Felmersham, where they inspected the churches at their leisure, waiting till the rain ceased. Then they made their way to Stevington, where they admired the Anglo-Saxon work in the tower, and also a curious low side-window, perforated through the wall to enable worshippers in the south chancel aisle to see the elevation at the high altar. Some

floriated crosses on stone slabs, formerly the lids of tombs, were also shown. From Stevington they passed to Oakley—a parish almost wholly belonging to the Duke of Bedford, whose pew in the church is partly roofed by an old rood-loft, much of which still stands *in situ*. Here a mixture of Saxon and semi-Norman architecture was noticed by Mr. Parker, who acted as interpreter to the party. The archaeologists drove back to Bedford by way of Bromham-bridge, a curious structure of the 14th or 15th century, which here spans the Ouse and consists of between fifteen and twenty arches. In the evening there was a large gathering at the Assembly Rooms, when papers were read on the "Doomsday-book of Bedfordshire," by Mr. Cary Elwes, and on the "Eminent Families of the County and their Heraldry," by Mr. Stephen Tucker, Somerset Herald.

Monday, the concluding day of the Congress, was in some respects one of the most pleasant of all, being devoted to a visit to Elstow, the birth-place of John Bunyan. The parish-church in which the future author of the "Pilgrim's Progress" was baptised, and which is now undergoing an entire restoration—indeed, to some extent a reconstruction—was visited by the archaeologists, who were somewhat divided in opinion as to the merits of the plan followed by the architect. They also inspected the cottage traditionally said to have been inhabited by Bunyan, and the old "moot house" upon the village green, with the base of the village cross standing near it. From Elstow the drive was short to Houghton Conquest, where the fine, but fast-fading, frescoes on the walls and the tombs of the Conquest family, with their brasses, were much admired. Thence Amptill was reached, where luncheon awaited the party at the White Hart, after a hasty visit to the picturesque ruins of Houghton-house; while some, in preference to luncheon, walked to the cross, erected a century and more ago by Lord Ossory, in Amptill-park, to the memory of Katharine of Arragon, who resided here when her divorce was pronounced by Cranmer at Dunstable, and afterwards was content to live here a disrowned queen. The afternoon was spent by most of the archaeologists in a visit to Wrest-park, where they were shown the fine gallery of family paintings belonging to the De Greys, Cowpers, and Lucases. The weather throughout was delightful, and the congress happily ended without any *contretemps* or drawback.

KENT ARCHEOLOGICAL SOCIETY.

THE annual two days' meeting of this society was held last week, the centre being Canterbury. On the first day (Wednesday) the hospital at East Bridge, in that city, an establishment founded about 1180, was seen under the guidance of Canon Scott Robertson, after which the 24th annual meeting was held in the hospital chapel, when a report of a highly encouraging character was read. It stated that interesting discoveries of foundations containing Roman masonry have been recently made at St. Pancras ruins, in the cemetery of the ancient Abbey of St. Augustine, outside the city of Canterbury. Other discoveries have been made near Canterbury and Wingham by Mr. Dowker, and the fruits of other discoveries made at Faversham and Canterbury will be seen in the temporary museum, where they have been placed by Mr. Brent and Mr. Sheppard. At the Roman castrum of Reculver, the demolition of certain wooden outbuildings has exposed to view a portion of the core of the Roman wall, not before seen. Owing to a slight landslip, this masonry needs to be underpinned. The Admiralty had resolved to underpin it and to face it with new brickwork. Colonel Pasley, the Director of Works, has most kindly ordered that instead of a complete masking-wall, nothing more than piers necessary for support shall be placed over the old wall-core.

The ancient church of St. Martin was next visited, a paper being read there by the Rev. Canon Routledge. He said: "The original church allowed to fall into partial ruin after the Roman evacuation of Britain, was probably restored towards the end of the 6th century, and rededicated to St. Martin of Tours; and portions of this building are existing even in the present day. The church has suffered from frequent partial destructions and restorations. Windows put in at uneven levels, doorways and porches

stopped up here and there, and the irregularity and incongruity of the masonry, all testify to its varied fortunes. A perfect mine of wealth for the geologist is to be found in its wall, including Roman tiles, travertine, tertiary sandstone, Kentish rag, Purbeck, red sandstone, Caen stone, flint, and green sandstone. The interior of the church assumed its present general shape at the end of the 12th or beginning of the 13th century, though many alterations and additions have been made. Of the building as it now stands we may roughly assign the different portions to the following periods:—Roman.—General prevalence of tiles, most likely some of them *in situ*, in parts of the chancel wall. Saxon or pre-Norman.—The Priests' door (6ft. high) on south of church; traces of another door south-east of nave which from measurement I have discovered to be necessarily anterior to the Norman piscina; and large portions of wall masonry—square stones with long intervals of sea-shore mortar. Norman.—Font; probably buttresses; and a piscina said to be the earliest and most complete existing in England, with two holes above it for the support of the canopy. It measures 20in. by 12in. Early English.—Chancel arch, roof of nave, and locked porch or door south-west of the church. 14th century, Decorated.—The lower and single-light windows of nave. Beginning of 15th century.—The window over the font, which is clearly half of a former two-light window. End of the 15th century.—The ambury. Mr. Loftus Brock, F.S.A., Hon. Sec. of the British Archaeological Association, considered the font, which is almost unique, from being built up of different stones in tiers—as of the Saxon period, but subsequently decorated and beautified.

The members next visited the site of St. Pancras' Chapel, so far as it lies in the grounds of the county hospital. Here excavations have been made under the direction of the Bishop of Dover and Canon Routledge, but the owner of the ground on the other side of the wall has refused to allow any digging to take place there. There are still standing, Canon Routledge said, portions of a wall built with Roman tiles and sea-shore mortar, pronounced by Mr. Parker and others to be a Roman wall, with apparent traces of the spring of an arch. The wall is about 9ft. long, and 8ft. high above ground, with buttresses of 16in. and 18in. The foundations of a wall and buttresses, exactly corresponding, have been uncovered on the other side, forming a porch 10ft. 6in. long, and 9ft. 3in. wide, with an opening at the west end of 6ft. 6in. Below the surface, at an average depth of 14in., there are parts of a pavement consisting of coloured and patterned tiles, mostly of the latter end of the 14th or beginning of the 15th century. These tiles have been found in all parts of the building, and some of the earlier ones apparently formed the pavement of that church, of which the east window and chancel walls are still remaining. About 15in. below this pavement are some remarkable tombs, in which were found bones, laid on the bare earth, and built round with stones. On the eastern side of the porch is a doorway 2ft. 8in. wide, of Norman workmanship, splayed internally, and leading into the nave. The walls turn southward for a distance of 12ft. from this doorway, then eastward, till at a little over 16ft. from the turn we come to a slab of Betherden marble, and some 15th-century work forming part of a doorway leading into the southern chapel, aisle, or porch. Then on for 24ft. till we have reached the end of the nave, where we find a lateral buttress extending 3ft. 5in. to the south, and a Mediaeval wall or buttress reaching 6ft. 9in. to the east. Here also is a massive circular pillar, apparently embedded in the wall. The foundations of the old chancel wall, on which that of the later church has not been symmetrically placed, start 10in. further in than those of the nave-wall, and can be traced for 12ft. or 13ft. more till we detect the apparent commencement of an apse; but at this interesting point we are warned off by the owner of the adjacent ground.

There are remains of a rude altar, with the pavement of 15th century tiles, complete on either side. The altar, 4ft. 4in. by 2ft. 2in. in size, is of an uncertain date, possibly cotemporary with the pavement, but built on older foundations. In addition to the later 15th-century doorway there are distinct traces of an entrance 3ft. 3in. wide, on the northern side, 3ft. from either end,

the jambs not splayed, but running straight through at right angles to the walls. Among the debris in this portion were found several pieces of glass and of fused bronze, and portions of a door and Late Tudor window, and deeper down two or three fragments of Roman pottery. Seven or eight inches below the tile pavement, under a close layer of brick earth, is a floor of concrete, showing, in parts, marks of fire. This concrete floor seems to extend beneath the present altar, and is also found just outside the porticus in the nave; and (within the pigstye) at the entrance to the chancel, where we discover something like steps. The foundation walls (20in. wide) are composed of Roman tiles with here and there salmon-coloured mortar, and in other cases mortar made from sea-shells and pebbles and even later material. Canon Routledge added that he conjectured that the remains at the east-end were those of a small Romano-British church, and this was corroborated by a story related by Thorn, a writer who flourished five centuries since. In this view other speakers concurred, Mr. Loftus Brock remarking that it will be a disgrace to the men of Kent if such a place be allowed to remain in its present wretched condition.

The members having been shown over St. Augustine's College buildings, were divided into three parties and conducted over the cathedral by Archdeacon Harrison, and Canons J. C. and W. A. S. Robertson.

After dinner, to which upwards of 200 sat down, an evening meeting was held in the cathedral library, under the presidency of the Dean.

The Rev. Canon Jenkins opened a discussion on the question, "Did Lanfranc introduce close-jointed masonry into England?" and was followed by Archdeacon Harrison, the Rev. Canon W. A. Scott Robertson, and the Dean. The last-named said that close-jointed masonry existed in the time of Lanfranc.

Mr. James Neale, F.S.A., read a paper on the wall-paintings in Canterbury Cathedral, and the means used for their preservation, from which we may give extracts in a future issue.

The second day, Thursday, was devoted to an inspection of several village-churches near Canterbury, the members proceeding in carriages.

At Ickham Church the members were received by the vicar, the Rev. E. Gelder, who showed that the tower was the only discernible relic of the old Roman structure. The north and south walls were pierced at some period in order to throw out aisles; but instead of erecting arcades, portions of the walling were left to support arches of unequal span.

At Wingham Church the Rev. Canon Scott Robertson read a paper on this large edifice, which has fragments of a Norman doorhead outside the west wall of north chancel, and became collegiate in 1286. The church was restored by Mr. Ferrey some years since.

Having seen two Mediaeval houses in Wingham, the members proceeded to inspect the important excavations recently made by Mr. G. Dowker, F.G.S. Having heard reports that Roman coins and carved stones had been found in the parish, Mr. Dowker made trial borings, and had been so fortunate as to find foundations of a Roman villa. He believed, from the great number of Roman tiles, fragments of mosaic, brickwork, and concrete he had found, that the remains of a Roman town would be disinterred here, which would quite eclipse in interest those recently found at Brading, Isle of Wight.

At Adisham a description of the principal features of the church was given by the Rev. H. Montagu Villiers, the rector. On looking round the church he supposed they would agree that it was originally a Norman church, but there was very little of the Norman building left. The nave was that of the second church which belonged to the earliest Pointed period, and was supposed to have been built about 1150. A stained-glass window has been put in the church to the memory of the late Mr. Godfrey Faussett, formerly secretary of the Kent Archaeological Society. On driving to Bifrons, the seat of the Marquis of Conyngham, the members were received by the steward, and were permitted to inspect various rooms which contained many valuable paintings and objects of interest. Patricbourne Church, near Bitons, was described by the Rev. F. T. Vine. He stated that a church existed there in 1086, the name of the place being then simply Bourne. The architec-

tural details led to the belief that the church was rebuilt in the second half of the 12th century. The last restoration was carried out by Sir Gilbert Scott in 1857. The most remarkable feature of the church was the doorway, which was the most richly-moulded Norman one in Kent. At Bishopsbourne Church, a spacious building restored nine years ago, the monument to Richard Hooker—the "judicious Hooker"—who was described as Master of the Temple and for five years rector of this parish, was seen, and a visit to the rectory, where Hooker's study and the dining-room were inspected, closed the proceedings.

BOOKS RECEIVED.

A Practical Treatise on Coach Building, by James W. Burgess (London: Lockwood and Co.), is a contribution to a branch of technical literature singularly barren, so far as good textbooks are concerned. From an antiquarian, as well as a practical point of view, the history of carriages is very interesting, and a somewhat fuller account of the gradual development of vehicles and their parts, from the first rude forms of raft and sledge, down to the shapes with which we are now familiar, than that given in M. Burgess' first chapter would have been welcome. We should also have been glad of more detailed information in the more practical portions of the book.—*The House-owner's Estimator*, by Jas. D. Simon, A.R.I.B.A., edited and revised by F. T. W. Miller, A.R.I.B.A. (London: Lockwood and Co.), is the third edition of a handy, well-compiled, and accurate price-book for unprofessional people, as well as the architect and builder.—*Birchington-on-Sea and its Bungalows*, by Athol Mayhew (London: B. T. Batsford), is a readable account of the well-known village of Hygeia, at Birchington. There is also an appendix on the Island of Thanet and its History, by the Librarian of Lambeth Palace.—*The Forcing Garden*, by Samuel Wood (London: Lockwood and Co.), is by an author well-known to horticulturists by his previously published manuals on kindred subjects. It seems just the book for the amateur who, having mastered amateur gardening in its ordinary branches, is thirsting for new triumphs.—*The A B C of Gothic Architecture*, by John Henry Parker, C.B., &c. (London and Oxford: Parker and Co.), is intended by the author to serve as a stepping-stone to larger works on the subject. It is as simple and easy as possible; a child may understand it, while many a more advanced student may profit by its possession.

CHIPS

Mr. Frank N. Pettingell, of Hull, who has recently prepared a large bird's-eye view of his native town, which is now being published by the issue of chromo-lithographed copies, is at present engaged upon a similar view of Leeds and suburbs. The picture, which is being published in water-colours, is of large dimensions, measuring (exclusive of frame or any accessories) 9ft. by 3ft. 6in.

In a chip relating to the appointment of the retiring surveyor of Bath as consulting surveyor on p. 103, the name should be Mr. Parfitt, and not Mr. Davis, as printed.

An art-treasures exhibition was opened in the Exchange Hall, Banbury, on Monday week. The exhibits are valuable and numerous; the largest number being contributed by the Earl of Jersey.

Iron gates and fencing have just been placed to the public museum at Maidstone. Mr. Hubert Bensted, the architect of the museum, designed the work, which has been carried out by Mr. Wallis and Mr. Shrubsole.

A bust of the late Field-Marshal Viscount Combermere, in the uniform of Colonel of the 1st Life Guards, is about to be placed in the officers' mess-room at Hyde Park barracks; Mr. Theed is the sculptor.

The town council of Margate received last week a report from Captain Douglas Galton, C.B., approving of the drainage-plans prepared by the borough surveyor, Mr. Albert Latham, which have been adopted, subject to the sanction of the Local Government Board.

The police-stations at Neville's Hall, in Ulverston, are being pulled down, to be replaced by a new block of buildings, consisting of superintendent's residence, constables' dwellings, and cells. The entire contract has been taken by Mr. Gradwell, of Barrow-in-Furness.

Building Intelligence.

DROITWICH.—Impney Hall, Droitwich, recently built for Mr. J. Corbet, M.P., is having its internal decoration completed. It is built in the style of a French chateau of the period of Louis XVI., from the designs of M. Iroquois, its erection being superintended by Mr. R. Phené Spiers. The internal decoration is the work of Mr. J. Taylor, of Five Ways, Birmingham. The vestibule is decorated in tints of buff, green, and salmon. In the corridor the walls are of Pompeian red, a green decorated dado extending beneath. The staircase and ceiling are of oak, and the colouring of the walls is of full-toned sap-green. From the corridors, entrance is obtained to the study, an apartment of octagon shape. The flat portions of the ceiling are ornamented with a dark fret pattern on a silver ground, while the panelled cove, enriched with massive mouldings, is more elaborately treated. The panels have central shields, portraying the Arts and Sciences, and from these spring lighter decorations, filling each panel. Beneath, the wall is painted in imitation of tapestry of a reddish tone. The woodwork is of oak, richly carved, and the marble mantelpiece has an oak overmantel reaching to the ceiling. The dining-room measures 35ft. by 22ft., and has a lofty ceiling, with very ornate mouldings. The large central panel is ornamented with a gold-colour diaper pattern on a gold ground, surrounded with belts of silver and colour; while the panels in the spandrels have golden vine-leaves and grapes, upon a ground of neutral grey, surrounded with margins of gold and light maroon. Above the oak dado the walls are painted in imitation of dull grey-green tapestry. The ceiling-mouldings of the drawing-room give a large oval in the centre, about 16ft. by 13ft., treated with an aerial clouded sky, and cherubs carrying flambeaux and strewing flowers. The angle-panels have gold grounds, with cameo-heads of Beethoven, Bach, Handel, and Mozart. In the library the flat of the ceiling is of a full turquoise-blue, with a diaper pattern in silver and gold, the cornice being relieved in red, citron, vellum tint, and gold. The boudoir is panelled with blue silk damask and gold mouldings. The woodwork is of vellum and gold, and the ceiling is painted with flying birds of rich plumage, butterflies, &c., upon an aerial ground. The builder of the hall is Mr. Wood, of Worcester.

ELY.—An extensive group of new schools, erected under a Charity Commissioners' scheme, were opened in Ely on Wednesday week. The new building will be known as Hereward's Hall, and has been erected from the designs of Mr. R. Herbert Carpenter, of London. The style is Late Fourteenth Century. The building is of red Suffolk brick with Bath-stone dressings, and forms, together with the new Theological College, an important addition to the architectural features of the city. It is situated opposite to the Ely Porta, built by Walpole in the 14th century, which is used as a large schoolroom, and stands on the site of the old Pilgrims' Hostelry. It comprises dormitories for 60 additional boys, with library, preparation rooms, private studies, masters' and matrons' rooms, and sick-quarters, with the best modern arrangements, which are now considered suitable for our large public schools. A library and decoration fund has already been started.

HIGHBURY.—On Saturday morning the Bishop of London consecrated a new church situated in Highbury Vale. The new church, which is to be known as St. John's, is a commodious structure of the 14th-Century style, and consists of a nave, transeptal aisles, chancel, and vestry. The building is of stock bricks with Bath stone dressings, and the columns are of Forest of Dean stone. There are also a handsome pulpit, reading-desk, and font, the last being the gift of a member of the church. The building was commenced in July, 1880, and will provide sitting accommodation for about 820 persons.

IPSWICH.—The completion of three important undertakings—a new dock-entrance, a new post-office, and new museum—was celebrated on Wednesday week with public rejoicings and inaugural ceremonies, in which the Right Hon. Joseph Chamberlain, M.P., took part. The new entrance to the wet dock is placed on the south or seaward face of the area, whereas the old

entrance was situate on the east side, opening awkwardly into a narrow channel; the lock is 300ft. long between gates, and 403ft. over all from pier to pier; the width is 50ft., and the depth over sills is 23ft. 6in. 35,000 cubic yards of soil have been excavated, much of which has been utilised in making concrete for the walls, which have been faced with hard bricks; the quays are edged with Bramley Fall stone, and the sills and quoins are of Cornish granite. The frames of gates are of greenwood, and the filling-in of creosoted Baltic fir. Mr. J. F. Bateman, F.R.S., is the engineer, and the contract has been carried out at a cost to the Dock Commissioners of about £45,000, by Messrs. Henry Lee and Son, of Westminster. The post-office, which occupies a prominent position on the Cornhill, is erected from the designs of Mr. John Johnson, of Queen Victoria-street, E.C., which were selected from 22 submitted in competition. The style is Italian, and the details evince considerable refinement. The two chief fronts are of Portland stone, enriched with varied carving, the other side being of local bricks. In front is a portico, on which are four sculptured female figures. The southern portion of the building, separated by a party-wall, is arranged as School Board offices, and rooms for municipal purposes. Messrs. D. C. Jones and Co., of Gloucester, were the contractors, and Mr. G. J. Farrow, the clerk of works; the carving was executed by Mr. Baird, of London, and the sculpture by Mr. Woodington. The cost has been about £10,000. The third enterprise includes the museum, schools of art and science, and free library, these being located in a Queen Anne group of buildings in High-street. They include a central hall 103ft. by 33ft., and north and south wings each about 76ft. by 23ft. The work is carried out in red brick, with terra-cotta dressings. Mr. Horace Cheston, of Great Winchester-street, E.C., is the architect, his design having been selected in competition; Messrs. J. B. and F. Bennett were the builders, and Mr. R. T. Orr the clerk of works; the cost has been about £7,800. The accepted design for the post-office was illustrated in the *BUILDING NEWS* for September 12, 1879, and that for the museum on August 29, 1879, both in Vol. XXXVII.

LLANTISSENT CHURCH.—This church has been renovated throughout, and was reopened on Friday last. The floors have been taken up and relaid on solid beds of concrete, after many old vaults were properly repaired and made safe. The whole of the nave roof has had the barrel-plastered ceiling scraped down, and a fine-sawn 14th century oak roof exposed to view 6in. and 18in. apart from centre to centre, curved and braced. The square stone tower before the restoration was in a tolerably good state of repair, and, with the exception of pointing and re-setting the battlements on the top, and repairs to bell carriages, this has been untouched. Upon removing old pewing and plaster from walls of nave and chancel, an interesting piscina and mural stairs were found. The roofs throughout have been covered with Whitland Abbey slates. A handsome new pulpit has been placed on the north side near the chancel arch, the reading and lesson desks being opposite, the chancel and choir seats properly arranged, and new Communion-rails fixed. The nave has been fitted with red pine open seats. The windows have been filled in with cathedral-coloured glass. The whole of the alterations have been carried out for about £600, the contract being let to Mr. William Blackburne, builder, of Newport, who has carried out the same from plans prepared by Mr. Lansdowne, architect, Newport, Mon.

TYNEMOUTH.—A new memorial reredos has just been placed in the parish church at Tynemouth. Mr. C. H. Fowler, F.S.A., is the architect, and the design is in the Italian style of the 13th century. The centre panel is filled with an elaborately-carved cross, and on either side are niches containing figures of the chief virtues. Below the retable the work is executed in dark alabaster, and the upper portion of white alabaster, the background of the sculpture and other panels being brought out in gold. The work was entrusted to Mr. John Roddis, of Birmingham.

The district of Church Town, St. Buryan's, is about to be drained, from plans prepared by Mr. J. Cardell Thompson, of Penzance.

COMPETITIONS.

GATESHEAD.—At a meeting of the Gateshead Board of Guardians, held on Tuesday, the 19th ult., the designs submitted in open competition by Mr. Wm. Lister Newcombe, F.R.I.B.A., of Newcastle-upon-Tyne, for proposed additions to the Workhouse, Union-lane, were almost unanimously selected as the best, and awarded the first premium.

GLASGOW MUNICIPAL BUILDINGS COMPETITION.—Mr. J. D. Marwick, the Town Clerk of Glasgow, writes as follows:—It may be of interest to those of your readers who intend to send in competitive designs for the new Municipal Buildings for this City to know that the Committee on New Municipal Buildings, acting under full powers from the Town Council, on 11th ult. appointed Mr. Charles Barry, architect, in London, and Mr. John Carrick, City Architect, Glasgow (1) to select from the designs in the preliminary competition those the authors of which shall be invited to compete in the second and final competition; (2) to advise the magistrates and council in the selection of the four best designs submitted in the final competition; and (3) to advise on the probable sufficiency of the estimates submitted by competitors. All in terms of the fourth paragraph of the conditions of preliminary competition.

EDINBURGH.—The competing plans for the new edifice proposed to be erected at Meadow-place, to accommodate the congregation of West St. Giles' Church, Edinburgh, were submitted to Mr. J. McVicar Anderson, hon. secretary to the Royal Institute of British Architects, for his opinion. That gentleman has now reported in favour of the design by Messrs. Hardy and Wight, 7, St. Andrew-square. The style of the building which Mr. Anderson recommends for adoption is Decorated Gothic of the middle period, with a tower and spire rising to a height of 160ft., the spire springing from a parapet with flying buttresses. The interior is spacious, and shows a nave, aisles, and transepts, the arcade resting upon polished columns of red granite. There is an open roof to the collar-beam, 46ft. in height, with transept and end galleries seated for about 300 people, the entire accommodation being for 1,000 persons. Space is allowed for an organ in the apsis behind the pulpit. The church as designed will not cost more than £7,000.

WALMSLEY.—At a vestry meeting held on Wednesday week, to consider the proposal of building new schools in connection with Walmsley Church, sketches submitted by Mr. John Morris, of Wood-street, and Mr. Marshall Robinson, of Acresfield, were examined. The committee unanimously voted the adoption of the designs by Mr. Robinson, who was instructed to proceed with the work at once.

CHIPS.

New wards and a disinfecting shed are about to be built at the Derby Union Workhouse; Mr. Edward Fryer, of Albert-street, Derby, is the architect.

A parish-room is being built at St. Luke's, South Lyncombe, near Bath. The architects are Messrs. Gill and Brown, and the contractor is Mr. T. Laver.

A fine-arts loan exhibition was opened at Canterbury by the mayor of that city on Monday. It is being held in the Foresters' Hall, and appears to be very successful. The Marquis of Conyngham has lent some of his art-treasures from Biffons, including works by Murillo, Rembrandt, Holbein, and Watteau, and a collection of armour and weapons; a large number of paintings and engravings, and of specimens of china, bronze, and other exhibits, are on view.

The organ in St. Mary Redcliffe Church, Bristol, has just been reopened, after extensive enlargement and alterations, carried out by Mr. W. Fowles, of Bristol.

A stained-glass window has been placed in the south aisle of St. John's church, Margate, as a memorial. The window is of two lights, and forms part of a scheme illustrating the Beatitudes; Messrs. Clayton and Bell, of Regent-street, London, carried out the work.

A new Presbyterian church was opened on Friday at Donore, near Dublin.

St. Broock Church, West Cornwall, was reopened on Tuesday week, after having been restored at a cost of £1,400.

"To a practical man with a taste for mechanics, and the bumps of inventiveness fairly well developed, we can conceive no higher mental treat than a couple of hours spent over the June numbers of that truly marvellous publication the *Engineering*. In a hundred and fifty odd pages that make up the bulky mass of letterpress, there is recondite information on almost every conceivable subject, ranging from how to construct a mouse-trap, to the latest method of calculating the phases of Orion."—*The Bookman*. Price Two-pence of all newsmen, or post free 3d.—J. TAVISTOCK STREET, COVENT GARDEN, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 6s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is ONE SHILLING for TWENTY WORDS, and sixpence for every eight words after. All situation advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in serial advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33s. 30c.). To India (via Brindisi), £1 10s. 10d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

MR. CHARLES WILSON, of 13 and 15, Lighthouse-street, New York City, is authorised to receive American subscriptions at the rate of 6 dols. 40c. per annum.

MR. R. M. TUTTLE, of Titusville, Penn., U.S.A., is also authorised to receive subscriptions at the same rate.

Cases for binding the half-yearly volumes, 2s. each.

NOTICE.

Now Ready.

Vol. XL, Price 12s. A few bound volumes of Vol. XXXIX. may still be had, price Twelve Shillings; all the other volumes are out of print. Most of the back numbers of former volumes are, however, to be had. Subscribers requiring any back numbers to complete vol. just ended should order at once, as many of them soon run out of print.

Correspondence.

FRESH-AIR VENTILATION.

To the Editor of the BUILDING NEWS.

SIR,—Will you kindly allow me to refer to Mr. Michael Drury's letters in your issues of the 15th and 29th inst. Can that gentleman be really in earnest when he so strongly advocates the use of *fin.* air-pipes to take off sewage-gas and to protect traps from siphonage? If so, I can only conclude that he has not studied the subject much.

I have tried both small and large air-pipes, and my experience teaches me that to properly protect the seal of a trap from either siphonage or waving, the vent-pipe must be of a size proportionate to the demand for air likely to be made upon it. I once tried the following as an experiment: I had 20ft. of *lin.* air-pipe, taken from the dome of a siphon-trap, fixed below an improved hopper basin. On pouring in a pail of water the seal went out level with the tongue, and virtually untrapped it. I then took out the *lin.* air-pipe, and inserted a 2in. of same length, and then again poured in a pail of water, which had no effect upon the seal. Since that experiment, which I carried out in 1879, I have fixed scores of vent-pipes, and am firmly convinced that a *fin.* one is only a little better than nothing. Mr. D. says that "Stiff's Interceptor will not, of itself, prevent the siphon-action of a trap." There Mr. D. is quite right; the fact is, that an opening at the foot of the soil-pipe, or in the drain, greatly facilitates siphon-action,

thereby necessitating the use of a larger vent-pipe than would otherwise be required. My own practice is to carry up the soil-pipe full-bore, and to take a 2in. or 3in. (according to circumstances) vent from the trap, both of which I consider necessary.—I am, &c.,

DANIEL KNITAGE, S.E.,
Dane-hill Sanitary Works, Margate,
July 30th, 1881.

SIR,—The letter from Mr. Michael Drury, of Lincoln, at page 154, shows that a real sanitary genius has sprung up amongst us—one, too, whose scientific attainments are only equalled by his financial enunciations. Let us examine him!

He says the extra cost, when fitting up the soil-pipe, of putting in a ventilating-trap at its foot, and an exhaust-cowl with ventilating pipe upon its top, will "exceed £10." Now, suppose we calculate it: Cowl, for 4in. pipe, 25s.; pipe, about 11s. (This item will vary, more or less, and, regarding the trap, I may ask—Does Mr. Drury dispense with fireclay or such-like traps between the sewer and the soil-pipe?) Trap, say, 10s.; air-grating and fixture, say, 6s.; and add 5s. for sundries—in all about £3—not *one-third* of what Mr. Drury says!

He also writes as if the putting in of a small *fin.* compo. air-pipe upon the top of a soil-pipe "without a fresh air method (or inlet) will effectually prevent any accumulation" of bad air. Now, will he tell us how the bad air that will be generated in the soil-pipe, only open at the top, is to be prevented from accumulating? He does not seem to know that it is the fresh-air coming in at the bottom of a ventilated soil-pipe continually pushing or carrying away the bad air as it is generated, that prevents "accumulation."

A soil-pipe open only at the top (and all the more with only a *fin.* opening) is *not* ventilated. It is continually full of bad air, which bad air is ever active and ready for mischief against the inmates at the first chance. Mr. Drury's plan may be compared to a steam-boiler without a safety-valve. The furnaceman may boast that such valves are superfluous, and to show his faith in his ideas, he takes dinner every day seated upon the lever. The steam, however, bides its time, and upon an unlucky day something happens, followed by a coroner's inquest.

In closing, I may sum up Mr. Drury's letter as a simple confession that he has been executing his plumbing-work in a very inferior manner, and whether to blame him or the Lincoln authorities most, is a question I shall leave to higher authorities to decide.—I am, &c.,

W. P. BUCHAN.

Glasgow, July 30th.

VENTILATION OF SOIL-PIPES.

SIR,—Mr. Buchan in his letter, p. 153, B.N., states that he had "seen the letting-off of a Bramah closet *suck* the water out of a bath-trap 12ft. from it, even when the said bath-trap had a 2in. air-pipe"; without impugnig the veracity of the statement, I cannot help thinking that there is some mistake. To me, it appears literally *impossible* that water should be *sucked* out of any S-pipe which has any kind of orifice in the apex of the bend; any "sucking" influence must inevitably operate upon the orifice and the non-resistant atmospheric air, instead of affecting the comparatively ponderous water-seal of the trap.

Mr. B. further states that the *fin.* compo tube recommended by me, "helps to prevent concentration of the sewage gas at the top of the pipe." If it does that, it does everything. If concentration is prevented, the most important and the only essential part of sewer ventilation is secured. The "top of the pipe," or what I should call the "trap apex," is exactly that spot, and the *only* spot, whence sewer gas can possibly penetrate into the house and become offensive and unsafe. The natural tendency of sewer gas to concentrate, or rather accumulate, at this "trap apex" is the motive power which compels it to pass through the easy route of the outlet-pipe, rather than force its way through the difficult, fortified obstacle of the water-seal. It is of little practical import whether the outlet or vent-pipe is 2in., 4in., or *fin.* bore, or whether it is thin compo, or thick lead, or massive iron tubing, so long as the vent-pipe is intact throughout to its outlet. It matters not if it bends here and there or anywhere, so long as it

has an upward tendency and has an open road, and it is not fair to stigmatise anything as "cut and run" or "scamping" work, simply because it is economical. I have no patent rights for anyone to infringe, and, therefore, I take the trouble of writing on these matters on purely public grounds. For the present, I need not refer to other portions of the letter which are open to criticism, but will content myself with calling the attention of your readers to Mr. Buchan's remarkable and converted condemnation of "revolving" cowl. There is *some good* in *nearly all* the patent complications, and whilst "damning them with faint praise," allow me still to maintain that they are "superfluities," or at the best, "luxuries."—I am, &c.,

MICHAEL DRURY.

COOPER'S HILL COLLEGE & THE ROYAL ENGINEERS.

SIR,—I can corroborate some of the statements of your correspondent, Mr. Playfair, from having been in India during the time of the unfortunate failure of the Sagar Barracks. It is difficult for an engineer accustomed to works in England, and who has never been in India, to realise the state of blundering and incapacity exhibited in conducting works in that country. If a wall or an arch is built under the supervision of an official, it is almost certain to crack. If a roof is erected it will leak like a sieve. If a bridge is constructed it is almost certain to fail before long, like that over the river Kantran, near Nagpore, which was founded on sand, with the rock a few feet below, on which it might have been erected with safety. Sometimes this blundering leads to loss of life, as on the failure of the Gun-Carriage Factory at Allahabad.

There was the Lawrence Asylum, which was proposed by the Madras Government in 1864, and estimated to cost £18,000, but which had reached, in 1870, the enormous sum of £118,000, and drew the censure of the Government on the architect and two engineer-officers. Again there was the Government House at Poona, sanctioned by the Bombay Government on the express understanding that the cost was not to exceed £35,000, but which ultimately rose, before the work was completed, to £155,000.

The Royal Engineers have the ear of the authorities, and can represent things as they please without risk of contradiction, and probably the Duke of Argyll was induced to believe that all these failures and imperfections were due to the employment of civil engineers. If civil engineers were employed it must have been in a very subordinate capacity, and their work must have been inspected and approved by Royal Engineers, who at that time occupied every post of importance in the Public Works Department. To say the least of it, there is meanness, if not dishonesty, when failures occur, to endeavour to saddle subordinates with a responsibility that they would not have been accredited with had the work proved a success, and which really belonged to the superior officer, almost invariably a Royal Engineer, who inspected and approved of the work. If District Superintending Royal Engineers cannot secure the Government against the imperfections of subordinates, their office is a delusion and a snare.

Poor Supervisor Bartram, at Allahabad, was made to appear a very great delinquent indeed, and, I believe, was dismissed from the Public Works Department, while much milder measures were dealt out to those who, from their supposed possession of superior knowledge, were really the persons who should have looked after the work as well as after Mr. Bartram.

There are very able and intelligent men I have no doubt in the Royal Engineers, but they do not appear to possess much practical knowledge or aptitude for ordinary engineering work. Their training fits them more for laying out boundaries between hostile nations or preparing projects for the defence of States, than for studying the details involved in the foundations of a building or the erection of a bridge, which they leave to subordinates of very indifferent acquirements, rather than acknowledge their own inefficiency, by employing persons of superior attainments.

That the defect is in the training of the Royal Engineers, rather than in any peculiarity connected with India in reference to the works of the same body of men in England, where they have it all to themselves, will show. Witness the following, taken from the *Standard*, of January 15th, 1875.

"Two out of three extensive traverses recently completed by the Royal Engineers, with entirely new brickwork at Fort Burgoyne, at Dover, have fallen to the ground."

This was attributed by the Royal Engineers to the action of frost. As if it were not the duty of an engineer to provide against contingencies of that kind, if it were true, which is doubtful.

We have a similar instance from the *Daily News* of January 1st, 1879, when a wall at Dundee Barracks fell, owing to the subsiding of the foundation caused (as stated) by wet weather.

The time cannot long be delayed until the whole question of the Royal Engineers and their mode of conducting works will be the subject of a Parliamentary inquiry, when probably many important facts will be brought to light.

As to Cooper's Hill College, its establishment was submitted to by the Royal Engineers, as a counter-move against the employment of highly-trained Civil Engineers, who would have placed them in the shade with the Government of India. It was not necessary at the time, as Trinity College, Dublin, the Queen's Colleges, Ireland; Glasgow College, and University College, London, were quite equal to the theoretical training required of an Engineer, and are much superior to Woolwich Academy.—I am, &c.,

JAALAM SMITH.

Ryde, I.W., 30th July, 1881.

SANITARY PLUMBING AND PLUMBERS' WORK.

SIR,—In reply to a letter in your last week's issue signed "H. B.," wherein he taxes me with saying that it is always in the joints, and not in the body of the lead, that the leakage occurs, I am not aware that in any of my criticisms on Mr. Hellyer's lectures that I have written anything of the kind, and if "H. B." will refer to my letter, page 57, column 2, last paragraph, he will find I have explained the cause of the corrosion and decay of the lead by the action of the acids, and also stated as my opinion that to prevent this decay every lead-trap (not excepting the \odot or \oslash -trap) should certainly be well ventilated.

If "H. B." was present at the lecture when I was invited to ten minutes' discussion, and is not troubled with a bad memory, he will perhaps be able to remember that directly I commenced to speak I was interrupted by Mr. Hellyer, and that, too, repeatedly. I nevertheless said all I wanted to say—viz., "That when Bramah's own people fixed his closets, although they had a small \oslash -trap attached to the overflow-pipe, they always fixed under the closet a \odot -trap to protect the \oslash -trap and closet at the same time, Bramah knowing that the \oslash -trap alone was not efficient. It is true that there is no \odot -trap in Bramah's specification; but why? Because he was not patenting anything but the closet, and not the trap: he might as well have added a plan of the whole of the drains."

In future I shall not answer any letters signed only with "initials or assumed names," as however much it may be the custom to write to the papers in this manner, I cannot look upon such communications as anything better than anonymous letters.—I am, &c.

P. J. DAVIES, Hon. Mem. A.S.P.

Aston—the great suburb of Birmingham, with a population of 75,000—was the scene of a rather interesting School-Board election last week. The Board, whose term of office has just expired, have built several sets of schools, at a cost of about £100,000, finding accommodation for 8,000 children. A party calling themselves "The Ratepayers' Union" declared the Board had been suffering from "architectural madness," and with a view to stopping such "extravagance" in future, brought out a set of "economical" candidates, who, however, were rejected to a man. Amongst the successful "party of progress" are an architect and a sculptor: Mr. George Ingall and Mr. John Roddis.

Part of the workmen, to the number of 75, of Thos. C. Halliday and Sons, builders, &c., of Greetham, Oakham, and Stamford, spent a very agreeable day at their annual outing (near to one of their works) at Balmisthorpe, on Saturday last, in a field kindly lent by Mr. Hind, and although the day was wet and unfavourable, the greatest harmony and good-will prevailed, every one thoroughly enjoying themselves—a good substantial tent, beautifully decorated, a band of music, and the best of cheer, and every requisite for a day's recreation and pleasure being provided.

Intercommunication.

QUESTIONS.

[6598].—**Royal Engineers.**—Could any of your readers oblige me with a description of the duties of a Royal Engineer, along with the advantages, examinations, &c., required before entering?—J. C.

[6599].—**Decoration.**—I should like to know whether it is more correct for the coloured ceiling of a room to contrast with the walls, or to be of the same shade?—ESQUIER.

[6600].—**Annealed Glass.**—Can any of your readers inform me if this material is applicable for coiling purposes, and where can it be procured?—TALBOT.

[6601].—**Flow of Water.**—Will some correspondent kindly inform me the quantity of water per minute that will pass through a square tube 12 in. by 2 in. (two), having a fall of 1 in 20, and how ascertained?—R. P.

[6602].—**Architecture or Building Trade in Colonies.**—What English-speaking colony is best as offering prospects to the young architect at the present time, and how do the colonies stand as to prospects compared with England? Agents' pamphlets seem all to one purpose—that place being one which the book treats. Possibly some returned or visiting colonist will give us some information of the kind I ask. For myself I speak as one fully intending to clear out unless prospects brighten here, and while I would prefer to work as I have hitherto, that is, in connection with architecture, still, if need be, I could "turn my hand" to kindred arts or to the bench. Information as to building trade generally in colonies would oblige.—FLECK-DE-LIS.

[6603].—**Additions.**—I would ask your readers' opinion on the following:—A builder competes for and obtains a contract to erect some Board-schools. Whilst the works are in progress certain necessary additions are ordered by the architect. When the account, which has been passed by the architect, is presented to the Board they refuse to pay for these extras, and hold to their refusal by a clause in specification which says, "No alteration or addition to be made in these works without the sanction of the Board." Another clause after the above says, "All matters of dispute that may arise between contractor to be referred to Mr. D— of C—, whose decision is to be final." The contractor demands the decision of referee, but the Board will give him no authority to proceed, and the auditor refuses to pass account. (1) Can I, by virtue of 2nd clause, legally recover the amount which referee allows? (2) Does the fact of the Board giving the referee no authority disqualify him before a court of law? Shall be glad to hear opinions on the case through your journal.—TALBOT.

[6604].—**Ice-House.**—In designing an ice-house, 30 ft. by 20 ft. by 25 ft. for above, I would like to have the benefit of your valuable "Intercommunication." I have had the experience of what is termed the "wood and sawdust cushion." What I wish to know is how the air-cushion works, and how best constructed? What is the best way of constructing the walls to insure the desired end? I have been thinking of building a 9 in. external wall in brickwork, and an inner 6 in. concrete wall, leaving an air-space between. Can any of your correspondents say the best way of doing this, and if it would be effective? Also best way of bonding walls together? What air-space should be left, and what ventilation is necessary? The building will be in a town, and floor on level with street. Any information will be acceptable as regards other methods or details. What is the best plan? Are there any authorities on the subject?—T. O. W. N.

[6605].—**Patent Laws.**—Would some reader kindly refer me to a good work on the patent laws? A digest would be preferable, or perhaps through the medium of the *Building News* he would kindly give a sketch of the procedure.—B.

[6606].—**Coloured Plaster.**—I am wishing to make the plastering between timbers of a half-timbered house I am building a reddish tint when finished. What materials could be mixed with the ground lime setting stuff to produce this, or any other tints?—Q. E. D.

[6607].—**Disintegration of Lime.**—Some two years ago I used for building purposes mortar mixed in the following proportions:—Best mountain lime, 1; sand (sharp), 1; red burnt ashes, 2. The ashes were of seagrass or fire-clay from an adjoining colliery, which, being partly mixed with coal, had taken fire and been thoroughly well burned on the pit heap. They were as hard as furnace scales or slag, and in every respect appeared excellent material for the purpose. The effect has been that the lime, wherever they were used, is now entirely disintegrated and useless, but lime in the same buildings, and of the same mixture, excepting that blackashes were used instead of red, is set well, and is in all respects satisfactory. What is the chemical explanation of this? Have the ashes killed the lime, or has the lime, in disintegrating the ashes, killed itself? I shall be glad of some explanation.—C. C. C. E.

REPLIES.

[6552].—**Thickness of Piers of Arches.**—"J. H. M." is correct generally in assuming that the thickness of piers should be increased with their height. There must however be a limit to this, since with the increase of height, the horizontal thrust diminishes whilst the vertical increases, owing to the greater weight of the higher pier, which assists in nullifying the horizontal thrust.—HUGH McLACHLAN.

[6553].—**Veneering Round Column.**—After preparing the column, cut the veneer sufficiently wide to go round it, with an inch to spare. "Tooth" all the saw-marks out both sides. (If it is knife-cut veneer this will not be necessary.) Wet one side and glue the other well with thick glue, or the water afterwards used soaking through would make it too thin. Glue the column also, and fold the veneer carefully round it. Nail on a length of webbing at one end, and roll it round as tight as possible, allowing the edge to overlap about a quarter of an inch all the way. When it is all covered secure the other end of webbing to the column. It must

now be soaked well with hot water and a hot iron passed over it until all the glue inside is thoroughly heated; the shrinking of the web will then force out the glue. After standing eight or nine hours the webbing must be taken off, and with a thin sharp chisel and a straight-edge make a cut down the length of the column, severing the two thicknesses of veneer where the one overlaps the other, then with hot iron and water loosen the veneer at each side of the cut. You will then be able to remove the two strips (the overlapping part). Rub some more glue under the veneer, and put it down with a veneering hammer, or a narrow "call" made to fit. It may be done another way. Prepare glue and place the veneer as before; then, instead of webbing take a strip of strong canvas an inch or so less in width than the circumference of column, and long enough to reach from end to end. Firmly secure each edge to strips of wood. Fold the canvas round the column and veneer so that the two strips of wood almost meet, the joint in veneer being between them. With handscrews, draw the strips together, then wet and heat the canvas. Increase the pressure on screws, let it stand eight or nine hours, and work the joint as before.—W. E. GAUDIE.

[6553].—**Durer's Works.**—In addition to the works mentioned by "East Anglian" and Hugh McLachlan, as having been published in the *Building News*, "Christ taking leave of His Mother" was published on March 17th, 1871.—JAMES ROBINSON.

[6555].—**Smoky Chimney.**—The causes of smoky chimneys are so numerous, that without knowing all the circumstances of the case, it is impossible that an efficient cure could be at once hit on. The chief causes generally are draught, choking or stoppage of the flue, too large a chimney opening or too short length of flue for its sectional area. Each of these may again have several other causes, and these have as a rule their separate remedies. The choking or stoppage of a flue is generally discovered and remedied by the sweep, though occasionally the bricklayer may be required. The chimney opening is unlikely to be too large in a third-floor office; therefore it is probable that the reason of the smoking in this case is either draught or too short a flue. If the flue is too short, the remedy of course is to add some lengths of zinc piping, but such may often be avoided, and certainly should be the last thing to be tried. Draught generally proceeds from two causes: either a want of ventilation for the room, in which case the flue becomes a fresh air down-shaft, or the overtopping of the flue by some neighbouring building or chimney from which the wind rebounds down the lower chimney after striking against the taller object when in certain directions. In the first of these two cases, whether your own fire is lit or not, the air is drawn down your flue into the room, bringing smoke with it from another flue often in the same stack, sometimes even after the smoke has escaped from the mouth of that flue, or through some faulty opening in the flue itself. Opening a window will be found a remedy, and as this can not be done permanently, fresh air inlets should be made through the walls. In the second case the best remedy is unfortunately a hindrance to sweeping, as it requires a cover over the chimney top, the simplest method I have seen in Holland, it consists in bending round a pipe so as to have the opening underneath and turned away from the higher building that causes the draught thus. It cannot well be applied in England for reason before given, or where coal is burnt. Boyle's or Milburn's cowls would probably be effective, the first is not half the cost of the latter and has no movable parts, both profess to give no hindrance to sweeping, which I hardly think correct, the second would probably be best of the two in that respect. A plan recommended in the *Builder*, May 2, 1863, consists in using a blower of fine wire gauze, 35 or 40 meshes to the inch as a blower in front of the fire, this checks the smoke

in a manner similar to the checking of mine gas in the Davy safety lamp. The best paper I have seen on the subject was read before the Irish Architectural Association by Mr. George Heghan, and reported in *Building News*, Aug. 4, 1873, it is called "Construction of Chimneys." If "Draught" is still in doubt, he can call on me at 45, Fenchurch-street.—HUGH McLACHLAN.

[6570].—**Local Board Office.**—Hampstead Vestry Hall, plans and perspective, published in *Building News*, Nov. 15, 1878; vestry halls at Wandsworth and Ealing and Greenwich Board Offices. Some of the above might give hints.—HUGH McLACHLAN.

[6576].—**R. A.—Surely "Jacobus" is joking.** Does he know that the Academicians and Associates are selected from the leading painters, architects, sculptors, and engravers, not by examination but by election? If he further knows that there are only four Academicians and two Associates architects and that probably there are at least 3,000 architects practising in Britain, he can imagine his chance of obtaining the result of his ambition.—HUGH McLACHLAN.

[6576].—**How to Obtain the "Degree" of R. A.**—In reply to "Jacobus," I regret that no certain method can be pointed out. A money qualification is, of course, indispensable. Connections in "society" may do much; but even with these, you must either be a man of some real ability, or must have built a house for some influential Academician.—Z. Z.

[The query was misprinted. It should, of course, have been how to obtain the degree of "M. A."—Ed.]

[6585].—**Soil-Pipe.**—"East Suffolk" will find a drawing of a disconnected soil pipe, with its discharging end exposed to the atmosphere, in the *Building News* for November 17th, 1874. Other drawings have been published since then in these columns, while in Buchanan's "Plumbing," and in Hellyer's "The Plumber and Sanitary Houses," various plans will be found. "Exposed to the atmosphere" does not mean exposed to view.—PETER SIMPLE.

[6586].—**Testing Iron Girders.**—For the benefit of "Learner," I herewith give some particulars of iron girders which I tested on the 5th ultimo at a manufac-

turer's yard in Lambeth. The said girders were four of the longest span of a series of fifty-four girders. They were tested in pairs in the order enumerated in the certificate. The girders are laid on their sides on the ground and held together by pieces of flat bar iron, the hydraulic press being exactly in the centre of and between the two girders to be tested. The space between the two girders is then marked upon a straight edge that the deflection may be correctly gauged. This, of course, is taken when the full pressure is upon the metal. After this the pressure is withdrawn, and if the girder remains deflected it constitutes what is known as a "Permanent set." If it does not remain deflected but springs back again to its original straight form, then there is no "permanent set."

COPY OF CERTIFICATE OF TESTING, JULY 5TH, 1881.

Section.	Span.	Deflection.	Perma- nent set.	Proof Weight.
Two 10 x 6 rolled joists, with two 1/2 plates riveted to top flanges, and one 1/2 plate riveted to bottom flanges of joists 1/2 plate 12 1/2 wide.	19' 3"	1 1/2 in. in.	None	11 tons
	19' 7 1/2"	2 1/2 in. in.	None	11 tons

REMARKS.—A pressure equivalent to half the safe distributed load, viz., 14 tons, that these girders are designed to carry was brought to bear on the centre of each girder by means of hydraulic pressure. Weight per foot run of these girders = 174 lb., thus—joists each 56 lb., plates each 2 lb., rivets 2 lb. per foot run.—ALFRED C. HURLEY.

PARLIAMENTARY NOTES.

IMPROVEMENTS IN WESTMINSTER.—In the House of Lords last Friday, Lord Lamington asked whether, before coming to any determination as to the contemplated improvement near St. Margaret's, Her Majesty's Government would not consider how far it was desirable to carry out the recommendations of the Committee on Public Buildings of 1878. He characterised the approach to the Houses of Parliament through Parliament-street as a disgrace to the great metropolis. Lord Kimberley said this question of the approaches to the Houses of Parliament had been under the consideration of four or five successive Governments and was under the consideration of the present Government; and he had no doubt that before long they would have to decide on a scheme.

WATER SUPPLY OF LONDON.—The Bishop of London asked whether any measures had been taken or were in preparation by Her Majesty's Government for improving the water supply of the metropolis. The right rev. prelate pointed out that in the north-west, south-west, and west of London, where there were many streets of large houses filled with lodger-tenants, the supply was very deficient, limited as it often was to a flow into a cistern or water-butt for an hour, or, perhaps, half-an-hour, each day.—Lord Dalhousie said it had been the intention of the Government to introduce this Session a measure on this subject, but the state of public business had made it impossible for them to do so. They would, however, endeavour to deal with the question next Session.—Lord Fortescue expressed his regret that action had not been taken in the matter before now.—Lord Red-sdale thought that much of the fault of the insufficient supply was chargeable to the owners of houses, who did not provide sufficient appliances for taking and storing the water.

CHIPS.

The parish-church of Swanton Novers, Norfolk, was reopened on the 23rd ult., after restoration, including the addition of a new aisle. During the progress of the work, many traces of Saxon and very Early Norman work were discovered, including a rude doorway, and two small circular double-splayed windows, in one of which the old oak shutter was still preserved; and in the tower an oven for baking the sacramental wafers. A piscina of Decorated character, and other 14th-century work were found embedded in the south wall of chancel. Mr. E. Dolby, of Abingdon, was the architect, and Mr. Chapman, of Ilanworth, the builder.

The work of constructing the Hundred of Illoo Railway is being rapidly pushed forward by the South Eastern Railway Company. The new line extends from the North Kent system at Stoke-ly-Gravesend, to a pier in the Isle of Grain, opposite Queenborough; it is six miles in length, and is estimated to cost £225,000. Messrs. Walker and Son are the contractors.

At a meeting last week of the Penzance rural sanitary authority, Mr. Dennis, C.E., was instructed to prepare plans and estimates for a water supply for Marazion.

LEGAL INTELLIGENCE.

THE REBUILDING OF ST. PETER'S CHURCH, PLYMOUTH.—GUY V. PRYNNE (S.I.).—Mr. Charles, Q.C., and Mr. Pitt-Lewis were counsel for the plaintiff (instructed by Ingram and Co.), and Mr. Collins, Q.C., and Mr. Bucknill (instructed by Mr. Shelley) were counsel for the defence. Mr. Charles, in opening the case, stated that the plaintiff was an architect and contractor, and the defendant was an architect only. The action was brought to recover possession of a document which was known in the profession as a "correct summary." This document the plaintiff lent to the defendant in November, 1880, and had never succeeded in getting it back. The jury would, no doubt, think it very strange that it should be necessary or worth while to institute legal proceedings for the recovery of a simple document; but when the jury came to see the effect of the document, they would readily understand the importance which the plaintiff placed upon it. Why on earth the defendant had refused to return the piece of paper he failed to appreciate. It had been applied for over and over again, but it had never been returned. It appeared that the plaintiff was at present engaged in carrying out a contract for the almost entire rebuilding of St. Peter's Church, Plymouth, a church of which the father of the defendant was the incumbent. The contract was for the entire rebuilding of Mr. Prynne's church for the sum of £9,780. The defendant was the architect who was looking after the work on the part of the employer, his father. The contract was entered into in February, 1880, and the contract itself, as originally drawn, did not contain any stipulation that the surveyor's fees should be paid by the contractor. In such cases, unless the fees were paid by the contractor, they would fall on the employer. The contract contained no provision that the surveyor's fees should be paid by the contractor. Unless these fees were payable by the contractor they would fall on the employer, the Rev. G. R. Prynne. Before it was signed the defendant wrote into the contract a clause that the surveyor's fees should be paid by the contractor. The plaintiff agreed to the insertion of the clause provided the contract-money allowed the demand. If it did not, the defendant assured him that if he had actually paid the surveyor's fees they would be repaid to him. On September 9th, 1880, the defendant sent the plaintiff four documents. One of these documents was the one in dispute, which contained, in figures, the amounts which were to be paid under the original contract. It also showed the addenda which were to be paid by the Rev. G. R. Prynne to plaintiff, and one of these amounts was for the sum of £229, being the surveyor's fees, which, as they would learn, plaintiff paid the surveyor. Of course, it would not have been wise for plaintiff to have paid the surveyor unless he procured some guarantee from defendant's hands. But as soon as he got this paper, which was duly signed by the defendant, and authorised him to make the payment, plaintiff paid the surveyor. Shortly after plaintiff met defendant in the streets of Plymouth, and asked him to lend him the document, which defendant held as a voucher, and as conclusive evidence that he was entitled to claim this money for the payment of surveyor's fees; plaintiff ultimately did lend the document to the defendant. Upon one excuse and then upon another the document had never been returned. After repeated correspondence and several conversations, defendant sent plaintiff a paper, which was not the original paper. It was a copy of the original, with, however, material additions. The importance of this document to the plaintiff they would realise when he told them that the work in the rebuilding of St. Peter's was not proceeding very harmoniously, and the consequence would be that, in all probability, when the contract was brought to a completion, the plaintiff would be obliged to resort to legal proceedings. The words which defendant wrote were "Entirely without prejudice, and to be returned to the architect when required." The addition of these words, of course, deprived the document of any force, and made it a very different instrument from what the plaintiff originally held. The contract only allowed £90 for the surveyor, although it stipulated that he should receive £200. All the plaintiff wanted was to receive back the paper. Mr. Collins: We have offered to give him the paper, I am instructed. Mr. Charles: You have offered us one which does not bear Mr. Prynne's signature, and is therefore no guarantee. This Mr. Prynne seems to be a very strange sort of person, and may dispute the payment of the surveyor's fees. His Lordship: But the plaintiff is entitled to sue for their recovery without any document. He is the contractor of the works, and has the right to pay the surveyor and charge the payment to the person who employs him. Mr. Charles: I feel some difficulty in proving our damage. His Lordship: So I should think. Mr. Charles: It's quite clear that the defendant attaches much importance to this document, otherwise he would never have done what he has done. His Lordship: Is the contract

for a lump sum? Mr. Charles: But it does not include the surveyor's fees. The plaintiff, on being called, said he valued the paper because the contract was so binding that if he did not produce a written voucher he could not sue for addenda. He lent the paper to the defendant on his faithfully promising to return it. Mr. Collins, in defence, remarked that he had never before known an action brought and counsel employed to recover possession of a paper. Defendant appeared to apprehend that there would be a quarrel, and wanted some paper, under the signature of Mr. Prynne. But Mr. Prynne's case was that he never supplied him with a signed paper. Mr. Prynne, on being called, stated that the paper he lent the plaintiff was the unsigned original; and when he desired to get it back he made a copy of it, to which he put his signature and added the words, "without prejudice." His Lordship could not understand what the plaintiff wanted other than the paper which Mr. Prynne supplied him. It was true the words without prejudice were written there, but if an action should be brought for the recovery of the surveyor's fees from the incumbent, any judge would strike them out. The plaintiff was entitled to recover the surveyor's fees by law. Mr. Charles replied that what the plaintiff wanted was an unequivocal document, to the effect that the defendant was responsible, and not himself, for those fees. His Lordship described the case as the most extraordinary he had ever known. He could not imagine what in the world induced the plaintiff to bring such an action. It was for the jury to decide, of course, but he could not help thinking that the plaintiff had made a great mistake. He was clearly entitled to the surveyor's fees, without any such document as he demanded, as the contract stipulated that they should be paid him. The jury returned a verdict for the defendant, and his Lordship certified for a special jury.

STAINED GLASS.

EDINBURGH.—The large central window situated in the south wall of the Preston Aisle of St. Giles' Cathedral has been filled in with stained glass, the design being illustrative of the life of St. Paul. The window is of large proportions, measuring fully 25 ft. in height by 12 ft. in width, and consists of ten compartments, in addition to the flowing tracery above. The two conspicuous events in the life of St. Paul are depicted—his conversion on the way to Damascus, and his preaching at Athens. The upper panels are devoted to the former, and the lower panels to the latter, artistically grouped in five sections each. The work has been designed and executed by the Messrs. Ballantine, under the honorary superintendence of Mr. Robert Herdman, R.S.A.

CHIPS.

An empty house in South-street, Southwark-square, fell into the road on Monday week, severely injuring three children, one of whom has since died from the effects of the accident. At the inquest Mr. Thomas R. Smith, district surveyor for St. George's, Southwark, stated that his attention had been called before the accident to the adjacent houses, but not to the one which fell, which consisted of but two stories; all the lower doors and windows were boarded up, and it was shut in by a high boarding. The bricks were sound, but the mortar had perished, and the roof had been injured by the theft of lead. He attributed the accident to the transmission of vibration from the railway arches to the roof of the house. On behalf of the Ecclesiastical Commissioners, it was stated that the adjoining empty houses would be pulled down at once, and a verdict of accidental death was returned.

A handsome tea-service, and several articles of plate, have been presented to Mr. W. W. Lake, city surveyor of Norwich, by members of the corporation and other friends, in connection with his approaching marriage.

The organ in St. Philip's Church, Kennington, S.E., was reopened on Sunday week, after enlargement and improvement, carried out by Mr. R. Forster, of Kennington.

The directors and shareholders of the Norwich waterworks company made an official inspection on Wednesday week of the new pumping-works in the suburb of Heigham, which are now nearly complete. The new engines will pump 2,000 gallons per minute, and have been constructed by Messrs. T. Clayton and Son, of Preston, from the designs of Messrs. T. and C. Hawkesley, of Great George-street, Westminster. The works and the erection of new offices in Surrey-street, Norwich, have been carried out under the direction of the company's manager, Mr. Ayris.

The premises above the shop of Messrs. Lund, in Cornhill, E.C., are being rebuilt in Renaissance style from the designs of Mr. E. Gregg. The builders are Messrs. Hall, Beddall, and Co., of Pitfield Wharf, Lambeth.

Our Office Table.

THE death is announced of Mr. Alfred Wm. Morant, engineer to the Leeds Corporation, which took place at his residence, Virginia-road, Leeds, last Thursday week. The deceased gentleman, who was 53 years of age, was born in the south of England, and his early life was spent in London. He first officiated in the capacity of borough surveyor at Great Yarmouth, and then removed to Norwich, where his ability as a sanitary engineer, in the construction of the Norwich drainage works, was manifested. He was appointed borough engineer of Leeds in December, 1872, in the place of Mr. Fowler, who is at present borough surveyor at Newcastle-on-Tyne. Since his appointment he has carried out the Leeds sewage works at Knostrop to their present state of completeness, designed and carried out the extension of the Kirkgate market and the fish market, the improvement of York-street, the widening of Wellington Bridge, the laying out of roads in Roundhay Park; designed and constructed the large extension of the sewerage system of Leeds for the out-districts, the connection of Armley with Kirkstall by bridges and viaducts across the river Aire and the Leeds and Liverpool Canal; and introduced in Leeds the present system of the ventilation of sewers through gullies, referring to which a few days ago at Exeter, Mr. R. Rawlinson, C.B., chief engineer to the Local Government Board, stated that the Leeds sewers were the best ventilated in England. Mr. Morant, who was a Fellow of the Society of Antiquaries, a Fellow of the Geological Society, and a member of the Institute of Civil Engineers, was a gentleman of considerable literary ability and archaeological attainments. He was president of the Association of Municipal and Sanitary Engineers for 1880-81, which body it will be remembered visited Leeds recently, and on which occasion he delivered an address on sanitary science, with reference to the departments connected with the Leeds Corporation. For one year he was vice-president of the Leeds Architectural Association. He edited the latest edition of Whitaker's "Craven," and also the latest edition of Dodgson's "Guide to Leeds."

THE trustees of the National Portrait Gallery, in issuing their 24th annual report, deplore the loss of Lord Beaconsfield, who was one of their number, and whose place has been supplied by Lord Edmund Fitzmaurice, M.P. The list of 251 donations given in former reports has now amounted to 256; and the purchases, which last amounted to 358, are now 380. Since the date of the last report 38 portraits have been protected by glass. Various autographs have been given to the gallery, including those of Sterne, Johnson, Lord Eldon, Keats, and Herne Tocke. The number of visitors to the gallery in 1880 was 76,109 or 12,075 in excess of the number the year before; the total since the opening in 1859 has been 968,571. The trustees refer to the fire which broke out in the south-west corner of the building from the overheating of a flue on the 28th January last, but was fortunately checked in time. They urge that the shaft and furnace used to heat the water for warming the building should be placed apart from the building itself. The report states that the catalogue, which had been long in preparation, has now been completed, and is issued by Her Majesty's printers, price one shilling. A cheaper and abridged edition is in preparation.

A DRAFT BILL for the improvement of the Patent Laws has been prepared by a committee of the Society of Arts, and is published by the society for public consideration. The Bill takes a wide range, and proposes to make the Patent Office—reconstituted, it is hardly necessary to say—a tribunal for the trial of patent cases. The Bill also proposes to substitute an active Board of Patent Commissioners for the present nominal Commissioners. It follows the last Government Bill of 1879 in giving great powers to the patentee to amend his specification. It increases the term of a patent from fourteen years to seventeen, while decreasing the fees to about one-half the present scale. It gives the Commissioners of Patents power, not to refuse a patent to any applicant, but to see that the applicant's description is accurate and intelligible, so that the public may have full information of the invention when it is free for their use. The Bill is

drawn in a spirit friendly to the inventor, and careful of his interests.

MESSRS. UNDERHILL and Co. have just completed new and extensive show-rooms at their premises, 170 to 173 Upper Thames-street, which are well worth inspection. They have over one hundred chimney-pieces on view, fitted in every style and material, and suitable for every class of dwelling-house. A speciality in wood chimney-pieces and tiled registers, very substantial and very cheap, is a set sold for £6 7s. 6d., comprising a wood chimney-piece in walnut, oak, mahogany or ebony, with black marble slips complete, a register-grate with tiled sides, a hearth of glazed tiles to match, and a black crest or fender. A self-setting range for cottages and model dwellings, named the "Ivanhoe," should also be examined. A new grate on an improved principle is to be on view shortly, and we shall probably have something to say about it.

At a meeting on Wednesday of the subscribers to the proposed Art Gallery and Industrial Museum for Birmingham, the Mayor, Alderman Chamberlain, who presided, announced that the total amount of the subscriptions already received was £6,949, exclusive of the Messrs. Tangye's donation of £10,000. On the motion of the chairman, it was resolved that the funds as collected should be handed over to the Art Gallery Purchase Committee, who would be guided in their purchases by the recommendations of the Free Library Committee, and would receive valuable assistance from the Department of Science and Art at South Kensington.

THE work of boring the Arlberg tunnel is proceeding very satisfactorily, and at a speed which affords a striking illustration of the improvements which have lately been effected in the art of mountain tunneling. The Mont Cenis tunnel was bored at the rate of 1,112 metres a year, the St. Gothard at the rate of 1,670 metres, and the Arlberg is expected to be pierced at the rate of 2,160 metres. The Arlberg engineers are also profiting by the experiences of their predecessors in the matter of cost, for while the outlay on the Mont Cenis tunnel was £400 per running metre, and has been hitherto on the St. Gothard £250, the expense of making the Arlberg will not exceed £150 the metre. In this regard, however, the tunnel last named benefits by its shortness, since the longer the tunnel, other things being equal, the greater is its relative cost. An interesting experiment is being made in the Arlberg tunnel with a new sort of perforator. This system is the one in use on the eastern or Austrian side of the Arlberg. The chisels cover a space of seven square metres, and make 20 to 25 holes at one time, each from 1½ to 2 metres deep. These are then filled with dynamite, and the mine exploded. Every blast lengthens the drift by about 1½ metre. The perforators move forward on wheels, and the air, compressed to a pressure of five atmospheres, is supplied through flexible tubes. On the west side drills are employed, of a diameter of 70 millimetres, to which, by means of a water pressure of from 60 to 100 atmospheres, a rotary movement is communicated. Six or eight of these drills are as effective as 20 to 25 of the atmospheric perforator, and the holes they make are so much wider that equal results are produced with lighter charges of dynamite.

WE recently visited Mr. H. Harvey's studio and found there several works of art as creditable as any we have seen for the last ten or fifteen years. Mr. Harvey has been for years a distinguished student at South Kensington. In 1878 he exhibited a bust of Dr. Zerk at the Royal Academy. He was next commissioned to make, in terra-cotta, the bust of the Right Hon. Lord Aberdare, President of the Royal Historical Society. He also executed in terra-cotta a likeness of Mr. Marshall, R.A., and in marble another of Lieutenant Shergold Smith, R.N., which is placed in the Church Missionary Hall in the City. Mr. Harvey's model of an "alms-dish," in plaster of Paris, sent in for competition to the Goldsmiths' Company, obtained the first prize of £50. About twenty raised figures form the centre-piece, representing the High Priest of the Jews in the act of laying the sins of the people on the scape-goat. The border is ornamented with pomegranates and three shields placed in triangular order, sym-

bolic of the Trinity—bear the effigies of "Fides," "Spes," and "Caritas." A small fancy composition, "A boy playing with top," now in the possession of Mr. C. J. Freake, is spirited and full of charm. The same may be said of a "Youthful Warrior," purchased by Lady Francis Bushby. A "Crusader," who, by the side of his fallen wounded horse, raises his battle-axe, apparently shouting, "No surrender!" is a composition worthy of being executed in bronze, and to be placed on one of our empty pedestals on the Embankment. The sculptor's latest work is a terra-cotta bust of General Sir Frederick Roberts.

In a report on German railways recently presented to the members of the Federal Council, by the Minister of Public Works, it is stated that on the 1st of January, 1880, the railway-lines in use amounted to 32,890k. The increase from 1870 to 1879 had been 80·5 per cent. The Government have decided to drop the work of constructing railways at present, and to give attention to the improvement of water-ways. A project for junction of the Rhine, the Weser, and the Elbe, is being studied. The waterway at present connecting the Oder with the Elbe by the Frederick William Canal, the Spree and the Havel, will, doubtless, soon give place to another more convenient. It is extremely long and costly, for it is impossible to keep it at a draught of water sufficient for vessels of more than 300 tons. The proposal is to make two direct canals, with large draught of water, one from the Elbe to the Spree; the other from the Spree to the Oder. The latter will be begun first, and should be complete in about four years.

THE preparation of a design for the diploma to be awarded by the Parkes Museum in connection with the Hygienic Exhibition, now open at South Kensington, was intrusted to Mr. Cave Thomas. The composition exhibits in the centre a female figure, representing Sanitary Science, standing at the prow of a boat in the act of casting her "life-buoy" (hygiene) into the "seething ocean of human ills." On Monday next Mr. Eric Erichsen and the Exhibition Committee will be present at the exhibition during the afternoon, to receive the members of the International Medical Congress. The exhibition will finally close on the 13th of August. The list of awards has not reached us up to the time of going to press.

CHIPS.

A colliers' hall is about to be built at Cwmtillery for the South Wales Colliery Company. Mr. E. A. Lansdowne, of High-street, Newport, Mon., is the architect.

On Tuesday week, William Imrie, late inspector of cleansing for the burgh of Perth, was sentenced to two months' imprisonment for having misappropriated corporation moneys, by entering in the wages-book the names of labourers who had no existence.

Extensive alterations and improvements are being made to the Royal Music Hall at Swansea, including the addition of a subsidiary hall in native freestone. The contract has been taken by Mr. David Morgan, of the same town.

A new manager's offices and house, entrance-gateway, and lodge are about to be erected at the Bishop's Auckland gas company's new works at Fielding's Bridge, near that town. Messrs. W. V. Thompson and Garry, of Market-place, Bishop Auckland, are the architects.

A new school at Penybanc was opened by the chairman of the School Board for Gelligaer on Monday. It cost over £700, and accommodates 80 children. Mr. John Williams, of Merthyr, was the architect, and Mr. Thomas Williams, of Bargoed, the contractor.

New Board-schools at Humberstone, near Leicester, were opened on Saturday afternoon. The buildings accommodate 407 children, and have cost about £5,000. Messrs. Bird and Sons were the architects, and Mr. Hutchinson was the builder.

A coffee-tavern was opened at Thornbury, near Bristol, by Sir Wilfrid Lawson on Saturday. The alterations to the premises, which were previously used as a school, were carried out by Mr. Burchill, and the fittings were supplied by Messrs. Paruall, of Victoria-street, Bristol.

The Plymouth Workmen's Dwellings Company are about to erect four blocks of industrial tenements on an estate at Clare-place, Sutton-place, Plymouth. Messrs. Hine and Odgers, of Lockyer-street, are the architects.

A stained-glass window has just been placed in the north side of the chancel of St. Mary's Church, Nottingham, as a memorial of the late Lord Belper. The subjects are taken from the life of St. Paul. Messrs. Clayton and Bell, of Regent-street, London, carried out the window, which will be unveiled on Sunday next.

At the Chester Diocesan Consistory Court on Thursday week, faculties were granted for the erection of a vestry on south side of St. James's, Sutton-by-Macclesfield, and the erection of a marble tablet in that church: for the filling of a two-light window in St. Mary's Church, Upton, with stained glass; and for the substitution of a new for an old font in Christ Church, Cloughton.

The Newry board of guardians have received a report from Mr. R. P. W. Birch, C.E., of London, upon the best means of draining the rising watering-place of Warrenpoint, upon Lough Carlingford, in which he recommends a plan of sewage disposal estimated to cost £3,596. The plans have not yet been formally adopted, as strong opposition is threatened by the proprietor of a neighbouring mansion.

The foundation-stone of a new Orphanage of St. Edward was laid at West Malvern on Friday. The building covers an area of 5ft. by 23ft. 6in., and will be planned as a school and class-room for 120 boys on ground-floor, with dormitories for 80 boys above; at the rear is a large playground. The materials used are Malvern stone and brick, and the estimated cost is £1,400. Mr. F. W. Hunt, of London, is the architect, and Mr. R. H. Smith, of West Malvern, the contractor.

A new Board-school for infants was opened at Dinas, in the Rhondda Valley, on Monday. Mr. Jenkin Evans, of Treorky, is the architect, and Messrs. Morgan and Jones, of Tonypandy, are the builders. The cost was £1,100.

The free library and museum in the New University Buildings at Nottingham were opened for use on Monday.

Holloway's Ointment should be well rubbed upon the pit of the stomach and region of the heart in that particular form of indigestion which gives rise to palpitation, shortness of breath, and a suffocating sensation. Every distressing symptom soon yields, digestion becomes easy, the spirits light, and good health returns. —ADVT.

TENDERS.

Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender—it adds to the value of the information.

BRIXTON, S.W.—For erection of offices for superintendent of visitors and for school correspondents, on a site in Stockwell-road, Brixton, for the London School Board:—
McCormick and Sons ... £1,965 0 0
Kirk and Randall ... 1,890 0 0
Staines and Son ... 1,782 0 0
Hobson, J. D. ... 1,759 0 0
Nightingale, B. E. ... 1,695 0 0
Marland, J. ... 1,647 0 0
Jerrard, S. J. ... 1,643 0 0
Hodge and Hill, Crown Works, South Lambeth (accepted) ... 1,640 0 0

BARNET.—For gas, bell, and hot-water works on the Manor estate:—

Macgillivray, D., Camden Town (accepted).

BARNESBURY.—For pewterer's work at the Montrose Tavern, 30, St. James-road, Barnesbury, for Mr. John Chinnery. Mr. W. F. Potter, architect:—

Edwards, J. C., Camden Town	£72 15 0
Watts and Co., Euston-road	68 17 0
Richards, J., Clerkenwell	61 0 0
Burley, W., Holloway	59 10 0
Lemon, S., Chiswell-street (accepted)	53 0 0

For gas-fittings at the same:—

Dodson, J., Fetter-lane	52 10 0
Cox, H., Islington	48 18 6
Butler, G. W., Barnesbury	47 7 0
Lemou, S., Chiswell-street	46 0 0
Humphreys, J. G., Holloway-road	43 10 0
Price, M., Old-street, St. Luke's	40 18 0
Crouch, J., Barnesbury (accepted)	40 0 0

BETHNAL GREEN.—For the erection of a mortuary and contagious-diseases wards, at St. Matthew's, Bethnal Green, for the Board of Guardians. Messrs. T. and W. Stone, architects:—

Edwards	£1,023 0 0
Beale	1,015 0 0
Steele Bros.	989 0 0
Thomason	990 0 0
Wire	929 0 0
Boyce	927 0 0
Young	910 0 0
Shurman	891 0 0
Jackson and Todd	880 0 0
Cox	878 0 0
Hunt	845 0 0
Johnson	822 0 0
Judd	795 0 0
Garrett	777 0 0
Wood (accepted)	777 0 0

BETHNAL HILL.—For new Congregational church, Burgess Hill, Sussex. Mr. E. J. Hamilton, Brighton, architect. Quantities supplied:—	
Estimate.	Total.
£2,529 0 0	£2,499 0 0
230 0 0	2481 0 0
20 0 0	2448 10 0
50 0 0	2424 0 0
27 0 0	2342 0 0

40 0 0	1,895 0 0
100 0 0	1,805 0 0
1,905 0 0	(Architect's estimate, £2,000.)

CAMDEN-ROAD.—For repairs, &c., to six houses in Sandall-road. Mr. W. Hall, 25, Southampton-buildings, Chancery-lane, surveyor:—

Medley	£200 0 0
J. nes	180 0 0
Jerrard	175 0 0

CAMDEN TOWN.—For repairs and alterations to No. 127, High-street, for Mr. Sizer. Mr. W. Hall, 25, Southampton-buildings, Chancery-lane, surveyor:—

Krene	£147 0 0
Gould and Frand	147 0 0
Rabson	138 0 0

CHESHIRE.—For deepening a well at Great Sutton, for the Wirral board of guardians:—
Thomas, W., New Ferry (accepted) £30 0 0

[Three other tenders, of £37, £97 9s., and £118 10s. respectively, received.]

EAST GRINSTEAD.—For the erection of new girls' school, for the East Grinstead School Board. Mr. S. W. Haughton, East Grinstead, architect. Quantities by the architect:—

Jones and Co., Gloucester	£1,443 0 0
Martin, F., East Grinstead	1,340 0 0
Peat, R., Redhill	1,317 0 0
Claridge, C., Bagnbury	1,220 0 0
Waters, J., Forest-row	1,195 0 0
Penn, G. and F., Fembury	1,185 0 0
Morris, J., East Grinstead	1,100 0 0
Martin, H.	1,094 0 0
Charwood Bros.	1,065 0 0
Beard	1,053 0 0
Godly, J.	998 0 0

FAREHAM.—For new dining-room and other additions to the residence, at Farnham, of Mr. E. Goble, County Coroner, Hants. Mr. A. Ford, A.M.I.C.E., Portsmouth, architect:—

Jutte	£530 0 0
Gambin	474 6 7

FERNE PARK.—For ten houses, Ferne Park. Messrs. Waymouth, architects:—

Churchward	£7,900 0 0
Shannon and Grist	7,690 0 0
Shurman	7,380 0 0
Morton	6,900 0 0

DERBY.—For the erection of a new 40-gr. brewery at Derby, for Messrs. Stretton Bros. Messrs. Scamell and Colyer, 18, Great George-street, Westminster, S.W. architects and engineers. Quantities by Messrs. R. L. Curtis and Sons:—

Contract No. 1:—Building.	
Kirk and Randall, Woolwich	£6,928 0 0
Grimwood and Sons, London	6,378 0 0
Woods, J., Derby	6,246 0 0
Dakin, J., Lichfield	6,222 0 0
Brown, J., London	6,200 0 0
Lovatt, F., Wolverhampton	5,845 0 0

Contract No. 2:—Girders and Columns.	
Morewood and Co., Birmingham	1,730 0 0

Plumber's, painter's, and glazier's work:—	
Burrows, J.	298 0 0
Smith and ironfounder's work:—	
Rankin, R. and J., and Co.	80 0 0

£2,366 10 0

LIVERPOOL.—For the erection of a villa residence in Sefton Park, for Mr. E. L. Wigan. Mr. W. W. Thomas, Stephenson Chambers, 25, Lord-street, Liverpool, architect:—
Morton, G. ... £5,500 0 0

LIVERPOOL.—For additions to Shaftesbury Hotel, Mount Pleasant, for Mr. J. W. Lloyd. Mr. W. W. Thomas, 25, Lord-street, Liverpool, and Aberystwith, architect and surveyor:—
Brown and Backhouse ... £1,151 0 0

THE BUILDING NEWS.

LONDON, FRIDAY, AUGUST 12, 1881.

PROVINCIAL ART MUSEUMS.

WE are disposed to agree with Mr. Storey Maskelyne that it is to Mr. Slagg's speech in the discussion in the House of Commons on Monday last, rather than to that of Mr. Collings, that we are to look for the true index to a solution of the question started. We do not like the apparent attempt to institute unpleasant comparisons between the facilities enjoyed by the metropolis and the great provincial towns, and we cannot see where else than in the capital the principal art examples gathered together at the British Museum and South Kensington are to be placed with half as much chance of being seen by the bulk of the nation. Nobody, we suppose, proposes to send the Elgin Marbles travelling about the kingdom like an itinerant waxworks exhibition, and few provincials, whether they are art-workmen or mere sightseers, will decline to admit that it is better that the highest and best specimens of art and art-workmanship should be safely housed in some accessible centre, than that they should be distributed in fifty provincial museums, each requiring to be visited in their turn if the whole of the objects are to be seen. If it is simply proposed to aid provincial towns to make a fresh start in founding local museums filled with objects selected by local authorities, some people who are rude enough to believe that a considerable amount of rubbish is to be found at South Kensington itself, may ask for some reasonable guarantee against a useless waste of State money by uninformed persons. It is not so long since a correspondent expressed, in these columns, his astonishment, mingled with pardonable pride, at finding a chair of his own make gravely labelled as the work of a manufacturer dead many decades. What has happened at South Kensington may happen more frequently elsewhere, but less frequently, we should imagine, where sufficient love for art or a perception of the need for developing local industries has existed to induce local self-help. There are some advocates of local museums who point with confidence to the existence of similar institutions in Flanders and Germany and France; but these people forget that in Germany, where such museums exist, the towns were capitals not so very long since, and that the local museums in France, though doubtless now subsidised by the central Government, were not founded by it—at least, they were not founded by it in any such way as would command approval in this country. If Mr. Mundella could lay his hands to-morrow on Hampton Court Palace, Chatsworth, Hatfield, and a dozen more royal and noble seats, where for years the owners have gathered together priceless accumulations of art-treasures, and roughly divide them between Birmingham, Manchester, Leeds, Newcastle, and a score of smaller provincial towns, he would be able to found local museums as cheaply and as readily as the National Convention did at the instance of Roland in 1792. If in a year or two Mr. Gladstone quarrelled with France, invaded her successfully, and directed the British generals to follow the example of the First Napoleon and send home as many pictures and other art-objects as they could tear down from the churches and public buildings, we might soon accumulate a collection as the French did in 1800, wherewith still further to endow our local museums. We are, however, reasonably

sure no such cheap means of making a beginning is before us. Anything wanted must be bought and paid for, and whether bought by the central authorities, or with money entrusted to local men, the cost will be considerable, and it is questionable, after all, whether the people generally will consent, through their representatives, to incur it for the benefit of a few favoured towns. The people of Ipswich or Exeter may care little about paying their insignificant quota towards the enrichment of the Metropolitan museums, which most of them are almost certain to see at least once in their lifetime; but they may reasonably object to be more heavily taxed for the sake of benefiting other towns which they are scarcely likely to visit, and with which they have no sort of connection. There are other champions of provincial art who admit that it is impossible to reproduce pictures and some other art objects, but that there are works in stone and metal, casts of which may be taken at nominal cost and scattered through the country. We have not yet noted any such marked influence on native art from the study of these reproductions as to make us very enthusiastic about the benefits likely to be derived from their indefinite multiplication. Such facilities may develop and improve art-workmanship, but for art itself we are not sure that they do very much—they certainly fill up vacant space and sometimes mystify the ordinary visitor after a rather ludicrous manner.

If State subventions to the provinces are to be the rule at any future time, we should like an instance, now in progress at Limoges, to form the example for all parties concerned. Limoges, one of the great French pottery and porcelain centres, acquired a museum of her own in 1869 by the liberality of one of her citizens, which has since been considerably added to and improved. The State is now about to take over this museum and the school of design attached to it, to extend both of them, and to make them national institutions. The town gives all the present buildings, the land on which they stand, and collections, and further engages to pay down a lump sum of £9,600, and a yearly subvention of £1,400. The State engages to spend £22,400, which will make up the sum required to start both school and museum on the most liberal scale. Let our own provincial towns form their own museums and galleries—as indeed several of them have already done—and then when the subject can be fairly and thoroughly discussed, they may perhaps with some prospect of success call on the State for further aid. The matter had really no chance of adequate discussion on Monday night, for, as the *Times* truly enough said on Tuesday, "the subject is one that has an interest of its own, and that deserves to be separately discussed in the House and separately considered outside. It is one of the misfortunes of this extraordinary Session that motions which are not strangled in the birth are huddled together to die of over-crowding. In ordinary times the question of reorganising the national museums for the benefit of the great towns would have had an evening to itself. This year it comes at the tail of a Ministerial statement with which it has only the remotest connection."

COMPETITIVE DESIGNS FOR CHRISTMAS AND NEW YEAR CARDS.

OF the many purposes to which the talent of the artist is now applied, the most recent probably is that of the decoration of Christmas and New Year cards, a branch of art manufacture which has grown to considerable proportions. Messrs. Hildesheimer and Faulkner, publishers, of Jewin-street,

are enterprising enough to have recently offered £3,500 in prizes for the best designs submitted in competition for cards, and these are now on view at the Suffolk-street Galleries, Pall Mall. Thirty prizes, amounting in all to £2,000, have probably by this time been awarded by the judges, Messrs. J. E. Millais, R.A., Marcus Stone, A.R.A., and G. A. Storey, A.R.A., to whom the designs have been referred. In addition to these prizes, Messrs. Hildesheimer and Faulkner have guaranteed to select seventy sets of designs, for which prizes of £25 and £20 will be given, making altogether the sum above mentioned. The sums offered have probably induced even artists of repute to enter the list. The prize-list will be published on Monday next. All the designs have been sent in under motto, and the large galleries in Suffolk-street, Pall Mall, are crowded with them.

It is not surprising to find these designs vary very much in their composition, and, in fact, reflect the very different tastes of the public. They may roughly be divided into the pictorial, sentimental, emblematic, and decorative. In the former of these classes we find the natural landscape, or the quaintly-drawn figure subjects and pictorial nursery rhymes suitable for the young; in the sentimental class we may put those compositions in which the valentine element is largely introduced; in the emblematic, the bouquet and the language of flowers are common, while the decorative class includes designs in which the artist has attempted to weave in a conventional manner the appropriate emblems into a texture of his own fancy. It would be an endless task to give an idea of even the principal designs in these classes, and we may therefore dismiss at once from consideration those designs for souvenir cards in which natural landscapes, types of female beauty, and bouquets of flowers have been introduced. These subjects are, as may be expected, overwhelmingly present in the collection, and we hope the judges, who are, by the way, more painters than decorative artists, will give a preference to those designs in which the emblematic and decorative treatment of a complimentary card has been kept in view. It is needless to say many of the landscapes, figure-subjects, and flowers are drawn with consummate care and finish, and several of them are worthy of being placed in an exhibition of cabinet pictures. Some of the portraits of feminine beauty show the work of the artist also, while the flower-subjects are finished with a delicacy of handling and execution highly creditable to their authors. We consider, however, such highly-finished pictures as "Aspiro," "Farmer," Nos. 40, 44, and others, out of place on a Christmas or complimentary card, and such themes appear to us less suitable the greater their literal fidelity to nature. "Veni vidi" is the motto of a pretty device, in which ferns and butterflies are arranged on light pea-green cards, though a thorough natural rendering is apparent. The designs, showing farmyards in winter-time, and landscapes with figures are well drawn, but singularly unmeaning, and floral devices with butterflies, cherubs, cupids, and pictures of Cinderella, can only be looked at as copies of the picture-cards and valentines we have been wont to see in ladies' albums. No. 30 is a more honest attempt to amuse the young, the droll outlined figures dilly tiuted, with the lines, "At Christmas time ye waites doe playe with many a merrie roundelaye," are artistically drawn, and put us in mind of the excellent series of nursery-rhyme picture-books lately published. "Esperance," another quaintly-drawn series of figure-subjects, with flat washes of tint, represents Christmas in the olden time. No. 42 is a folding card with three carefully-drawn figures of Faith, Hope and Charity, the latter being the centre one,

the outer cover is adorned by a vesica-shaped panel having a figure in it. The lines are from Spenser's "Faerie Queen." "Ye days of old" represent Christmas scenes, with a clever black and white border. Amongst a variety of several commonplace subjects we meet with a rather chimerical design—a kind of phantasmagorical idea in colour, in which figures and peacocks' feathers are combined. Flowers in vases, with motto, "Hodie mihi, Cras tibi," is pretty; and near it (No. 65) a clever conventionalised idea, Japanese in design, with foliage and birds upon a dark blue reticulated ground, may be seen. There are four designs for Christmas, New Year, and two for birthday cards. "Nunc aut Nunquam" represents four girls in differently-coloured gowns emblematic of the seasons. The flowers (No. 83) are cleverly painted in oil on dark grey grounds, and the nursery rhymes in "Light" are quaintly conceived in an artistic spirit, and the figures representing Jack and Jill, &c., are well drawn. The figures of the seasons in "Fac et spera" show a conventional treatment pleasingly coloured and somewhat Burne-Jonesian in style; and a great many of the competing artists show allegorical representations of the seasons. In 105 the artist has worked out a pretty idea in a Japanese fashion, and the colours green, gold, and brown are tasteful and emblematic. The motif is purely decorative, and a conventional rendering predominates. Children's cards are a leading feature in the exhibition, and many of these are very pleasing souvenirs, as in "Forward," where the seasons are represented by figures of romping juveniles; "Light Hearts," "Spero," a very poetical and decorative treatment, "Res quam," in which fairy-scenes are introduced. "Fide et Amore" are studies of female heads, rather too much of portraits. "Dresden China" is rather a comical conceit; we may also notice "Isca," emblematic figures, Autumn and Winter (142), "Aspire and Rise," and a decorative design with borders and mottoes (153). One of the cleverest decorative designs, "Godspeed" (171) shows a conventionalised arrangement of ferns and leaves on coloured grounds representing the seasons. The designs are in a Japanese spirit, and the colours are well blended and harmonised. No. 172, roses in china bowls, is too naturalistic. We pick out of many commonplace conceptions "Valentine Writing" (181); "Sun, Wind, and Rain," prettily coloured; a decorative design with flowers upon ornamental background (199). A quaint sepia group of figures, with an Ode to Winter, a Shakespearean fancy is "Cor ne edito"; winter scenes (218) highly finished; framed landscapes and marine subjects introduced on a background of trees (212), and a variety of floral devices, wild flowers, and grasses, show fertility of fancy. "Never Despair" (257), with flowers in borders, is a little out of the beaten track; and we might mention "Faith," in which wild flowers have been cleverly drawn. Among the naturalistic flower devices is "Labore sine favore" (287); "Work and Live" (303), with birds and flowers, has some originality; and in the corner of room we find four clever water-colour sketches of towers at Rouen, Ghent, Bruges, and Calais, the appropriateness of which for cards seems rather questionable. Some of the artists have introduced rather out-of-the-way and puerile fancies. What, for instance, can Shetland ponies, cats, and dogs, suggest as suitable decoration for Christmas cards? but we pass on to notice some prettily-grouped roses on grey paper, "Always Ready" (331), and a long decorative design for folding cards (332), more suited for a panel. The clouds, with wide borders, having flowers, is rather a good idea, and artistically carried out; the seasons are suggestive,

and the execution is highly finished. On the end wall we find also a few pleasing designs treated decoratively. "Deo juvante" (342), "Try" (344), and "Creta" (347), are all prettily conceived and drawn. No. 409 is another clever Japanese treatment, in which the setting sun is introduced amid folial devices. It is decorative, but stiff in the drawing of shrubs. Flowers in vases have been taken by a great many designers, but in "Juste Judicio" (440), they have been prettily grouped, and relieved by backgrounds of various colours, emblematic of the seasons. For a folding card, No. 454, flowers in front, with shades of colouring in the backs, is well adapted; the arrangement is decorative in feeling, and the flowers well drawn and coloured. Nos. 461 and 467 are also flower devices, and No. 474 is rather fresh, but unmeaning in its Japanese jumble; it looks like a puzzle. The flowers and grasses in 483, upon grey-tinted cards, are drawn with masterly skill.

A panel arrangement in which the hexagon is introduced, but rather formally, is shown in No. 485; fans and flowers have been combined in No. 499 with some suggestion, but many of the arrangements affect the aesthetic rather purposelessly. A rather remarkable idea is covering the memento card with pictures of church porches. "Audito libenter" (250) has done this, and has taken real Norman and Gothic porches to illustrate or symbolise the meaning.

The other rooms are full of designs, but of less interest, to which we have no space to refer; several of these are in black and white, and represent landscapes, figures, animals, rustic scenes, Japanese and decorative subjects, in sepia and India ink. One of the best is "Trust" (669) a clever mingling of colour, figures, and fans on gold and blue grounds. No. 785, designs in gold and silver, is also a fanciful idea. We also note 810, a pleasing floral design, 903, 935, 936, and on the screen, Nos. 1, 102, No. 1, 126, a cleverly-disposed Japanese design well coloured. Those who can spare the time to visit this exhibition will find much to interest and amuse. Every conceivable image which can be suggested by nature, art, and the most capricious imagination, has been laid under contribution, and applied with more or less artistic sense. Allegories, fables, nursery-rhymes, comic representations, riddles, grotesqueries, sports, and charades, have supplied suggestions in such an abundance, that it is difficult to imagine any fancy that has not been turned to account. Leaves, flowers, and fruit, birds, and classical or decorative figures and emblems, supply material for the most exquisite artistic memento cards; and the exhibition, which has been so well arranged under the management of Mr. Edward Freeman, affords the visitor means of comparing the powers and capabilities of the artists. The judges will have no difficulty in selecting those in which ingenuity and decorative fancy are most displayed, having reference more particularly to the requirements of this form of souvenir, and keeping in view the principle of emblematic, tasteful, and appropriate decoration, rather than picture-cards.

COMPETITION DESIGNS FOR THE PROPOSED EXCHANGE STATION, LIVERPOOL.

IN another part of our issue we publish the award in the above competition. The first premiated design submitted under the motto "Mai," by Mr. John West, of 4, South Parade, Manchester, utilises the present booking-offices and station-buildings, and preserves as much as possible the existing levels and approaches. In his report the author says, "At first sight it seems natural

that both the approach to and the debouch from the station should be together in actual practice; however, it is not the case, but there are certain advantages in keeping them separate, especially where there is a large emigrant traffic." The present western approach is not altered materially; but the exit from the debouch on the arrival platforms is moved further up Tithebarn-street to a central position, opposite Moorfield-street. Blocks of shops and offices are contemplated along part of the present debouch, and the new one is planned to leave room for a similar block on the eastern side. The plan provides for a new 10-ft. covered-in staircase in connection with the booking-offices, and another 6ft. stair is placed half-way up the incline to communicate with Pall Mall. The new debouch has a gradient of 1 in 16.

Referring to the booking-offices and station-buildings, the author proposes to clear away the east wing block, retaining the front and west blocks, and adapting them to the new circumstances. A new block of buildings, in rear of and parallel to the existing front block, is shown for the additional requirements. The author directs attention to a special feature of the design—namely, the unbroken transverse platform, 85 yards by 15 yards, communicating with the principal longitudinal platform, and having round it and abutting thereon, the whole of the offices, waiting-rooms, and conveniences. By this plan the several departments are rendered easy of access as well as separate and distinct. Provision is made for emigrants in connection with the new debouch. Other minor alterations are suggested. The floor of new buildings and transverse platform are to be kept at the same level as the present floor of booking-office, and inclines will be made to 3ft. above rail-level, or that of the new longitudinal platforms.

The roof over the transverse platform is intended to be entirely of glass, on the ridge and furrow principle, supported by lattice girders, and the main station-roof is in three spans, supported on cast-iron pillars 35ft. apart.

The design which has obtained the second premium, "Omega," by Mr. H. J. Percival, Newchurch, near Manchester, also preserves the existing buildings, and therefore minimises the cost. In this plan there is an entrance-tower to subway to booking-office, and a semi-subway and steps to same; an entrance to excursion-platform and another for carts. Shops and basements are proposed along the frontage to Tithebarn-street. The present building is altered for waiting-rooms with dining-rooms above. The roof is in two spans, of about 164ft. each, supported on columns 50ft. apart, and lattice or Warren girders 14ft. deep transversely to the run of metals—on these are the ordinary iron roofs hipped at both sides.

The third premiated design, "O. C. S.," by Mr. Thos. Mitchell, F.R.I.B.A., which we shall illustrate next week, was, we understand, placed first on the list by the directors and their traffic-manager and engineers in the first instance. The main objects proposed by this plan are (1) convenience of traffic, (2) simplicity of arrangement, (3) utilisation of sub-structure. The author raises the gradient of existing road adjoining Toxteth-street to 1 in 24, and provides a corresponding road on the Pall Mall side. The heavy parcels, which at present cost a large sum for haulage, are taken charge of at the lower or street parcel-office, and lifted by a hoist to the platform-level. The new buildings are placed partly on the site of the old ones, and are 66ft. back from Tithebarn-street, and the author has symmetrically disposed his elevation to this street. In the centre is the booking-hall, and adjoining are the left-luggage office, with a hoist, and the waiting-rooms, and abutting on these are the

refreshment-rooms. Half of the Tithebarn frontage has been utilised for a restaurant, from which it is expected a rental of £1,000 may be obtained; the other portion is appropriated to shops and stores. The sub-structure is extended under the permanent way by arches like the present. The style adopted is Gothic, and the estimated cost is £227,000. The quantities were taken by Mr. J. H. Andrews, St. Mary's Gate, Manchester.

"Rectus," the descriptive report of which we have received, is a very able design. The general arrangement at the rail-level follows the plan supplied by the company; the main block, 380ft. in length, fronts Tithebarn-street, but is kept back from it by a raised terrace, beneath which 12 shops are obtained in the arches between the cab approaches. The other waiting-rooms and offices are arranged in two wings attached to the principal block, one being carried over the approach-road to the station, 212ft. in length, and the other facing Pall Mall, 185ft. in length. Ample accommodation has been provided, and the cab approach is arranged on an easy gradient. The main roof is in two crescent-shaped spans. The elevation shows a central clock tower, surmounted by a small peristyle; and the booking-office front is adorned with an order of Ionic columns, standing upon an arched entrance. The extreme wings are emphasised by columns of the same order, surmounted by pediments. The details of these portions are refined, and carried out in a Greco-Italian style, dignified in the main lines, and avoiding anything commonplace or costly. The competition designs are on view in the Skating Rink, Devonshire-street, Higher Broughton, Manchester.

THE FURNITURE TRADES EXHIBITION.—II.

IN our last issue we directed attention to the Furniture Trades Exhibition, opened last Thursday week at the Agricultural Hall, and we now have to review more in detail the various manufactures and goods, useful and decorative, which have been brought together. As an experimental exhibition, it must be confessed, the promoters have to be congratulated, for although some manufacturers are conspicuous by their absence, a few of the bays and stands contain furniture and other articles which would do credit to any exhibition. So thorough a revolution has been wrought in the taste for furniture and decoration during the last twenty years, that it is not surprising to find cabinet-makers and upholsterers anxious to compete with one another in the production of what is called "art furniture." The four rows of avenues are filled with every class of manufacture, from that of the furniture dealer who caters for a general public to the class of the special maker, whose designs are prepared by well-known artists.

Messrs. Ashton and Green, of Bury-street and St. Mary Axe, occupy a prominent place in the main avenue near the entrance. Their suites of chimney-pieces in Brocatella, black, Sienna and statuary marbles, are intended to show every modern style and degree of finish. Among the collection we notice a carved black chimney-piece, with ornamental shafts of Brocatella supporting a shaped shelf. The carved foliage in the mantel and caps are of black marble, left dull, as a contrast to the polished parts: another was richly decorated with Sienna panels suitable for a drawing-room, and one or two had arched mantels and black members. These are fitted with dog-grates, or registers, in Renaissance and the Adams' style, and we notice in one instance a black marble hearth inlaid, which has a very rich effect. The statuary chimney-piece with Ionic columns is a very elaborate design, and richly carved. The registers are well

finished, and are fitted with painted tiles; the baluster-bar grates are novel, and the assortment gives a good choice from an inexpensive grate, costing about £2, to the highly-decorated brass-finished grate of £30. Close and open ranges, and especially the "Birmingham range," which can be made into a close or open fire, and is constructed so as to carry away the effluvia from frying, call for particular commendation.

Mr. James Loder, Cheltenham, is the exhibitor of some excellent sideboards, in which design and workmanship have been considered. An American walnut sideboard, with nickel-plated hinge, Jacobean, has some spirited carving to the front drawers; another in Renaissance with oxidised handles, from a design by Mr. Jouquet, has a broken pediment, with carved panels in cupboard-doors and mirrors at the back. A fumigated-oak Elizabethan sideboard, and a very rich genuine Dutch marqueterie table-top, inlaid with woods, mother-o'-pearl, and ivory, and in capital preservation, are among the exhibits. Near this, the Austrian Bent-Wood Furniture Company have a large stall stocked with chairs, of various kinds, settees, lounges, sofas, toilet-stands, jardinières, tables, and rocking-chairs, manufactured of their bent-wood. Every sort of easy and portable chair is made by this firm, and being light, the furniture is well adapted for bedroom use, boudoirs, &c.

Messrs. Jackson and Graham, Oxford-street, whose collection we glanced at last week, occupy a large central stand in the main avenue. Among the exhibits of this firm, chiefly of furniture produced by machinery at small cost, we notice a simply-treated buffet, from a design by Mr. R. W. Edis, F.S.A. The framing is exceedingly simple, the upper part having glazed lockers and shelves for china. Last week we mentioned a very effective style of wall-paneling in Late 18th-century, or after Sheraton, of painted deal, showing chimney-piece and door, the main relief consisting of panels and fluted enrichments with mouldings, the colour a greyish green. We now notice a set of bedroom furniture, painted, and of simple design. The wardrobe has mirrors and a bookshelf, the toilet-table has side lockers and drawers, supporting a toilet-glass of elongated-octagon shape, and below the table are drawers for toilet requisites. Another suite of bedroom furniture of pine, stained green, inexpensive in design, is exhibited, fitted with some very effectively-designed ware of Japanese taste. We notice also a cream-painted deal chimney-piece, with dove-marble architraves of an inexpensive kind; a drawing-room cabinet and bookcase combined; and a sideboard of eboussé wood, from a design by Mr. Edis.

Mr. M. F. C. Turpin, of Bayswater, whose parquetry we have already referred to, exhibits several well-made specimens of wood-work. We notice a carved oak chimney-piece with stove in an Italian Renaissance style, oak cabinets carved, and various specimens of parquet flooring, lin. and 5-16th in. thick, dados, carved chairs, &c. A very rich floor, the pattern being Italian in design, with foliated scrollwork, in walnut on an oak ground, may be seen; the pattern is fret-cut, and the border of walnut and oak. Other designs in walnut, oak, sycamore and mahogany, of plain geometrical patterns with appropriate borders, are exhibited. The inch fillings vary from 1s. to 4s. per square foot, and the borders are about the same. Turpin's thin parquet, specimens of which may be seen, is of course a cheaper substitute, which can be applied to any floor. It is 5-16th in. thick, the backing being in three deal laminations, laid crosswise of the grain, which renders it as strong as the inch solid, and less liable to fracture than the canvas backing. Designs for chimney-pieces and

chair-seats are among the articles to be found in this stand. Billiard-tables of various styles and sizes are exhibited by Mr. G. Edwards; we notice especially a 6ft. by 3ft. billiard and dining-table combined, which can be converted easily.

Mr. W. H. Davies, of Liverpool, exhibits an Upright Grand Pianoforte with reverberating soundboard and guitar pedal, well worth the attention of all pianists and purchasers of high-class instruments of this class. For wall decoration, one of the most interesting stands is that of Messrs. Frederick Walton and Company, Berners-street, who show their admirable "Lincrusta-Walton" in several designs and colours. A delicate salmon-pink tinted sample, relieved by an impressed pattern in the Adams' or 18th century style, gilded, and the apple-green specimen with dado of a chocolate colour, richly embossed, afford a good idea of the rich carved-like relief, which this washable and impermeable wall material is capable of receiving. Other designs are to be seen here, but we direct attention chiefly to the pleasing tints of the green and chocolate, which are the natural colours of the material, and which may be made to harmonise with any furniture. As we have said before, it can be obtained to suit any style of architecture.

In conjunction with Messrs. Walton, Messrs. Conrath and Son, of Audley-street, exhibit a very artistically-designed brass hat and umbrella stand, which is worth inspection. The patent hat-stand has no hooks for the hats, but horizontal bars of brass, a few inches apart, which catch the brim of the hat in the easiest possible manner. The hat by this means does not stick out, but assumes its normal vertical position. There is an umbrella-stand underneath, and brackets at the sides with hooks for coats.

Messrs. Steel and Garland, Holborn Viaduct, have a large display of chimney-pieces and grates, with hand-painted tiles, brass dog-grates, fenders, fire-irons. We may call attention to the tapestry-tiles for the cheeks of grates, and the mosaic imitation tile-hearth. The "Burmantofts tile covings" and the hearths in one piece, in which the tiles are embedded on a flat layer of concrete, are effective and not liable to fracture, and ashes do not get in the joints. Some of the dog-grates are made with open bars at the side, to facilitate the draught. We notice also a coal-cabinet and what-not combined; a nursery-grate, relieved with tiles representing the days of week; a hob-stove, with inlaid brass, brass fire-irons, &c. Mr. Hy. Bassant, Well-street, has a very large assortment on view of parquetry and dados in a variety of plain geometrical patterns, suitable for halls, rooms, dados, &c.; and in art-metal manufacture we draw attention to the collection of brass-work exhibited by Messrs. Jones and Willis, of Great Russell-street, &c., who have some highly-wrought lecterns and gasaliers. Their patent "Hesperus lamp" we have mentioned on previous occasions, and there is no doubt its illuminating power makes it one of the most economical lamps in the market. Some well-designed walnut cabinets and sideboards in Chippendale and other styles, are to be seen in Mr. J. A. Deintje's stand. In Bay 20 Messrs. Clark, Bunnett, and Co., Queen-street, &c., show their well-known patent revolving shutters in steel, iron, or wood; some excellent metallic Venetian blinds, a dinner-lift, and a safety-lift for invalids, a smokeless grate (Ingram's patent Kaio-Kapnos) which burns anthracite or any fuel. Spiral staircases, and other castings, stable-fittings, &c., are among the objects to which professional attention may be drawn.

As an architectural and decorative material, concrete is too important a material to pass over, and we find Mr. W. H. Lascelles, of Bunhill-row, the only repre-

material of this manufacture. Mr. Laidlaw's stove contains only three or four calibrations to which we direct special attention, indicating the degree of workmanship and high finish to which he has attained. The red concrete chimney-pipe designed by Mr. Norman Shaw, R.A., in a Queen Anne style, is an excellent specimen; the material is enriched by a bas-relief of a vine and festoons equal to carved work. Another of green colour has a bas-relief of a plant of Dickens in the centre, and a white concrete chimney-pipe, from a design by Mr. Timerson, shows some bold relief in the mould. The red hearth-tiles, with brass inlay, make a capital hearth, and we have referred to other manufactures on the occasion of a recent visit to Mr. Laidlaw's manufactory. Messrs. Ross, Fox and Co. exhibit a suite of bedroom furniture, a chest of drawers, what-not, in Canadian basswood of a wood having a pleasing grain, and another suite in Canadian white and cedar, the style being the Adams. The walnut mouldings well repay the colour. The "Otto" silent gas-engine, by Messrs. Crossley, Bros., Manchester and Poulter, is too well known to need a lengthened notice. For pumping, lifting, lifting, lathes, swing machines, &c., the "Otto" gas-engine is the most economical motor, the cost being about 1d. per h.p. per horse-power. The gas is ignited in the cylinder with air. The inexpensive oak and walnut furniture shown by Mr. H. Hermann is worth notice.

In the gallery and fittings are shown at a new stall. We notice the Yale Lock Manufacturing Company, Stamford, U.S.A., and Adams Street, Strand, which has a large display of locks, latches, and door-furniture, making their principle. The chief feature of these locks is the flat keys, made of steel or metal, which are common in the United States, and more portable than the ordinary key. The rim night-latches are of a new construction for the common kind; the door is not locked, and other locks are of a new and compact. An automatic time lock is shown also, which can be easily set to open at any hour. Mr. R. Adams, of Great Dover Street, has one or two models, showing improved methods of hanging shutters. In the safety window, the vertical sash fasteners can be made to turn on pivots without the need of a hinge. They are hung on a pivot at the right centre, and are fitted with a patent adjustable sash-fasteners, by which they are rendered air and dust-tight. The fastener can convert any ordinary sash window by taking off the inner bead and removing the parting bead. The "patent" fastening and sash-check" is an ingenious arrangement for doors. We may say a word for a patent sash-light opener, and the "patent" sash-light holder, both clever appliances. Messrs. Bell and Co. have an improved fastening kitchener worth attention. Messrs. Carter and Aynsley exhibit a large collection of brasswork and builders' ironmongery, including a patent sash appliance. Mr. Mayfield. We have already mentioned Messrs. Haldison and Clark's stall, in which we have not seen the "patent" window-blind, revolving-ironmongery, and a combination, will be found in the arrangement. It is extremely strong, and a good specimen of the art. A new blind, the "patent" window-blind, is made of iron, and is extremely strong, with a large display of choice tapestry curtains, silk, rep, and damask upholstery. The wool and silk cushioners are in excellent designs and colours. Messrs. M. J. B. Burnard and Co. are the manufacturers. Messrs. S. and H. Levi have a stall filled with terra-cotta and Devon art-pottery; the hand-etched vases are artistically executed. Last week we referred to the stand of the Papyrotile Company. We may now draw attention to the warmth and tone of this

material or leatherette, its value as an inlay and decorative material for furniture as well as walls, and its comparative cheapness as a relief. It is applied in tiles 4in. by 4in., and 4in. by 8in. They are capable of receiving any colours, though those of two shades and with gold relief are highly pleasing and artistic. The papyrotile can be cleaned, but its surface being of a glossy nature, it is far preferable to paper.

Of the many other exhibitors, we have only space to notice Messrs. Vaughan, who have a variety of suites of furniture in the latest styles; Mr. M. W. Ovens, exhibitor of side-board, of oak and walnut; Messrs. Drew and Cadman (plate glass and mirrors), C. and R. Light, Laverton and Co., Wright and Son, Chorlton and Dugdale, Brangwin and Co., and W. North and Sons; the Wilton Engineering Co. (ranges); the Eagle Range and Foundry Co.; the Art Tile Painting Co. There is little connected with the trades of furnishing and decoration which is not represented, and the number of exhibitors in each class is an augury of greater success in the future.

PORTLAND CEMENT FOR USERS.*

MR. HENRY FAIJA, C.E., is the author of a little book intended to furnish those who occasionally use cement with the practical results of experiments, without entering into elaborate researches and theories. The literature of limes and cements is already formidable enough, and the treatises which have been written on the subject, together with the more fugitive sort of papers to be found in the transactions of professional societies, are certainly beyond the practical requirements of those who daily use cement. The author's experiments and researches, instead of being minutely described, have been given in a classified form, as deductions, and several tables have been added, which will be found useful for reference. In the introductory chapter, Mr. Faija refers to the variations in manufacture, owing to differing proportions of the same raw materials, and their composition; and he speaks with some authority on the advantages that would accrue by the adoption in this country of a uniform means of testing cement, as well as of a standard of quality, such as the Governments of Germany and Austria have adopted. It is very true that such qualities as weight, specific gravity, colour, and fineness, are problematical properties, and are of no use in determining the actual qualities of cement, such as tensile strength and setting power; but when these "absolute" properties, as they are called, are known, the other criteria may be taken in determining, with some degree of accuracy, the behaviour of certain cements, just as, from certain physical signs, the physician can diagnose pretty accurately the real condition of a patient, and the probabilities of recovery.

Chapter II. discusses "weight," and shows the fallacy of making weight (by itself) a criterion of quality, when it is now known that the cements which weigh little are often superior to the heavier cements. So much for the 112lb. bushel test. To require that a bushel measure must be filled as "lightly as possible," is no test of uniformity, as everyone will have a different idea of performing that duty.

Fineness is a matter of more importance, and since the finer a cement is ground the less is its weight per struck bushel, we cannot put much faith in weight merely. The author describes a method of filling the measure to secure uniform results. The cement is placed in a hopper with a fixed spout, at an angle so that the cement will run quietly into the measure at a certain

* Portland Cement for Users. By HENRY FAIJA, C.E., Assoc. M.I.C.E., &c. London: Crosby Lockwood and Co.

height. After it is well piled up above the rim, the cement is struck to a level. The author uses a smooth iron hopper with zinc spout, fixed at an angle of 55° , the mouth of the spout being 5in. above top of measure. Weight and fineness should go together. Fine-grinding is essential to surround each particle of the aggregate, and the value of fineness in cement can hardly be overstated. Chapter IV. deals with "gauging," or the addition of water to the sample; also the form of briquette, and the amount of water used. The briquettes ought to be of a form to insure tensile strain only, and the amount of water to gauge varies much; generally from 16 per cent. to 20 per cent. is necessary. The cement must be brought into a "pasty, tenacious mass," and this condition should be attained with the minimum of water and in the shortest possible time. The directions given for filling the moulds are thoroughly practical, after which the process of "setting" is described—a word often used in a rather ambiguous sense. Some cements are quick, others slow-setting; but both kinds are advantageous—the first where strength is required speedily, and the slow-setting kind in foundations and hydraulic work. "Set" has nothing to do with hardness, but is the return to the normal temperature of a pat or briquette.

On tensile strength the author makes a few useful observations. Formerly, seven days after gauging was considered sufficient time to test a cement; but lately it has been found necessary to give a longer time, and an expiration of 28 days has been allowed in some cases. A seven-days test, however, may be applied after the longer test has been made. Regarding sectional area of briquette, 2in. is that usually adopted; but a briquette of lin. square has been found to give more uniform results from the same gauging. The variations which occur in the results are not satisfactorily explained, though by using the lin. section and having five moulds in a nest, all filled at once, the author finds the limits of deviation need not exceed 10 per cent. A uniform rate of strain is, however, essential, as the experiments recorded in the appendix show. As all cement is used with sand or ballast, it is necessary to know something of the effects it has when gauged with sand. The sand test is used in Germany, where a standard size of grain is insured; and if satisfactory evidence is wanted, the sand used for testing ought to be the same as that on the works. The sand test enables the adhesive power of a cement to be determined, but the sand should be of a uniform size and cleanliness, or the results will differ widely. Chapter VIII. discusses the chemistry of manufacture, and in the following chapter the author quotes from a paper he read before the Institute of British Architects last year to the effect that "the greater the increase in strength per cent. is between the seven and twenty-eight days tests, the stronger and harder is the cement likely to become, and that increase should be at least 25 per cent."

A light colour and light weight characterize quick-setting cements, and a heavy weight and dark colour a slow-setting cement. If properly ground the weight per bushel, according to the author, is from 108 to 116lb. "A cement that will pass through a sieve with 625 holes to the square inch, and will leave a residue of not more than 15 per cent. when sifted through a sieve having 2,500 holes to the inch, will be found to give good results, combined with a due regard to economy of production." The summary of results gives a tensile strength for a good cement briquette of 400lb. per square inch after the expiration of seven days, the briquette having been placed in water 16 or 17 hours after

gauging. Slow setting is to be desired. The colour of a true good cement is a cold grey, of a quick-setting cement, a light brown or "foxy" tint. This and the concluding chapter will give the general user all that is requisite to specify or test accurately a good cement. The author condemns, and with a good reason, the custom of tipping concrete into a foundation from a certain height. Instead of solidifying, it tends to separate the larger masses from the smaller of the aggregate, and thus the matrix is displaced. In making concrete, the dry material should be well mixed before the water is added, and this should be gradually done. We commend the reader to the remarks on the application of cement concrete, and on cement mortar, and the author shows that greater strength may be secured by using cement concrete instead of lime concrete, as a less proportion of cement would be necessary to insure equal strength. The appendices illustrate in detail the remarks, and are intended to support the conclusions, of the author. Many of the tables are from experiments made by Mr. Henry Faija, in his cement-testing room and laboratory at Westminster. Diagrams of various forms of briquette and hopper-and-shoot apparatus for filling bushel measures, testing-machines on the steel-yard and lever principle, are given; and Mr. Faija's little treatise will be found a useful compendium of results for the practical builder and architect.

THE KNOWLEDGE NECESSARY FOR THE TRUE ARTIST.

MR. J. B. MITCHELL-WITHERS delivered a very sensible address to the students of the Sheffield School of Art on the occasion of the distribution of prizes on Monday night at which he presided. He said: It is my duty to-night to address you for a few moments on the subject of art; and if I felt that I was expected to say anything novel bearing on its history or technical practice, I should hesitate to speak at all before an assembly like this, embracing, as it does, not only those who have shown their attention to it by carrying off the prizes we are about to hand them, but also some whose brows have long been adorned with the laurels of painting, sculpture, and architecture, and to whose words I should be no unwilling listener. I shall confine myself then to a rapid glance at the opportunities afforded in this Sheffield of ours to acquire the knowledge necessary to form a true artist. I do not restrict this term to any one branch of art, and I feel I shall be pardoned when I say that although it is to be hoped that some true painters may be the outcome of this school, it certainly is not its primary object to produce them. We seek to gather within its walls not only the sculptor but the stonemason; the joiner as well as the wood carver; the chaser, the engraver, the iron-worker; in fact, all on whose daily avocations art can be brought to bear. Nor do we wish to stop here. We would desire to have a firm hold on those who will have the opportunity of employing the art workman, to give them a true interest in art, which can only be truly acquired by definite and systematic study. There is little doubt that in these days art is not neglected. We have "art pottery," "art colours," "art furniture," a series of papers devoted to "art at home," and many volumes to art abroad; but to use the words of our late art director, Mr. Poynter, "It cannot be denied that in spite of all that is talked and written in sincerity and cant on the subject, we are hardly better off now than formerly. A satisfactory knowledge of art will still be found only among those who practise it, and with a few earnest lovers of it, such as have at all times assisted by their enthusiasm." Turning over the pages of Sir John Tyrwhitt's "Christian Art," I find the following:—"If we took a man out of Sheffield and educated him for years as an artist at Florence, he probably would not like Sheffield when he had to go back. But we want to teach art in Sheffield. What we are desirous of is that there should be good schools of design, and models of

beautiful work and flowers, and still-life, and even means of study from nature in all the great grimy towns on the coal-field." I am aware that one who described himself first as Mr. Tyrwhitt's master and afterwards his pupil, has stated that in the carboniferous formation on which our town is situated there is no home for the artist, no soil in which the delicate root of art can be induced to grow. But I think there is no difficulty in showing that what the author of "Christian Art" is desirous of doing can be done, and done well, if only some of the sons of Sheffield can be induced to give themselves up to steadily using such means as are at their disposal. We all know the importance to the students of science of an accurate and comprehensive knowledge of all that has been done by its pioneers and professors, as a foundation on which to build his own superstructure. This knowledge is equally necessary in art. Many an able man, whose eye had all the feeling, and whose mind the enthusiasm necessary to form an artist, has miserably failed because he knew not the elementary principles of drawing, or was too proud to learn from his predecessors. Reynolds, in his masterly discourse on painting, strongly enforces the necessity of this course. He says—"Study, therefore, the great works of the great artists for ever in the order, in the manner, and on the principles which they studied. Study nature attentively, but always with these masters in your company, and consider them as models which you are to imitate, and as rivals with whom you are to contend." There is no difficulty in carrying out this study in the building in which we are assembled, so far at least as form is concerned. Would you kneel at the highest shrine in lowly admiration of the name which Sir Joshua desired should be the last he should pronounce in his discourse—Michael Angelo—you have in the rooms around you most accurate casts of many of his greatest works. We have the Torso, which he so much admired that it is said when he became blind he used to be led close to it that he might pass his feeble hands over its form. We have the panels by Ghiberti of those gates which he praised so highly that he considered they might well be used as the gates of Paradise. Step into the library and you find that photography has produced with marvellous exactitude the roll of the master's brush as it passed with lightning rapidity over the ceiling of the Sistine Chapel, and engraving the great architectural monuments with which he adorned Italy's ancient capital. The ornamentation of the Renaissance period has not been neglected, and the Medieval sculptors who decorated the glorious cathedrals of our own and other lands are now fairly represented. On the hill which overlooks the beautiful valley of the Rivelin and the wooded slopes of Wharfedale the author of "Modern Painters" has deigned to pitch his tent and provide for those who wish to study them, examples of the art of Dürer, the early Italians, and the studies of our own great landscape painter, Turner. Should we desire to bend the ductile iron to our will and to fashion it into these forms of quaint and beautiful flower or foliage which ancient and modern artists delighted to produce, we have a rich collection in Mr. Bragg's gift to our Weston Park Museum. Why should not this art be added to our town's productions? Could not the Hallamshire man be taught to wield his hammer as well as the silk weaver of Coventry or the gunsmith of Birmingham? Do we desire to apply Sir Joshua's advice, "Study nature attentively?" Have we not the Ribblesdale and Wyming Brook, on whose banks Elmczer Elliott composed his choicest poetry? The grandeur of our moorlands, with their fine escarpments of millstone grit, the medieval remains of Conisborough, or Roche Abbey, are all subjects which are surely not mean ones for the landscape painter. The brilliant effects of light and shade with some of our manufacturing processes are not beneath the pursuit of an artist; and we can fancy that had that king of shadows (Rembrandt) lived at Sheffield he would have been a frequent visitor at the "Cyclops," or the "Atlas," and have etched many a record of their mighty fires. To those of you who are only commencing to tread the paths of art, I would say, Work, embrace every opportunity of study that presents itself, and though you may never win a prize, never have your name enrolled among the great ones, you will have a rich reward in the trained eye and mind, with which you can drink in the beauties

of the Greek Theseus or the Moses of the great Michael Angelo, you will learn to understand the grandeur of Turner; and last, but certainly not least, you will gaze on the flowers of the garden, the grass of the field, the gem of the mine, with fresh interest; and as you see the setting sun paint the clouds with crimson and gold, you will be fain to exclaim with the great word-painter of Israel, "How manifold are Thy works. In wisdom hast Thou made them all; the earth is full of Thy goodness."

PRACTICAL NOTES ON PLUMBING.*

IX.

By P. J. DAVIES, H.M.A.S.P., &c.

BENDING BY SPLITTING OR SPLIT-MADE BENDS.

THIS method of bending is much practised in the provinces, and, for anything I know to the contrary, is one of the best methods in use, as by it you are likely to get a good substance of metal on the back of the bend whether the plumber be a good or a bad workman. Proceed as follows:—Cut the pipe down the centre to suit the length of your bend, as shown at A B,

Fig. 44. It will be quite as well if you first set out this bend on the bench, then you may measure round the back, as from C to L, to obtain the distance of the cut, which should always be three or four inches longer than the bend. You may also in this way obtain the correct length for the throat, GHI; here you will see that you have a quantity of lead to spare, i.e., from A to E, all of which has to be got rid of in uncut bends—some plumbers shift from front to back, but how many? Not one in twenty. After you have cut the pipe, open the throat part, bend out the sides and pull this part round a little at a time, then with a dummy, Fig. 38, work the internal part of the throat outward to as nearly the shape as you can. Go carefully to work, and do not attempt to work up the sides, ADB, until your throat is nearly to the proper shape, after which you may do so with a small boxwood dresser or bossing-stick. (It is not necessary to explain minutely what a boss or dressing-stick is, as they can be bought at almost any lead-merchants—the dresser is shown at E, Fig. 1, the bossing-stick is somewhat similar, the only difference being that it has a rounded face instead of flat.) Keep the dummy up against the sides when trueing it. If you have proceeded properly with this throat part, you will not require to work up the sides or edges, as in working the throat back, the sides will come up by themselves. Next take the back, pull it round a little at a time, the dummy being held inside, with your dresser work the two edges and sides slowly round, and the back will follow. Never strike the back from the underside with the dummy. After you have made a dozen or two you will be able to make them as fast as you please, but do not hurry them at first, as the greater part of this work is only to be learned by patient application, perseverance, and practice.

After you have made the bend it will require to be soldered, but before you can do this you must have the joint quite perfect and the edges true one with the other. A good bender will not require to touch his edges at all, but a novice will have to rasp and trim them up so that they come together. Having your edges true, soil them, take a gauge-hook to be obtained at Back the tool-maker's, which may be

described as a shave-hook with a gauge attached, and shave it about $\frac{1}{16}$ in. each side, now solder it to look like the solder A, Fig. 45, which

is done as follows:—With some fine solder tack the joint at ADE, Fig. 44, put on some resin, and with a well-heated copper-bit drop some solder roughly on the point from B to A, then draw the bit over it again to float the solder, being especially careful not to let the joint open when coming off at A. Some plumbers think fit to begin here, but that is a matter of no importance. Do not forget that if your joint is not properly prepared, that is to say true and even, it is sure to be a failure, and will have a "higgledy-piggledy" appearance. Some difference of opinion exists as to the best method of making these joints: one workman will make a good joint by drawing it, while, on the other hand, another one will do it equally well by wiping it. Drawing will be fully explained in a chapter on pipe-making. It may, however, be here mentioned that it is a method of making the joint by floating the solder along the joint with the hide and plumbing-iron.

It is not uncommon for plumbers to make their bends with only one joint on the back.

PULLING UP BENDS.

In London, it is the favourite plan to make bends without cutting them. Fig. 46. It is

done by taking a length of pipe and, just where you require the bend, lay it (with the seam at the side) upon a pillow, made by tightly filling a sack with sand, wood-shavings, or sawdust; have some shavings ready to hand and a good bath, also a short length of mandrel about 3ft. long and about $\frac{1}{16}$ in. smaller than the pipe, and a dummy as shown at A B, Fig. 56. Now, all being ready, put a few burning shavings into the throat of the bend, just to get heat enough to make it fizz, which you can judge by spitting on it. When this heat is acquired withdraw the fire, and let the labourer quickly place the end of the mandrel into the pipe, and pull the pipe up while you place a sack or anything else convenient across the throat of the bend, then pull the pipe up a little, just sufficient to dent it across the throat. Now, with a hot dummy, dummy out the dent, until it is round like the other part of the pipe. Keep at this until your bend is made, occasionally turning the pipe on its side and giving it a sharp blow on the side with the soft or hornbeam dresser; this is when the sides run out as in Fig. 37. Never strike the back part of the bend from inside with the dummy, but work the lead from the throat to the back with a view to thickening the back.

SET-OFFS.

A set-off is nothing more than a double bend, as shown at Fig. 47, and made in much the same manner. D is the long end of the pipe. Always make this bend first and pull it up quite

square, as it will be found to go a little back when pulling up the other bend; if you can make the two together so much the better, as you can then work the stuff from the throat of

one bend into the back of the other. The different-shaped dummies are also here shown: F a round-nosed dummy, G a double bent dummy, H a single bent, I straight, J hand-dummy, A B N a long bent dummy shown at Fig. 38.

BAD BENDS.

These can always be detected by examining them in their backs, as at Fig. 48; take a small

dresser and tap the pipe a few times round A B D to test for the thickness. Strike it hard enough to just dent it; next strike the back part of the pipe E with the same force, and if it dents much more it is not an equally-made bend. I have seen some of these much-praised London-made bends that could be easily squeezed together by the pressure of the thumb and finger. N.B.—Care must be taken not to reduce or enlarge the size of the bore at the bend.

BAD FALLS IN BENDS.

The fall given in bending lead pipes should be considered of quite as much importance as making the bends of equal thickness, especially for pipes, as shown in Fig. 49.

In this Fig. you have a drawing of a bad bend.

From A to B there is no fall whatever, as also from B to C; such bending is frequently done and fixed in and about London, which is not only more work for the plumber, but next to useless for soil-pipes. Fig. 50 shows how this bend should be made with a good fall from A to J, also from M to N; the method of making these bends requires no further explanation. R, P, and K are the turnpins for opening the ends, the method of which will be explained in future paragraph on "Preparing for Fixing."

BENDS MADE INTO TRAPS OR RETARDERS.

It will sometimes be found requisite to retard the flow of water when running through soil or other pipes, or to direct it to another course.

or even to form a trap in the length of pipe. This has been done in many ways, but Figs. 51 and 52 represent the method that I, after mature

working the dummy is also taken advantage of in working up embossed vases, &c.

(To be continued.)

THE ARCHITECTURAL ASSOCIATION AT WORCESTER.—I.

WE give to-day, among our illustrations, a selection of drawings which may add to or awaken some interest with regard to the excursion of the Architectural Association, which takes place next week, embracing Worcester and the neighbourhood. Our plates include a view from the south-east, showing a sketch, not before published, of Tewkesbury Abbey, giving a near drawing of the apsidal chapels and central tower, by Mr. A. J. Style, architect. Below will be found a plan illustrating the restored arrangement of the choir, transepts, and nave, in course of progress, from the designs of the late Sir Gilbert Scott, R.A., by his son Mr. John Oldrid Scott, to whom we are indebted for the plan. The two tints of the drawing indicate the two chief periods of work remaining, the Norman work of the nave and transepts being shown by the black sections, while the 14th-century "Chapterhouse," with chapels round the sanctuary, are shown by the lightly-hatched-in walls, and a reference too is added explaining the details of the plan. The nave was commenced by Robert Fitz-Hamon, the first Norman Lord of Gloucester, and nephew, by marriage, of the Conqueror, and it is, no doubt, to him and his successors that the mass of the present existing structure is due. In 1178 the monastic buildings were burnt, and traces of this fire are said to be still distinctly visible on the adjoining walls of the church. No remains of any buildings, such as would have been re-erected at this date (Henry II.) now exist. In 1219 Abbot Peter built the dormitory and back offices, which work has also been destroyed. Prior Sipton rebuilt the chapel of St. Nicholas in 1237, on the site of the present chapter-house (A) and original east apsidal chapel of the north transept, which latter corresponded with that on the south still remaining. The most important work, however, erected during the time of the Clares in the thirteenth century, was the supposed Lady-chapel of that date, extending beyond the north face of the north transept, and held by some to have been used rather as two chapels dedicated either to St. James or St. Nicholas and to St. Eustace. This building was somewhat singular on plan, resembling, in fact, a small church with nave and chancel. The first Lady-chapel of Norman date was of very small dimensions, forming one of three little apsidal chapels ranging round the original apse of the contemporary sanctuary. During the twelfth century the vastly-increased interest of all classes in the worship and public services of the Church was in every way conducive to the popular enthusiasm in honour of the Blessed Virgin Mary. The increased demands for such a manner of worship soon rendered the earlier Lady-chapel quite inadequate, and a second for general use was erected, the old eastern Lady-chapel being retained for the services of the monks. Some five years ago Mr. Blashill, assisted by Messrs. Collins and Cullis, the contractors working under Sir Gilbert Scott, made a series of excavations, and several doubtful points were then cleared up as to the size and character of this much-disputed building. Lady-chapels in monastic buildings have, in several instances, been used by the laity, and in these the difficulty occasioned by so public a use and want of easy access has been partly overcome; but there are others in which an eastern position for the general Lady-chapel was, no doubt, abandoned for this reason. Durham has been quoted, the Galilee built at the western end of the Cathedral being used as a Lady-chapel. The Lady-chapels at Worsop Priory and the Abbey of Bury St. Edmund's, are instances, too, worthy of remark, being placed on the easternmost sides of the transepts farthest from the monastic buildings. The 14th-century Lady-chapel at Ely is also a good case in point of such a plan. An existing chapel at Tewkesbury prevented such an arrangement there, and so it has been argued that the remains now seen of thirteenth-century date, already referred to, show the second and more important Chapel of Our Lady. The "Annals of Tewkesbury" record: "The Church of Tewkesbury was dedicated (in 1233) with the major altar, in honour of the

glorious Virgin Mary," referring evidently to the work then erected, and so like a separate church on plan.

The authority above referred to thinks that the Chapel of St. Eustatius, built by Prior Henry de Banbury in 1246, was placed between the eastern part of the new Lady-chapel, and the north side of the choir, and extending over the site of the old apsidal chapel, being entered by the ancient archway of that chapel now blocked up, and so shown on our accompanying plan. The sanctuary, with ambulatory round, and the three chapels already spoken of, at the commencement of the 14th century remained very much as originally built, the chief additions being on the north side, as just described. The period of the Clares terminated in 1314, when the last male of the line of De Clare was buried. His eldest sister Eleanor was married seven years later to Hugh de Despenser, Earl of Gloucester, and favourite of Edward II. During this period of the Despensers, several extensive works were carried out, chiefly by Sir Guy de Brien, who died in 1490. The increased wealth of the community and benefactions of the time sufficiently account for the considerable enlargements to the ambulatory, and the number of altars in the choir. The north wall of the transept failing, caused the destruction of the "Lady-chapel," and that which was not so destroyed was taken down at this time to the springing of the vaulted roof, and this is the building known as A on our plan, said to have been the chapter-house. However this may have been, this building was for some time appropriated for secular purposes after the Dissolution, and at one period was used as a free school. Sessions were held here, and Archbishop Laud, in his "Defence," complains of this. The form taken of a chevette with chapels radiating, as at Westminster, round the sanctuary, is a most uncommon arrangement in the county; indeed, these are perhaps the only two instances remaining where such a plan was adopted. The old choir does not seem to have been removed till after the chapels now seen were completed, and hence their low elevation. When the clerestory was built, the old circular columns were raised by two courses of stones, and 14th-century arches erected upon them, the upper portion of the present choir with its large traceried windows bearing the impress of a rather later period of 14th century work. The nave, tower, and transepts were vaulted at this time, the bosses of the former containing some beautiful carvings illustrative of the life of our Lord from the Nativity to the Majesty. That representing the Crucifixion is remarkable, for it showed the Crucifixion without a cross. This deficiency Mr. Gambier Parry has supplied in colour at the time he decorated the roof. The arcades and windows, originally visible from the crossing in the tower, are now hidden by the present ceiling, which is of the above date. The large eastern Lady-chapel, erected beyond the site of the original Lady-chapel, was a most elaborate and beautiful building of Early Perpendicular character, contemporary with the new work of the cloisters, traces of which exist on the south wall of nave. It was destroyed after the Dissolution of the Establishment, but enough remains to give evidence of its date and connection with other pages in the history of this noble abbey church. Trinity Chapel, shown by Fig. P, on our plan, was built by the widow of Edward, nephew of Hugh Despenser, who succeeded De Brien, already named. It is a small elegant structure for the celebration of the Mass. The figure of Edward kneels under a rich canopy, the fragments of a sculptured representation of the Holy Trinity still forming part of its considerable remains of carved work. In 1397, Abbot Parker built a similar chapel over the tomb of Fitz-Hamon, the founder (see Fig. K,) on the north side of the sanctuary. The remarkably fine, though much mutilated, tomb and chantry-chapel, Fig. I, is the last of the more elaborate memorials in the church. It is to the memory of Richard, Earl of Bergavenny and of Worcester, who died in 1411. The memorial was erected by Isabel, his widow, who became Countess of Warwick by her marriage with Richard Beauchamp, and hence the chapel has obtained the misleading name of the "Warwick Chantry." Several other more or less perfect tombs of abbots and other memorials remain of historical rather than architectural interest. The great gateway forms the most important

consideration, think most preferable. There is nothing new about this style of bending, as it has been long in vogue with provincial plumbers, but more especially in Kent. For many years it has had a run as a sink and slop closet-trap. Mr. Baldwin Latham, in his "Sanitary Engineering," says it was introduced and has been used for the Surrey and Kent sewers from about 1848.

I have also noticed many of these traps in the Sanitary Exhibition at South Kensington, made by Graham and Fleming, plumbers, who deserve a medal for their perseverance and skill, not only for the excellence of their bends, but also for some other branches of the trade, such as joint-wiping, &c., which is unquestionably the best work sent into this exhibition—in fact, quite equal to that which was shown at the exhibition of 1862. I shall treat further of these bends in an article on fixing, in a future chapter.

BENDS MADE WITH THE "SNARLING DUMMY."

This is an American method of making lead bends. Fig. 53 shows a dummy made upon a

bent steel rod, fixed into the bench. The method of working it is by first pulling up the bend, and to get out the dents, strike the rod of the snarling dummy, as shown at A, and the reaction gives a blow within the bend, throwing out the bend to any shape required. This method of

remains of the monastic buildings. Architecturally considered, the Abbey of Tewkesbury ranks with the great conventual churches of Gloucester and Pershore, the most striking characteristic of these three sister-churches being the use of very lofty and large round columns in the nave-arcades, surmounted by a low and inconspicuous triforium, while in the choir the reverse of such an arrangement is the rule, the columns of the arcade being remarkably low, and the triforium particularly lofty and distinctively important. The now conspicuous evidence of later works greatly obscure this curious arrangement, more particularly at Pershore. At Gloucester, the original proportions are still in existence, and they are still clearly discernible at Tewkesbury. The very unique west front of the nave will be remarked by the visitors next week, being occupied externally by one enormous arch recessed in seven orders of shafts, and reaching from the ground-line to the top of the church. The seventh order was discovered by Sir Gilbert Scott bedded in the wall. The present window, which doubtless occupies the position of several small windows of Norman date, was put up in 1636. The Norman pinnacles and turrets which terminate the angles of this west front are worthy of note, and they are also of peculiar design. The building is larger than Hereford Cathedral, and only just smaller than Gloucester. The few stalls, apparently of Late 11th-century date, remaining are among the present fittings, as also are the sedilia and remnants of the reredos, while the clerestory windows retain much of their beautiful and old stained glass. About £5,000 has recently been spent, under the direction of Sir Gilbert Scott, £3,000 in extensive reparation having been spent during the years 1824 and '30 chiefly in strengthening the Norman tower and transept walls. About £6,000 is estimated to be the required sum for the finishing of the necessary restorations.*

Our other sketches illustrate the Hall of Community and the Deanery, formerly the bishop's palace.

The Community, or Hospital of St. Walstan, retains in its hall, shown by Mr. Aston Webb's sketch, a very interesting remnant of Late Gothic woodwork, with its balustrade of still later date. It is situated in Sidbury, which leads from the Elgar tower over the canal. Originally the hospital staff consisted of a master, chaplain, and four poor brethren. Founded and endowed with considerable possessions in the 11th century, it was seized by Henry VIII. in 1515, and sold to a Worcester clothier, one Thomas Wyld, for £498! The large handsome Perpendicular window, with the repetition of "Emmanuel" on its "glass windowe quarrelles," is to be noted in the Hall, which is the principal apartment now remaining. It is, at present, used as a college for blind sons of gentlemen. The plans of the old bishop's palace, now part of the Deanery, and which commands a fine view of the Severn, are given on our other sheet. They were made by Mr. Sydney Vacher for Lord Alwyn Compton, the Dean, who has kindly placed them at our disposal. The carvings of some of the corbels and bosses in the crypts are very good, and these we shall illustrate in another number. The principal front of the Deanery was built by Bishop Hough in 1723, and bears his arms impaled with those of the See. George III., during his visit to Worcester in 1788, resided here. Mr. Vacher's sketches include some half-timbered bits from Worcester, which are numerous in Friar and Lich-streets, and the old Hostelry near the Old County Goal. The Bay from Tewkesbury is a good example of its kind. Eckington Church, the tower of which is given, is not far from Wellis Hall, ten miles south of Worcester, which building will be visited on Wednesday, when Mr. Thomas Drew, R.H.A., will act as guide.

MORTAR.

VERY different are the views held by architects on this subject. By many it is said the mortar ought to be used immediately after it is

made; other authorities assert that it cannot be kept too long if it is kept moist, and worked up with water. Fresh mortar cracks, but by keeping it for some time this property disappears, and better work is insured. Sir Edmund Beckett gives some practical advice on mortar, and refers to the value of adding brick-dust, which gives it almost the strength of cement, as it then contains the burnt clay found in cement. The bricks are best ground in a pug-mill, and Vitruvius advises that about one-third of the sand should be the proportion introduced. Much of the mortar used about London is nothing but a mixture of road-scrappings and asphalt refuse, with lime of a very inferior quality. One sanitary authority who has written on the subject of defects discovered in houses of large towns, cites a case in which 60 new houses were erected without a single load of clean lime the mortar and plaster being made of lime which had done duty in tan-pits and was full of animal refuse. Ashpits furnish too often the material which ought to be supplied by clean sand or mill-cinders. There is surely enough sharp road-dust to be obtained for mortar-making, though it ought to be well cleaned. Sharp clean road-drift makes excellent mortar, and is superior to most sand for stucco-work. Another valuable material entirely overlooked which is found to increase the strength of mortar is the ashes from smith's forges, and these ashes introduced in red brickwork jointing, have the effect not only of adding to the hardness of the mortar, but to the appearance also. Substances of these kinds are as easily to get as the ash cleanings and earthy matter with which half our houses are now built in large towns.

HYDRAULIC WORKS.

SOME very useful information will be found in Mr. Matheson's Aid-book in reference to pile-drivers, air-lock bells, cylinders of brickwork, &c., which may be of service to contractors and engineers. We therefore give the gist of some of the remarks on these heads, referring the reader to more comprehensive treatises for other details. The portability of pile-driving machines ought to be one of the chief considerations for those who are preparing for new works. They should be light and capable of easy adjustment—as they have to be pushed forward on an overhanging stage—but strong enough to lift piles into position. For very small works "ringing machines" are chiefly used, the weight being lifted by a hand-rope and worked by single power, that is, there is only one multiplication of power. For every multiplication the speed of course is reduced. The "telescope pile-driver" combines portability with strength, and drives diagonal as well as vertical piles. A "ringing machine" is often sufficient for driving the advance piles of a work, and it can be worked from a barge. On these piles a staging for a heavier machine can be constructed. In driving piles, accuracy is insured by attention to the pointing of the pile. Gauge piles for staging should have diamond-shaped points, that is, the pile should be tapered truly on all the four sides, so that the point should be true with the centre line of the pile. An unevenly-pointed pile can never be driven vertically. For sheet-piling the points are bevelled on one side so as to make them drive against the previous pile and make a close wall.

Pile-driving machines are generally from 35 to 10ft. high, and a manual machine has a base of about 8ft. square. With a 15cwt. ram such a machine cost about £50 to £60. Steam machines cost, Mr. Matheson says, from £250 to £350, or about £10 less if the woodwork be omitted for export. These are usually 40ft. high, with a base of 8 to 10ft. square, and weigh 6 to 7 tons. "A heavy ram and moderate fall will often do more effective work than the same aggregate force with a lighter ram and greater fall. On the other hand, the energy of a heavy ram may be expended in crushing the pile instead of forcing it downwards"—a remark which the engineer will appreciate. To determine the weight and fall of ram, for a certain purpose, the size of pile and the timber it is made of, no less than the hardness of ground, must be considered. In contract for pile-driving it is better to specify a price per pile, and then a rate per foot of depth, as the staging is generally costly, and every foot driven adds to the expense. Air-lock bells are now frequently used in laying

subaqueous structures, preparing foundations, &c. They are a kind of diving-bell having a working chamber at the bottom, but open, and filled with compressed air, of force sufficient to hold back the water. From this open air-chamber a large cylinder ascends to above the surface of water, which also gives access to and means of exit from the air-chamber. In this tube, at a certain position, is the air-lock, with a door and air-cock at top and bottom, by means of which communication is made with either the air above or the compressed-air chamber below. The natural buoyancy of the air-lock bell enables it to be adjusted easily. The air-cylinder differs only from the air-lock bell inasmuch as it can be converted into a bridge pier and permanently retained. There is a working chamber, protected by an air-lock, in which the excavation is carried on to a good foundation. After this is accomplished, the chamber and cylinder above are filled with concrete, the air-lock is removed, and the cylinder remains as an iron column or pier. The cylinder is weighted down by iron or stone, or better, by filling up a portion of it internally all round with concrete or brickwork. The air-caisson is on a similar principle; the bed is excavated by means of an air-chamber, it is then filled up with concrete, and a solid pier of concrete or masonry is built upon it, the tube and air-lock being removed. One of the largest air-caissons was constructed for the foundations of the St. Louis bridge over the Mississippi, where the air-chamber was 82ft. long and 62ft. wide. It was found that the air-pressure at a depth of 120ft. proved fatal to the workmen; that at a depth of 80ft., healthy men could work for an hour at a time, and this depth is considered as great as can be borne. Sand has been removed by air-pressure through a pipe without any difficulty, and we may refer the reader to detailed particulars of air-lock bells and cylinders sunk upon this plan, which have been described in this journal.

GREENOCK NEW DOCK AND MUNICIPAL BUILDINGS.

THE ceremony of laying the foundation-stone of a large new dock and of extensive new municipal buildings for the borough of Greenock, took place on Saturday last. The works at Garvel-park, which are at present in course of construction, will, when completed, have a frontage to the River Clyde of about one and a quarter miles, and comprise the Western Tidal Harbour, the "James Watt" Dock, the Northern Tidal Harbour, four graving docks, and the Eastern or great Tidal Harbour. The Garvel Graving Dock was commenced in 1870, and opened in April, 1874. The water area of the Western Tidal Harbour will amount to seven acres when completed. At present a portion only of this harbour is being constructed, having a length of quays of 1,150ft., with a depth of water of 35ft. at high water, or 25ft. at low water. The "James Watt" Dock will be 2,000ft. in length, 300ft. in breadth for about one-half of its length, the other half being increased to 350ft. where a jetty 800ft. in length and 90ft. in width will be constructed. The depth of water in the dock will be 32ft.—a depth, it is anticipated, sufficient to accommodate the largest class of vessels ever likely to be built. Its area is 14½ acres. There will be two entrances to the dock—one from the Western Tidal Harbour, and the other from the great harbour.

The municipal buildings are situated in the neighbourhood of Cathcart-square and Dalrymple-street, and include a new town-hall and all other rooms required. A tower will rise from the hall 245ft. above street-level, and while space and comfort required for business have been provided for, the furnishings of the hall and suite will be artistic and elaborate. The police department on the east side of the town-hall will have every accommodation. The block of the buildings facing Hamilton-street will have a handsome suite of apartments for all municipal meetings, besides many other rooms and offices. These will be on the upper floors, and the ground-floor will be occupied by handsome shops. There will be a piazza running along in front of the shops, with pillars of polished red granite. In the portion of the buildings facing Taylor's-close and Wallace-square, there will be the Chamberlain's office and other offices in connection with the Rates-hall. The buildings are being contracted for in three sections. The principal works of two of these have been let,

* A double page view, drawn by J. McDaniel, and exhibited at the Royal Academy, showing the Gilbert Scott restorations in interior view of Tewkesbury Abbey, was given in the BUILDING NEWS, May 14, 1877. A plan of Worcester Cathedral and its precincts was published in the same paper, March 2nd, 1876.

but the third section, which will comprise the Rates-hall and Harbour Trust offices, is not so far advanced.

CAMBRIAN ARCHEOLOGICAL ASSOCIATION.

THE 36th annual meeting of this association was held last week at Church Stretton, Salop, a town just outside the limitation implied by the title of the association, but the centre of a district rich in archaeological treasures, unrivalled in its class of hill scenery, and well served by railways. The proceedings on Monday week, the 1st inst., when an inaugural meeting was held at the town-hall, Church Stretton, under the chairmanship of the President-elect, Prof. Babington, M.A., F.R.S., F.S.A., who delivered an address upon the camps and other primeval fortifications which abound in Wales and other hilly parts of Britain. These works differed very materially, not only in strength, but in plan, from one another, and a superficial examination would show that it was not probable that they were all formed by tribes having the same degree of civilisation and advancement in constructive skill. Their names, too, were either legendary or merely descriptive—a proof that those who bestowed them were unacquainted with their origin. We could form no idea of how long a time had elapsed during which these rude fortifications of earth and stone were being made, but the marked differences in modes of construction seemed to show that each successive race of men which inhabited the country had its own mode of entrenchment, and that each successive race was more advanced in civilisation than that which preceded it. This accorded with what was learned from the study of the weapons, tools, ornaments, and fettle vessels obtained by excavations. They had the rude stone weapons of the palæolithic age; the more finished ones of the neolithic; the stone tools of a more recent age, some of which remained in use until shortly before the appearance of the Romans in Britain, notwithstanding the possession by the people of bronze and iron. There was evidence that the country was inhabited before the disappearance of the reindeer and other animals requiring the climate which existed when the mountain valleys had their glaciers. Several successive races might, and, indeed, must have lived in Britain before the arrival of the first wave of the Celtic people, the second wave of which still inhabited the country. Probably the existence of a Turanian race here would be generally admitted, and, doubtless, Theric tribes of Turanian race occupied nearly, if not the whole, of the west and south of Europe, until the arrival of the Celts drove the remnants of them into the extreme western parts, bordering on the Atlantic Ocean, where they were still represented by the Basques, and perhaps others. But even that was not enough; the west of Europe must have been inhabited long before the arrival of the Turanians by a race living in natural caverns and subsisting solely by the produce of the chase. Professor Babington proceeded to classify the several groups of remains, premising that very few were the work of the existing Welsh race. The older works he should arrange under four heads—1st, simple earthworks; 2nd, earthworks with simple stone supports and revetments; 3rd, drystone walls; and 4th, simple earthworks again. The earthworks were exceedingly common, and consisted of one or more banks of earth or stones, according to the nature of the ground, and external ditches. It was often impossible to distinguish their date or character. The second class were much more elaborate, and were intended for permanent occupation of a site, as they usually protected the water-supply, and had outworks for inclosing flocks in time of danger. Unfortunately these were often denuded of their stones for building purposes. A very accessible example of this class was Dinas Dinorwig, near the lower lake of Llanberis, and others might be seen at Din Slywy and Lligwy, both in Anglesea. The third class was composed of large ranges of drystone walls, nearly all of which were greatly dilapidated. Works of this class were by far the grandest and most interesting forts of which any remains existed in Britain, anterior to the Roman period, and in many cases there associated with them round or rectangular huts. The fourth class were the enormous dykes, the remains of which still

crossed the country in North Wales, Norfolk, Cambridgeshire, and Wiltshire. The annual report was then read and adopted, especial mention being made of the death of Mrs. Stackhouse Acton, of Acton Scott; Dr. Guest, F.R.S.; and Mr. Breeze, F.S.A.

Tuesday was spent almost entirely in Shrewsbury. The Castle, at one time the residence of Telford, who added the tower on the embankment, was first seen, and then the Council-house, c. 1620, and the grammar-school, many of the fittings of which, including the carved oak desk, are to be removed to the new premises at Kingsland. The fine church of St. Mary was described by Canon Lloyd, who showed how the original Norman building had been altered and enlarged by Early English and Perpendicular builders, the raising of the north aisle being due to the Puritans. Draper's Hall, the Guildhouse in Butcher's-row, a fine specimen of unaltered domestic work, and Ireland's Mansion, in the High-street, were also seen. An inspection of the town wall, and a long stay at the mutilated abbey, closed the afternoon's work. In the evening a meeting was held at Church Stretton at which Professor Babington gave a running commentary on the buildings seen during the day. The Rev. J. D. la Touche read a paper on "Stokesay Castle," and Mr. J. G. Dyke another on "Ancient Plough Marks on the Hills."

On Wednesday the members began work at the Church of Chureb Stretton, the principal feature of interest being the carved-oak reredos, a panel of which bears the date, 1667, but which, from the diversity of subjects, was declared by several speakers to have been "made up." On the way to Stokesay Castle the site of Norton Camp was seen, the castle being described by Mr. la Touche. The church, built in 1654, having been seen, the members proceeded to Ludlow, where the Rev. E. F. Clayton escorted the party over the great parish-church, which, although chiefly Perpendicular, exhibits remains of Early English and Decorated work and some traces of Norman. At the Castle Mr. G. Cocking acted as guide, and showed the principal rooms.

On Thursday the members proceeded by carriages to Much Wenlock, where, the museum and library having been seen, the Guildhall was visited, the records and charters, the carved panels, and old stocks being hastily glanced at before the members went to the Abbey. Mr. Gaskell, the owner of the house, showed the ruins, and also a holy well, which he has recently brought to light in the grounds. Train was taken to Buildwas, where the Abbey was seen under Mr. Leighton's guidance, and the excursion closed at Acton Burnell Church.

On Friday the members proceeded by rail to Shrewsbury, and drove to Haughmond Abbey, afterwards visiting Atcham and Wroxeter Churches and the Roman remains at Uriconium, returning to Shrewsbury to inspect the museum, which is rich in finds from Uriconium.

THE FURNISHING AND DECORATING OF SUNDAY-SCHOOLS.

A PAPER on this subject was read a few days since by Mr. F. Sharp at a meeting of teachers from two circuits of the Methodist Free Church. Art, said the lecturer, had made such rapid strides of late, and had had so refining an influence on the people generally, that it was now absolutely necessary to lift the standard of Sunday-schools in order that they might be on a level with the times. Generally a congregation and the building in which it worshipped corresponded—where they had a well-appointed church decorated with taste, they had an intelligent congregation. But it was strange that the same principle was not usually carried out in the school, the latter place having been largely kept in the background. The fittings of certain schools were described, and in every case there was shown to be lack of taste and judgment in the style of furniture, and a want of harmony throughout. In furnishing a school four things ought to be distinctly observed—harmony, simplicity, permanency, and comfort. After suggesting various items of furniture which he considered best adapted for the purpose (in the course of which as much attention ought to be paid to the comfort of the infants as to the older scholars), Mr. Sharp recommended that the walls both of class-rooms and the large assembly-room should be covered

with varnished paper—say of some neat geometrical pattern, and that on them should be hung the portraits of veterans who had been the support of their respective schools. Attention ought also to be paid to the lighting. The present (in many instances) unsightly gas-brackets should be replaced by pendants of bronze, and the jets should be covered with white globes, so as to have a more tempered and even light. The general effect of a school fitted according to these ideas would be to elevate the tastes of the scholars, and would aid in attaching them to the school.

THE WALL-PAINTINGS IN CANTERBURY CATHEDRAL.

AT the recent annual meeting of the Kent Archaeological Society, held at Canterbury, a paper on the wall-paintings of the Cathedral, and the means that are being used for their preservation, was read by Mr. James Neale, F.S.A., F.R.I.B.A., of Bloomsbury. He mentioned that arrangements were now pending by which it was hoped to copy in fac-simile the whole of the decorative paintings of the Cathedral and outlying buildings. These fac-similes could then be reduced by photography so as to insure the minutest accuracy and be published in a large volume similar to, but on a grander scale than, his work on St. Alban's. It was intended to give all the important plates in colour, and the rest by photolithography. When he mentioned that in the estimate already obtained, it was stated that some illustrations required as many as thirty different tints and that a separate stone was necessary for each tint, some idea might be formed of the immense labour and expense the volume would involve. However, there was reason to hope that the volume, when completed, would be an exceptionally valuable work, and would be the means of handing down for the study of future ages accurate copies of paintings, the originals of which might have disappeared. Some three years ago he commenced to copy in fac-simile the wall-paintings in the dark chapel of the Cathedral. Previously to his commencing the paintings, the Dean and Chapter had consulted Sir Gilbert Scott as to the best means to be employed to preserve these treasures, for, owing to the dampness, large portions of the plaster on which the paintings were, at various periods fell to the ground. Sir Gilbert died before the works were commenced. He (Mr. Neale) was consulted, and made a report to the Chapter. An examination showed the state of the painted plaster to be most serious, and if immediate means were not taken there was a risk of the whole falling to the ground. It was a marvel that so much was spared. The paintings were on a thin coating of plaster, which was strong and in good condition; but at the back of this outside plaster was mortar of about three inches thick. Owing to the wet and damp this mortar had become disintegrated. He suggested that the outside painted plaster should be lowered from its place, the loose mortar at the back removed, new cement supplied, and the paintings refixed. This plan was successfully applied to the vaultings, but not to the paintings in the stonework. The stonework was not intended for painting. At a later period when it was decided to decorate the chapel the smooth surface of the stonework was roughed so as to cause to adhere to it the thin coating of plaster on which the subjects were painted. The damp had got between the coating of plaster (half an inch thick), and the stonework, and was forcing away the plaster. The central part of one figure bulged out three inches from the stonework and was only kept from falling by the strength of the thin plaster and slight adhesion at the edges. Boards were placed in front of the picture, a small hole was cut above the head, and a thin solution of shellac was injected. The painting was then moistened by a solution and forced back into its original place. For some months the original solution gave a darker tone to the colours of the figure, but now he found that it was resuming its original colours. It was intended to put a varnish over the whole of the paintings as a means of preserving the colours from fading; but, seeing the unfortunate action of varnishes applied to wall-paintings in the Chapter House of Westminster Abbey and elsewhere, it was deemed wiser to try only a small portion and leave the rest uncovered to test the action of the weather and air. He found the

rain and snow coming through the unglazed windows adjoining the chapel did injury to the paintings, and the Chapter had them glazed. A lamp had also been kept in the chapel on damp days to prevent the fungus again forming. It was now over three years since the paintings were refixed; and he was pleased in examining the chapel last week to find the paintings in such excellent condition. Mr. Neale gave interesting descriptions of several of the pictures in the crypt; and made special reference to the painting of the legend of St. Eustace which occupied the whole of the easternmost Norman windows of the north and choir aisle. A thin coating of plaster was laid on the stonework and on this ground the subject was painted in distemper tints. In later days this painting with others in the Cathedral was covered with whitewash; and each successive time the Cathedral was whitewashed this painting seemed to have received its share, for in parts no less than fifteen coats of whitening were removed. This was done carefully, and he was much indebted to one of the vergers (Mr. Pugh) for help, and not only for actually removing much of the whitewash but for deciphering many of the figures. Many hours' work would expose, as an instance, what was thought to be a small tree. Mr. Sheppard's acute eye took this for a moakney, and such eventually it turned out to be. Another two days' work seemed to expose drapery in the King's footstool, but eventually Mr. Sheppard found the footstool to be the court jester. Day after day was spent in removing the whitewash, but those engaged in the work considered themselves well repaid, in being the means of bringing to light such an interesting subject. There was still some whitewash on the lower part of the picture. This, as soon as he obtained a little leisure, he was longing to remove and then complete his drawing.

HAGEN'S PATENT DUPLEX CESSPOOL TRAP AND CLEANSER.

THIS simple sanitary invention effectually prevents the stoppage of house-drains which so frequently occur, owing to yard sweepings, pieces of house-cloth, hair, rags, pieces of paper, tea-leaves, wood-chips, and other kinds of refuse being emptied or swept into the ordinary cesspool and washed down into the drain-pipes, there to accumulate and stop the flow of house-slops, and eventually necessitate the expense and annoyance of having the drains taken up and relaid, only to be again and again topped up. As will readily be seen from our

illustration, the drains can be kept open and clear for the speedy conveyance of the house-sewage, and the cesspool can be cleansed periodically by simply lifting out the "Cleanser," and emptying its accumulated contents into the dust-cart, instead of allowing the accumulated matter to give off malarial vapours and fever-disseminating smells. There is more actual merit in this simple little contrivance than in many a pretentious patent which has been puffed into temporary notoriety.

THE OLD AQUEDUCTS OF PARIS.

THERE have been three aqueducts erected in succession at Arcueil, over the valley of the Bièvre: the first between the years 292 and 300, by Constantius Chlorus, to supply the baths of his palace of Thermes with spring-water; the second, between 1613 and 1624, by the architect Brosse, at the order of Queen Marie de Medici, chiefly for the needs of her new palace of Luxembourg; and the third, between 1868 and 1875, by the engineer Belgrand, to furnish Parisians with spring-water of wonderful purity, gathered up at Champagne and led forty leagues for the wellbeing of the citizens. The last one—the gigantic aqueduct of La

Vanne—follows so nearly the course of the old aqueducts of Arcueil that the digging necessary for its construction brought to light the subterranean ruins of the Roman aqueduct, which was destroyed in the ninth century by the Northmen. It extended farther than the present aqueduct, which has its source at Rungis, and it has been traced as far as Chilly-Mazarin; and between Wissous and Rungis it has been found that there existed a manhole at the place of union of the feeders from whence the principal aqueduct started. As for the Arcueil aqueduct, it is just as Brosse constructed it, and although the water furnished by it is to-day of small consequence in the immense consumption of Paris, it is none the less curious to visit. To examine it properly one should begin at its origin at Rungis; from whence it is possible to walk through its subterranean course as far as the arches of Arcueil or even up to the fortifications. A unique thing to be seen at Arcueil is the collection of remarkable edifices of six different epochs, situated at a few steps from each other. Here the aqueduct of Marie de Medici ceases to be subterranean and crosses the valley on arches, and this monument is the Arcueil aqueduct properly so called. Upon this old structure of large quarried stones, erected by Brosse, Belgrand superposed the aqueduct of La Vanne of gritstone and cement. Immediately in front of the two central arches of the aqueduct of Louis XIII. there is still standing the face of a wall of the Roman aqueduct made of small dressed stones and courses of bricks. Between these ancient structures is partially set, in a small facade of the time of Henri II., of which only a portion can be seen, an elegant gate opening under an arch of the seventeenth century structure. The general aspect is extraordinary. Brosse's aqueduct is 1,245 feet in length, and has twenty-four arches—ten of them open, and 60 feet in height above the Bièvre. Belgrand's aqueduct, which surmounts it, is 3,245 feet long and has seventy-seven arches, and its total height above the same stream is 120 feet.

Belgrand in building the arches of the La Vanne aqueduct over those of Arcueil, in 1869, made two curious discoveries. At about 70 feet beyond the last manhole of the aqueduct he found, under the foundations of the structure of Marie de Medici, the Roman culvert of béton, in a perfect state of preservation, crossing the aqueduct at a right angle, so that, at this point, three aqueducts—La Vanne, Arcueil, and Constantius Chlorus—are actually superposed perpendicularly. In 1788, the engineer De Fer undertook the construction of a canal which, wherever it crossed private property, became a covered aqueduct. This was to have led to Paris a portion of the waters of the Bièvre, which were stored up at Amblainvilliers; but the work on it was for ever suspended during the succeeding year. At some feet beyond manhole number 14, at the point where the Medici aqueduct enters the ground, Belgrand found, on private property, and in juxtaposition with the Medici conduit, De Fer's covered aqueduct, so that, including La Vanne, three aqueducts are still united, and within a space of less than one hundred and fifty feet four of them are found.

The waters of the La Vanne aqueduct are carried over the arede in an enormous cylindrical conduit of béton, having an inside diameter of 7 feet, and which, kept constantly full, discharges a hundred thousand cubic meters of water into Paris every day. The Arcueil aqueduct (the portion of which between the fortifications and the Observatory has been removed and replaced by a cast-iron conduit) is now of secondary importance, and discharges its waters into the Pantheon reservoir, where they mix with the waters of the Seine.

BATTERSEA BRIDGE.

IT is often enough said nowadays, writes Mr. C. Bruce Allen, in the *Engineer*, that this is emphatically the "age of iron"; and there certainly can be but small doubt about it. It is so. All materials are giving way more or less before it, and most certainly that material which once on a time, as in Gothic days, was in as much request—viz., timber. Examples there are all about us of this wooden or timber building, as it was in many ways; but in nothing is the change of material as a means of construction more notable than in the item of bridge-building. Old London Bridge, as at first, was of wood; and the present Battersea and

Putney Bridges, even to this year of grace, are of wood. They are both of them not a little picturesque; but they are doomed to pass away, and give place to the all but, in an engineering sense, ubiquitous iron. Battersea Bridge, which has so often figured in pictures, and in *libres studiorum*, and otherwise, is as all know, to give place to one of iron. These wooden structures over Thames River were, and are, very ingenious specimens of pure timber construction. There is certainly no attempt at architecture or ornamentation, of any style or kind; and yet, the simple constructional and engineering lines are singularly picturesque; and thus does a sort of kind of "timber architecture" grow out of it, and is seen in it. This is not a little noteworthy in these days of transition; for what a curious thing it would be to see an iron bridge worked out in the like way. For those now built over the Thames—as at Westminster, and the Blackfriars Railway Bridge—are imitations of stone constructions, and with ornamental details borrowed from a distant past. That the metal iron is taking the place of wood is certain, but when shall we see an iron architecture, as in a bridge, as we see in the past of things architectures of stone and wood?

PARKES MUSEUM INTERNATIONAL EXHIBITION AWARDS.

THE following are the awards made in those sections wherein our readers are more immediately interested:—

SECTION XIII.

DOMESTIC AND HOSPITAL ARCHITECTURE.

PLANNING, CONSTRUCTION, DECORATIVE MATERIALS.

JUDGES.—Sir Joseph Fayer, K.C.S.I., M.D., F.R.S.; George Atchison, A.R.A.; Fred. J. Mout, M.D., F.R.C.S.; Edward C. Robins, F.S.A., F.R.I.B.A.; P. Gordon Smith, F.R.I.B.A.; Professor Thomas Roger Smith, F.R.I.B.A.; Henry Saxon Snell, F.R.I.B.A.; Alfred Waterhouse, A.R.A.

FIRST CLASS.

Robert Adams, 335, reversible windows and adjustable door springs
Henry Boulton and Co., 253, art stoneware
Charles Drake and Co., 361, marble concrete
Capt. Douglas Galt, C.B., F.R.S., 54, hospital plans
Howard and Sons, 442, parquet flooring
Ibilee and Horn, 328, Balmain's luminous paint
Russell and Erwin Manufacturing Company, 394, locks and lock furniture
Mons. Tollett, 91, hospital plans
Wilecock and Co., 279, architectural glazed ware
T. Worthington, F.R.I.B.A., 54, hospital plans

AWARD OF MERIT.

Albissima Paint Company, 390, white paint
Artisans', Labourers', and General Dwellings Co., Limited (Rowland Plumb, architect), 60, plans of dwellings for artisans and labourers
Lawrence Booth, F.R.I.B.A., 65, plans for dwellings
M. Eordian, 89, plans for warming and ventilation of public buildings
Bryden and Sons, 393, bell-hanging apparatus
Candy and Co., 391, damp-proof bricks for building and paving
Coe and Robinson, architects, 67, hospital plans
J. Finch and Co., 302, Bisque glazed bricks and other building materials
Grantham, jun., and Denton, jun., 92, designs for abattoirs
Hobbs, Hart, and Co., 422, locks and safes
Maguire and Co., 282, oxidised iron (Barff's process)
G. E. Pritchett, F.S.A., 248, corrugated ventilating pipes, and system of construction
Silicate Paint Company, 257, washable distemper
Smith and Turner, 397, door-springs, water-bars, and bolts
A. Smith and Stevens, 425, sill bars and casement bolts, spring hinges, door knobs, and locks
Spence's Metal Manufacturing Company, 354, Spence's metal
James Stiff and Sons, 255, art stoneware vases, &c.
W. Tonks and Sons, 242, sash and lantern fasteners and openers, steel sash lines, bolts, chains, and other door furniture, and wedge casement stays
E. Turner, F.R.I.B.A., 64, hospital plans
Fredk. Walton and Co., 288, wall decorations (Lincrusta-Walton)
Alfred Walker, 362, concrete flooring
Wortley Fire Clay Company, 365, glazed bricks and other building materials
W. Woodlams and Co., 439, non-arsenical wall and ceiling papers.

The following exhibits in this section were not considered in competition for awards, the exhibitors being judges, or otherwise officially connected with the Exhibition:—
Mark H. Judge, architect, 61, plans of three-room dwellings for artisans and labourers. Drawing for fireplace trimmer
Dr. G. V. Poore and A. Waterhouse, A.R.A., 59, plan for the reconstruction of University College Hospital
Edward C. Robins, F.S.A., F.R.I.B.A., 62, designs for hospitals and schools
Professor T. Roger Smith, F.R.I.B.A., 55, designs for hospitals
H. Saxon Snell, F.R.I.B.A., 56, designs for charitable and parochial establishments.

SECTION XIV.

VENTILATING, LIGHTING AND WARMING.

JUDGES.—H. H. Collins, F.R.I.B.A.; Captain Douglas Galton, C.B., R.S.; George Godwin, F.R.S., F.S.A.; Ernest Hart, M.R.C.S.; Professor Kerr, F.R.I.B.A.; J. P. Seddon, F.R.I.B.A.

FIRST CLASS.

Benham and Sons, 410, general excellence
Robert Boyle and Son, 258, general excellence
Chorlton and Dugdale, 411, "The Sunlight" stove
T. J. Constantine, 366, cooking range
Crossley Bros., 357, "The Otto Silent Gas Engine"
Frederick Dyer, 307, hot water apparatus
R. Renton Gibbs, 415, general excellence
Robert H. Griffin, 373, improved register stove
W. H. Hopkinson, "Libra lamp and valve"
S. Leoni and Co., 376, general excellence
Longden and Co., 428, "The Leeds stove"
Musgrave and Co., 412, general excellence
T. Potter and Sons, 420, "The Thermohydric" grate
G. E. Pritchett, F.S.A., architect, 248, heating and ventilating apparatus
Radiator Range Co., 431, "Radiator cooking range"
Rosser and Russell, 427, general excellence
C. R. Stevens, 383, hot-water apparatus
Strode and Co., 426, general excellence
Verity Bros., 416, "air propeller" and for general excellence
T. Waller and Co., 219, general excellence
J. Weeks and Co., 414, general excellence
Wilson Engineering Co., 444, cooking ranges.

AWARD OF MERIT.

Robert Adams, 395, ventilating window apparatus
J. L. Bacon and Co., 423, general excellence
P. Hieckes Bird, F.R.C.S., 378, ventilators
Frank W. Clark, 355, gas-machine
Comyn, Ching, and Co., 391, general excellence
Joseph Constantine, 374, warming apparatus
John Drysdale, M.D., and J. W. Hayward, 357, system of ventilation
Fredk. Edwards and Son, 417, general excellence
J. E. Ellison, 278, conical ventilators
Faraday and Son, 377, gas appliances
J. F. Farwig, 418, calorifier
Gilmore and Clark, 385, ventilators
William Hellier, 367, water-heaters
Harry Hunt, 429, "crown jewel" stove.
C. Kite and Co., 389, chimney top
Charles Portway and Son, 421, "tortoise" stove
Mrs. Priestley, 353, window ventilator
Ritchie and Co., 382, "lux calor" apparatus
Sanitary Engineering and Ventilation Co., 286, general excellence
Steel and Garland, 346, general excellence
Steven Bros. and Co., 259, general excellence
Thames Bank Iron Co., 280, general excellence
Wm. Tonks and Son, 242, Curral's ventilators. The architect ventilator.

SECTION XV.

WATER CLOSETS, SINKS, BATHS, &c., SEWAGE AND DRAINAGE.

JUDGES.—Professor W. H. Corfield, M.D.; William Eassie, C.E.; Rogers Field, M.Inst.C.E.; P. Thorne Thorne, M.B.; Ernest Turner, F.R.I.B.A.

FIRST CLASS.

Beard, Dent, and Hellyer, 254, "Artisan" water-closet with flushing rim and improved joint between basin and trap; valve-closet with flushing rim and ventilation to valve-box; cast lead S and P traps
Birmingham Sanitary Association, 271, Potts's Edinburgh air-chambered disconnecting trap
John Bolding and Sons, 247, simplex valve-closet, with flushing rim and water supply to overflow; bath, with quick waste and air-vessel
H. Braithwaite and Co., 347, siphon action water-waste preventer
W. P. Buchan, 211, Buchan's disconnecting drain-trap
Joseph Cliff and Sons, 270, enamelled stoneware sinks and baths
Henry Doulton and Co., 253, Stanford's joint for drain pipes; "Kenon" air-chamber floor and trap; locking water-waste preventing bath fittings
P. Dyer, 307, tidal valve trap
A. Emanuel and Sons, 331, siphon action water-waste preventer, with after-flush
J. Finch and Co., 302, Buchan's disconnecting drain trap; "royal" porcelain bath
Hayward Tyler and Co., 329, hopper closet, with flushing rim and trap, fitted with regulator and Chandler's waste-preventing cistern
Ingham and Son, 266, Stanford's joint for drain-pipes
George Jennings, 257, automatic flushing jar; "Dubois" drawn lead traps
Walter Macfarlane and Co., 25, excellence of iron-work
Moule's Patent Earth Closet Co., 317, Moule's earth closet, No. 9
J. Parker, 313, dry earth closet, self-acting without separator
J. Purnell and Son, 342, hopper closet with flushing rim
Shanks and Co., 281, spray and douche baths
H. Sharp, Jones, and Co., 341, Stanford's joint for drain pipes
Thomas Smith and Co., 269, Herbert Jones's drain-pipe
J. Tylor and Sons, 256, valve closet, with flushing rim, and without overflow connected with valve box; flushing urinal trapped in basin; waste-not closet valve; locking water-waste preventing bath fittings
E. G. Underhay, 326, regulator for valve closets.

AWARD OF MERIT.

A. T. Angell, 304, air-tight covers for air chambers and inspection shafts
Beard, Dent, and Hellyer, 254, disconnecting trap for soil pipes; disconnecting gully trap, with side inlets for rain-water pipes and sink wastes; siphon action flushing cistern; "Artisan" water closet and siphon sink combined; square enamelled iron slop sink; lavatory basin, with quick waste
John Bolding and Sons, 247, "National" Wash-out closet, with flushing rim; siphon-action water waste preventer; "Champion" trap
H. Braithwaite and Co., 347, wash-out closet, with flushing rim; Claughton's trap

Edward Brooke and Sons, 259, stoneware ribbed pipes for sewers
W. P. Buchan, 261, drain pipes with rest and access lid
Capper, Son, and Co., 332, Brian Jones's patent joint
Henry Doulton and Co., 253, Doulton's joint for drain pipes; stoneware grease trap; Latham's balance-valve drain flap; disconnecting gully trap, with reversible top and side inlets; Lambeth flush-out closet, with flushing rim; lipped urinal, with constant flow; "vacuum" water-waste preventer
C. W. Durham, 351, rigid construction of house drainage
A. Emanuel and Sons, 331, chain action water-waste preventer, with after-flush
Eureka Concrete Company, 263, concrete sewers in segments
J. Finch and Co., 302, porcelain sinks for butlers
Gillow and Co., 381, lavatories for limited space
Hayward, Tyler and Co., 329, urinals, with treadle action; Chandler's water waste preventer; shower and douche bath valves
Edward Howard, 306, Saxon Snell's automatic flushing and ventilating arrangement for water closets, &c.
Ingham and Sons, 266, balance valve flap; Brown's accessible disconnecting trap
George Jennings, 257, lipped urinals; anti-percussion bath valves; shampooing apparatus
Washington Lyon, 364, model of fixed disinfecter, by steam
Maguire and Co., 282, method of jointing drain-pipes; clean water flush tank; disconnecting trap; Dr. Scott's disinfecting stove
Henry Owen, 330, water-waste preventer
J. Purnell and Son, 342, white stoneware channels; Woodward's wash-out closet with flushing rim; siphon-action water-waste preventer
Wm. Ramsey, 352, Claughton's trap
Sanitary Engineering Company, 286, Weaver's drain disconnecting trap
Shanks and Co., 281, Bramah valve closet, with ventilation to valve-box; wash-out closet with flushing rim; cast-iron enamelled bath; bath fittings
C. H. Sharp and Co., 327, water closet for ships; earth closet
H. Sharp, Jones, and Co., 341, rock concrete tubs
The Shone Drainage, Sewerage, and Water Supply Company, 284, pneumatic sewage ejector
Steven Brothers and Co., 250, cast-iron enamelled bath
James Stiff and Sons, 255, Weaver's drain disconnecting trap; Weatherley single-dip disconnecting trap for sinks and waste water
T. Pridgin Teale, 1424, diagrams of defective sanitary arrangements

J. Tylor and Sons, 256, slop sink, with galvanised top and regulator-valve
John Warner and Sons, 333, valve closet, with flushing rim and movable valve seating
Robert Weare, 311, inodorous carbon closet commode
Wilcock and Co., 279, disconnecting gully; trough closet
James Woodward, 323, wash-out closet-basin with flushing-rim, and trap; hopper closet-basin with flushing rim and trap; porcelain sinks for refreshment bars
The following exhibits were not considered in competition, being invented by one of the judges:—
Bowes Scott and Read, 349, Field's flush tank; Field's annular siphon for flushing sewers.

SECTION XVI.

WATER SUPPLY AND FILTRATION.

JUDGES.—Lieut. Col. Frank Bolton; Prof. Francois De Chaumont, M.D., F.R.S.; R. B. Graitham, M.Inst.C.E.; Professor Prestwich, F.R.S.

FIRST CLASS.

E. and J. Gardner, 398, various forms of filters on Major Crease's (now Lieut.-Col. Crease, C.B.) patterns. Also "cariferal" filtering material
Silicated Carbon Filter Co., 402, filtering medium and filters, with asbestos strainer
Spongy Iron Domestic Filter Company, 404, water filters; spongy iron and prepared sand; earthenware filter cases with late improvements
J. Tylor and Sons, 256, waste-not valve applied in various forms for cisterns, closets, courts, and alleys.

AWARD OF MERIT.

John Bolding and Sons, 247, workmanship of cocks and valves. Specimens of workmanship in lead pipes made by Graham and Fleming
Defries and Co., 433, blocks of pumice and granulated carbon
Henry Doulton and Co., 253, manganous carbon filter (Berny's patent). Automatic aerating cistern filter (Bailey Denton's)
A. Emanuel and Sons, 331, deep well pumps, valves and cocks
Hayward Tyler and Co., 329, valves and cocks
George Jennings, 257, drawn lead pipes by Dubois
P. A. Maignen, 401, "Filtre Rapide," with asbestos cloth, &c.
Maguire and Co., 282, patent renewable filter
Quirk, Barton and Co., 372, tin-lined ear pipes
Sanitary Engineering and Ventilation Company, 286, cistern filters, portable filters, and table filters
G. T. Tonks, 243, glass balls for ball valves and frictionless balance supply valve.

SECTION XVII.

SCHOOL FURNITURE, WINDOW BLINDS, CLOTHING, BOOKS, &c.

JUDGES.—Mrs. Garet Anderson, M.D.; J. C. Buckmaster, E. North Buxton (Chairman of the School Board for London), Alfred Carpenter, M.D., Dr. J. H. Gladstone, F.R.S., W. A. Meredith, M.D.

FIRST CLASS.

Thomas Bradford, 441, washing machines
Coleman and Glendinning, 235, school furniture and appliances.

AWARD OF MERIT.

Robert Adams, 395, universal Venetian blinds
Brydon and Sons, 393, window-blinds and roller actions for sun-blinds
Larmuth and Sidebotham, 1009, school furniture and appliances

William Tonks and Son, 242, patent bookcase fittings; Hookham's patent picture-line and adjusting fasteners; Allen's registered hat-holder
Henry Tylor and Son, 238, appliances connected with window-blinds.

The Exhibition, which was opened on July 16th by Earl Spencer, will finally close tomorrow. The amount of public interest which it has evoked has been very considerable indeed, particularly among the professional classes connected with medicine, architecture, and sanitary engineering. In addition to the members of the Medical Congress, the Exhibition has been visited by the officers of local boards and other authorities from all parts of the kingdom, and the Government of New South Wales have appointed a commission to obtain some of the more important exhibits for the new Sanitary Museum now being established in Sydney on the lines of the Parkes Museum of Hygiene. As some indication of the amount of interest which has been taken in this Exhibition—the first organised by the executive committee of the Parkes Museum, outside its permanent collection at University College, we give the following statement of the number of visitors up to last Wednesday evening:—

Opening day	4,349
Total daily admissions by payment	11,973
Total number of season-ticket holders	1,729
Estimated number of members of Medical Congress admitted free	1,500
Estimated number of Fellows and other ticket-holders of the Royal Horticultural Society admitted free	2,060
Total number of visitors from July 16th to August 10th, allowing only for one visit by each season-ticket holder	21,542

WHITWORTH SCHOLARSHIPS.

THE following awards have been made of Whitworth Scholarships and Whitworth Scholarship Prizes by the Science and Art Department:—

LIST OF CANDIDATES SUCCESSFUL IN THE COMPETITION FOR THE WHITWORTH SCHOLARSHIPS, 1881.

Name.	Age.	Occupation.	Address.	Value of Scholarship.
Lousley, E.	26	Engine fitter	Wallingford	£200
Sutton, A.	21	Engine fitter	Brighton	150
Grace, R. W.	20	Engineer apprentice	Liverpool	150
Sharp, A.	18	Engineer apprentice	Glasgow	150
Wild, A. E.	20	Engineer apprentice	Manchester	125
Jordan, H. G.	23	Engineer	Manchester	125
Murphy, E.	21	Engineer apprentice	Liverpool	100
Perry Jones, R.	23	Engineer apprentice	Carnarvon	100
Richardson, S.	22	Draughtsman	Greenwich	100
Barendt, A. H.	21	Engineer apprentice	Liverpool	100
Herbert, C.	19	Mechanic	Oldham	100
Davies, E. J. M.	20	Engineer student	Bristol	100
Platt, T.	21	Millwright	Manchester	100
Savage, W.	22	Engineer	Crewes	100
Tyson, J.	25	Engineer	Liverpool	100
Haddock, A. G.	20	Fitter	Woolwich	100
Martin, W.	20	Engine Fitter	Brighton	100
* Equal.				

EXAMINATION FOR WHITWORTH SCHOLARSHIP PRIZES, 1881.

SCHOLARS APPOINTED IN 1878.

Marks obtained.

Name.	Theory.	Practice.	Total.	Prize Awarded.
Groves, W.	1,700	1,185	2,885	First prize, £100
Mather, T.	1,940	873	2,813	Second .. 60
Tozer, W. H.	1,365	1,066	2,431	Third .. 50
Needham, J. E.	1,943	444	2,387	Fourth .. 40
Duckworth, T.	1,186	419	1,605	Fifth .. 30
Kingdon, Z. H.	897	—	—	Sixth .. 20

* Specially excused from the Examination in Theory.

FINAL COMPETITION.

Marks obtained.

Name.	1879	1880	1881	Total.	Prize awarded
Groves, W.	2,126	2,595	2,885	7,606	First £200
Needham, J. E.	2,264	2,250	2,387	6,910	Second 100

A new Congregational chapel was opened at Mevagissey, Cornwall, on Thursday week. It is Gothic in style, and measures 60ft. by 40ft.; the materials are local stone and granite dressings, all the internal fittings, including partially open roof, open seats, gallery, and rostrum, being of varnished pitch-pine. The chapel seats 400 persons and has cost £1,650, but some of the material of the previous chapel which occupied the same site has been reused. Mr. Sylvanus Trevel was the architect, and Mr. B. H. Roberts, of Mevagissey, the builder.

The rural sanitary authority of Whitehaven last week elected Mr. George Clark, of St. Bees, as surveyor in the stead of Mr. John Kenney, deceased. There were 29 applicants for the post.

ILLUSTRATIONS.

THREE HOUSES ON THE CHELSEA EMBANKMENT.—THE DUCHANAN COTTAGE HOSPITAL, ST. LEONARD'S-ON-SEA.—ENTRANCE HALL, ST. PETER'S HOSPITAL, COVENT-GARDEN.—THE BISHOP'S PALACE, WORCESTER, NOW USED AS A DEANERY.—THE COMMANDERY, WORCESTER.—THE ABBEY CHURCH OF ST. MARY, TEWKESBURY.

OUR LITHOGRAPHIC ILLUSTRATIONS.

THREE HOUSES ON THE CHELSEA EMBANKMENT.

THESE houses are of red brick, of very good work, built by Mr. W. H. Laseelles. The architect is Mr. R. Norman Shaw, R.A.

THE DUCHANAN COTTAGE HOSPITAL, ST. LEONARD'S-ON-SEA.

THIS hospital is about to be built on a site at the junction of Springfield-road with the London-road, kindly given by C. G. Eversfield, Esq. The plan given shows the arrangement of the ground-floor; on the first floor there will be a convalescent-room for the patients and bedrooms for the matron and attendants. Externally the building will be faced with red bricks and rough-cast panels; the roofs will be covered with dark brown tiles. The architect is Mr. W. Hay Murray.

ENTRANCE-HALL AND STAIRCASE, ST. PETER'S HOSPITAL, COVENT-GARDEN.

THIS illustration shows the entrance-hall and staircase of the new Hospital of St. Peter, now being erected in Henrietta-street, Covent-garden, from the designs of Mr. J. M. Brydon, F.R.I.B.A. We illustrated the exterior of the building, and fully described it in our Midsummer Double Number of June 21 last.

ABBAY CHURCH OF ST. MARY, TEWKESBURY.—THE HALL OF THE COMMANDERY, WORCESTER.—BISHOP'S PALACE AND OTHER BUILDINGS IN AND NEAR WORCESTER.

DESCRIPTIONS of these illustrations will be found in our preliminary notice of the Architectural Association's Excursion on p. 195.

SKETCHES OF OLD DOMESTIC WORK IN ESSEX AND SUFFOLK.

I SEND the following descriptions of my sketches which appeared last week:—Panfield Priory, now a farmhouse, is situated about two miles from Braintree, in Essex, and was founded in the reign of William the Conqueror as an alien house of Benedictine monks, subordinate to the Abbey of St. Stephen, at Caen. Under Henry V. it became parcel of the possessions of the convent at Canterbury, and at the Dissolution it was granted to Sir Giles Copel. The interior has been grievously modernised, and sashes have been inserted in all windows on the other side to that represented in the sketch. A fine open roof existed over what was doubtless the hall, but floors and partitions have been inserted to fit it to its present use, and the tracery spandrels

and carvings of the roof patched together to serve as a sort of what-not. Doreward's Hall at Bocking, a parish adjoining Braintree and Panfield, was built in 1512, as the inscription over a window on the principal remaining front testifies. The remainder of the building, in the rear of the group of chimneys, is for the most part of much later date, and the whole is now a farmhouse. The family whose name it bears was, however, of earlier settlement here, for John Doreward built and endowed an almshouse as a "Maison Dieu" in Bocking, by license of King Henry VI. The motto, "Soli Deo honor et gloria," is inscribed in the spandrel with the date. Horham Hall, near Thaxted, is well known as the residence of the Princess Elizabeth at times during the reign of Queen Mary. It has been gradually reduced in size to meet more limited requirements. So lately as 1840 or thereabout, the chapel and a whole wing were demolished, yet enough remains in very good repair to show it to have been a very noble and beautiful mansion of Late Perpendicular date. In common with those just described and almost all others in Essex, it is built of red brick, with stone dressings used sparingly. The sketch at Clare is from the summit of the mound on which the remains of the keep of the very extensive castle stand. There is much to interest the architect and antiquary in the church, priory, and remains of domestic work still left in this little decayed market-town, whose secluded position seems to have saved it from the modernisations which have rendered so many towns of its sort so stale, flat, and unprofitable. The chimneys at Newport now adorn a small roadside farmhouse: the four stacks at Waltham belong to a village-shop adjoining the churchyard, which is reputed to have been the "Priest's house," and is credited with the possession of the usual subterranean passage. The "Crown House," at Newport, ostensibly takes its name from the crown in relief in the panel over the entrance. The stucco foliage in the panels with which the front is adorned is much damaged, and on the ground-floor has quite disappeared. Whether the crown has any reference to Mistress Nell's connection with the "Merry Monarch," who on one occasion, at least, visited Audley End, not far from Newport, I cannot say. The house at Whittle, now converted into several cottages, needs no description. The village, once a market-town on the much-frequented main road from London to Bury St. Edmund's and Norwich, is picturesquely built round a large green, and close by is the site, occupied by an orchard, of a palace built by King John in 1211, of which the moat still remains, though no stone of the building is to be seen. Of the subject of the sketch at Sudbury I could glean no history or tradition. Part is now uninhabited, the rest is scarcely habitable, and is fast falling to decay through neglect alone. The mouldings of the window-mullions, &c., are good, and the whole effect particularly pleasing. It is much to be regretted that something is not done, at least to preserve it from further ravages of wind and weather. Beeleigh Abbey, near Maldon, was founded in 1180 by Robert Mantell for Premonstratensian Canons, and dedicated to St. Nicholas. To this date belong the chapter-house and refectory with some smaller portions. The former is in a fair state of preservation, and with the refectory has a groined ceiling springing from slender Purbeck marble columns, in each case dividing the apartment into two aisles. Perpendicular windows were inserted in the refectory, one bay of which has been cut off at the north end for a living-room for a labourer's family, and a half-bay at the south end for a passage-way, leaving two and a half bays untouched. In this apartment are the remains of a good carved stone chimney-piece of the date of the windows. Above it is a dormitory with a good open roof, which the visitor is informed is of cedar, the proof given being that spiders will not make their webs among its timbers. Certain it is that no webs are visible, though usually such a roof would be festooned from end to end when untouched, and indeed out of reach of brooms. The half-timbered building in the sketch faces west, and adjoins the south end of the refectory, the chapter-house lying east and west at the north end of the same. I cannot help remarking that in Essex a wide and little-touched field lies open to the student of domestic work, presenting not only every variety of work, from simple cottages to the most splendid mansions, but possessed,

too, of the great advantage of lying within easy reach of the metropolis, both by railway, and, what is as great a consideration in our bicycling days, by road as well. F. W. WOODHOUSE.

CHIPS.

The new school-buildings lately erected in connection with the Ilkley Congregational School were opened on Thursday week. The new buildings are in the Gothic style, corresponding with the outline of the church, which was erected some eleven years since. The contracts amount to £3,000, but the whole cost of carrying out the scheme, including the alteration and renovation of the church, will be more than that. Messrs. Hargreaves and Bailey, of Bradford, are the architects.

The rebuilding of nave and restoration of tower to West Lexham Church, Norfolk, has commenced, Messrs. Hooks, of Titchmarsh being the contractors. The architect is Mr. G. T. Pedder, Holkham.

On the authority of Sir Henry Hunt, consulting surveyor of Her Majesty's Office of Works, the value of the unoccupied land at the Blackfriars end of the Thames Embankment is stated to have risen since 1870 from £40,000 to £81,825 an acre.

St. Mary's Cathedral, Sydney, New South Wales, now presents an altered appearance, owing to the rapidity with which the works have been carried on during the past few months. All the masonry of the outer walls of the main building is finished, and the inner walls are up to contract height. The great window and gables at the north end of aisles, together with the beautiful circular side windows, are completed, and look remarkably fine. The northern window much resembles the great window in Lincoln Cathedral, England. Everything in connection with the building is being pushed on with energy, and every effort is being made to have the new cathedral ready for opening in January, 1882.

The tender of Messrs. Pearson and Son, of Bradford, who have just completed the main sewerage of Ipswich, has been accepted for the construction of a new dock at King's Lynn, to have a water-space of eight acres. The existing Alexandra Dock at Lynn is about six and a-half acres in extent.

The foundation-stone of the South Devon and East Cornwall Hospital was laid by Earl Mount Edgumbe, at the Seven Trees estate near Plymouth, on Friday week. Messrs. Coe and Robinson, of London, whose design was selected in competition from nine, and was illustrated in the BUILDING NEWS for Feb. 20, 1880, are the architects, and Mr. Jonathan Marshall, of Plymouth, is the contractor. The hospital will accommodate 102 patients, and will cost about £17,000.

The new grammar-school at Saffron Walden was opened by Lord Colchester last week. Mr. Edward Burgess is the architect.

A meeting of the Tamworth parish-church restoration committee was held on Friday week, when a balance of £937 being reported to be promised, in addition to the £1,273 necessary to meet existing contracts; it was resolved to instruct Mr. Basil Champneys, their architect, to prepare plans for restoring the clerestory windows on north side of nave, and the three tower windows.

In our description last week of the new Edinburgh Dock at Leith, we omitted the names of the engineers, Messrs. A. M. Rendel and George Robertson.

On August 1st the corner-stone of the extensions to Mauldeth Hall, Heaton Mersey, near Manchester, was laid by Mr. Richard Armistead. The hall and grounds were bought by the committee of the Northern Counties Hospital for Incurables for £15,000, and the hall is being altered and extended at an outlay of £6,800, to accommodate 100 patients. The architect is Mr. Charles Heathcote, and the contractors are Messrs. Wilson, Toft, and Huntley, of Manchester.

A new Baptist chapel was opened in Victoria-road, Deal, on the 4th inst. The builders were Messrs. Cottew and Sons, and the chapel seats 600 persons.

At the quarterly meeting of the Glasgow United Trades Council, held on Wednesday week, it was reported that they had just received an accession of strength by the joining of the Amalgamated Carpenters and Joiners of the Clyde district.

The Hackney board of guardians, at their meeting on the 3rd inst., instructed Messrs. Lee and Smith, of Queen Victoria-street, E.C., to prepare plans for new males' buildings at the workhouse.

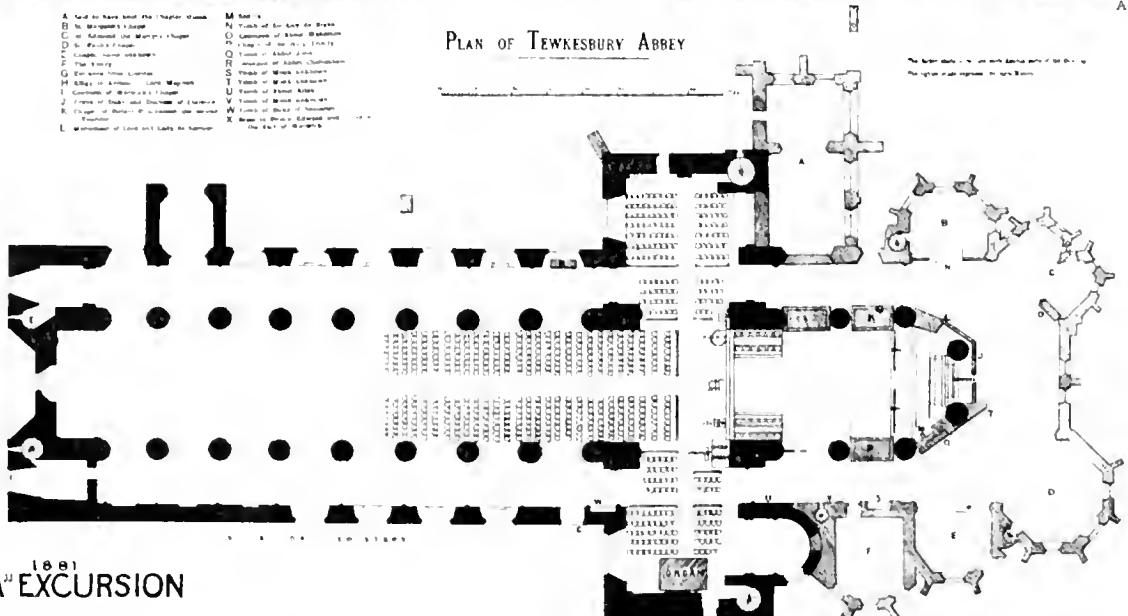

Willison Free Church, Dundee, was reopened on Sunday, after having been renovated and decorated in colours: a work carried out by Mr. William Norwell, of Dundee.

Building Intelligence.

FRODSHAM.—The Church of St. Lawrence, Frods-ham, one of the most interesting ecclesiastical edifices in the north-west district of Cheshire, is now undergoing extensive restoration. The church is partly Norman in character, and, although the actual date of its foundation is unknown, is conjectured to belong to the early part of the 12th century. Additions, in later periods of architecture, have been made to it from time to time, and in the 18th century the whole of the south aisle was restored. The architects are Messrs. Bodley and Garner, of London; and the cost is estimated to amount to between £7,000 and £8,000. The work was begun about twelve months ago, when the building was entirely dismantled. The roofs of the south aisle, nave, and north aisle, and the low galleries and high square pews were entirely removed. The walls of the south aisle have now been partly made good, a string-course and three new windows fixed, and new priests' doorway and buttresses have been constructed. In the nave the old Norman pillars have been cleaned and partly restored. When completed, the church will accommodate about 600 persons. Mr. George Speechly is the clerk of works, and the major portion of the contract has been let to Mr. Richard Becket, of Hartford.

GAMLINGAY.—The parish-church of St. Mary was reopened by the Bishop of Ely on Wednesday week after restoration from the plans of Mr. J. Piers St. Aubyn, of London. The church is a cruciform building in the Early English and Decorated styles, and is built of pebbles, sandstone, and clunch. A new floor, partly tiled and partly boarded, has been laid, and new oaken seats and footboards have been provided in the nave and aisles. The walls have been replastered and all the windows reframed and reglazed, and the two small ones in chancel and a lancet in the north aisle, which were previously blocked up, have been opened out, the aisle-window being filled with stained glass. On the north side a new vestry and organ-chamber have been added. The south porch has been rebuilt, the piscina opened out in south transept. The oak chancel-screen has been restored and surmounted by a cross, new carved brattice-work placed above the choir-stalls, and a window on the south side of chancel filled with stained glass. The exterior of church has been repointed, and the battlements repaired. Mr. John Osborn, of St. Neot's, Hants, was the contractor, and Mr. Luff the clerk of works. The cost has been £2,450 for nave, and £750 for chancel.

GLOUCESTER.—The completion of the restoration of the Old Crypt School, Gloucester, a work which has been going on for the last four months, was completed on Thursday week. The building, which was erected some 350 years ago, is in the Late Perpendicular style. The finest feature in it is the gateway and oriel window over. The lower room, with its dark oak wainscoted walls and ceiling, was long used as the Crypt Grammar-school. The restoration works have been carried out by Mr. Tanner, of Gloucester, from plans prepared by Mr. C. G. Maylard, architect, of London, at a cost of £550.

SHIPBOURNE.—On Saturday last, the new church of St. Giles, Shipbourne, was consecrated. The building, which provides accommodation for 250 people, is in the Early English style of architecture, the plans having been prepared by Messrs. Mann and Saunders, of Great George-street, Westminster. The edifice is cruciform in shape, and a substantial tower rises over the intersection of the chancel, nave, and transepts. The material used is Kentish ragstone, with Bath stone dressings. Among features of the church which deserve notice is the crypt, with its stone-voined roof. It is built under the chancel, and is designed as a family burying-place. The builder was Mr. Allcorn, of Shipbourne, the masonry work having been entrusted to Mr. Hughes, of Maidstone. Messrs. Burke and Co. supplied the marble mosaic pavement, and Mr. Bromfield the carving in wood and stone.

WRELEY.—The parish-church of St. Andrew, Wreley, East Essex, was reopened on Tuesday, after rebuilding, the only portion of the fabric that is left being the tower, which is hereafter

to be heightened. The new church is Perpendicular in style, and consists of nave and north aisle, chancel, with vestry and robing-closet to south, and organ-chamber to north. The exterior of the building is of red brick, with Bath-stone dressings. The aisle and organ-chamber are separated from the church by arcades carried by light octagonal piers with moulded caps and bases. The nave windows and that at east end are of three lights, those to chancel being of two lights. The new pulpit is octagonal and open-pannelled; the choir stalls and nave seats are of stained and polished deal. The floor of nave is laid with wood-paving, and that of chancel with tessellated tiles. The old font has been restored and placed under the tower arch at west end of church. Accommodation has been provided in the church for 300 persons, at a total cost for rebuilding of £3,000. Mr. Edward C. Robins, F.S.A., of the Adelphi, London, was the architect; Mr. John Woodley, of London, the clerk of works; and Messrs. Saunders and Son, of Dedham, were the contractors.

COMPETITIONS.

LIVERPOOL.—The directors of the Lancashire and Yorkshire Railway have awarded the premiums for the designs for the proposed new Exchange Station, Liverpool, as under—viz., 1st, £750, Mr. John West, 4, South-parade, Manchester; 2nd, £500, Mr. H. J. Percival, Old Parsonage, Newchurch, near Manchester; 3rd, £250, Mr. Thos. Mitchell, 17, St. Anne's-square, Manchester.

HALIFAX SLAUGHTER-HOUSES.—At the meeting of the Halifax town council last week a report was received from the Markets Committee stating that they had examined, in committee, competitive designs sent in for the new slaughter-houses, and recommended that a premium of 50 guineas be awarded to the author of the design marked "H.R.H.," and one of 25 guineas to the authors of design under motto "Northern Light." The report was presented: but it seems doubtful whether the premiated plans will be executed, as by a majority of 18 to 17 the committee's further recommendation, that £10,000 be borrowed "for rebuilding and extending the slaughter-houses," was amended to "for re-erecting new slaughter-houses on a site at Ladyship already purchased"; and the minority have decided to memorialise the Local Government Board on the subject. On opening the sealed envelopes it transpired that the first premiated design, "H.R.H.," is by Mr. Edward Hughes, of Huddersfield; and the second, "Northern Light," by Messrs. W. and R. Mawson, of Bradford.

A special meeting of the Commissioners of Sewers for the City of London was held on Thursday week at the Guildhall to receive fresh proposals from the chairman of the Metropolitan and Metropolitan District Railway Companies with reference to the Inner Circle Railway Completion and the proposed street improvements. Sir Edward Watkin and Mr. Forbes were present, and it was explained that correspondence had taken place between those gentlemen as representing the railway companies and the chairman of the City Commissioners, which had resulted in an approximation of terms. After some discussion, it was resolved to increase the contribution from the Commissioners from £250,000 to £300,000 (making, with the Metropolitan Board of Works' contribution, £500,000), on condition that the railway companies make the proposed street improvements, including a new street 60ft. wide. It was also resolved to pay the sum by instalments as the work should be completed. This offer will be laid before the shareholders of the two companies.

The tercentenary memorial statue of Dr. William Harvey, the discoverer of the circulation of the blood, was unveiled at Folkestone, his native town, on Saturday. The statue has been erected on the Lees promenade, and is of bronze on a granite pedestal; it represents Dr. Harvey, in the garb of his own times, holding a heart in his left hand. The head and face are copied from the best portrait of Harvey now extant. The statue is by Mr. Bruce Joy, whose model was selected in a limited competition of three sculptors.

The members of the Wolverhampton Free Library Archaeological Department visited Evesham on Monday week. The Bell Tower, Abbey excavations, and Battlewell were visited, and a paper was read by Mr. Elliott on the Abbey and Battle of Evesham.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

WILTSHIRE ARCHÆOLOGICAL ASSOCIATION.—The annual meeting of the Wiltshire Archaeological and Natural History Association commenced on Tuesday at Bradford-on-Avon. The general meeting, at which about 100 were present, began at the Town Hall at 12 o'clock, when the hon. secretary (the Rev. A. C. Smith) read the report of the association. Sir Charles Hobbhouse then delivered an inaugural address, showing the great uses of archaeology in modern architecture. He said that archaeology was the history of any one of our rural villages, and indeed a miniature history of the whole country. The Rev. Canon Jackson, F.S.A., also made a few remarks, and the Rev. Canon Jones then gave an interesting descriptive account of the town of Bradford. The officers were all re-elected, with Mr. H. E. Medlicott as co-general secretary in the place of Mr. C. H. Talbot, who had resigned from ill-health. The members then separated, and at 3 o'clock reassembled at the parish-church, and visited all the principal objects of interest in the town and immediate vicinity, under the able guidance of Canon Jones. The old Saxon chapel, recently discovered, was an object of especial interest. In the evening the members sat down to a capital dinner at the Swan Hotel, under the presidency of Sir Charles Hobbhouse. Later in the evening, a conversazione was held at the Town-hall, when an interesting paper was read by Mr. Charles Moore, F.G.A., on "Notes on Wiltshire Palæontology," and one by the Rev. Canon Jackson on "The Eminent Ladies of Wiltshire History."

CHIPS.

Emmanuel Church, Putney, belonging to the Countess of Huntingdon Conuexion, was consecrated on Wednesday week. Mr. Loe was the architect, and Mr. W. R. Williams, of Putney, the builder.

Mr. Thornhill Harrison, C.E., one of the inspectors of the Local Government Board, held an inquiry at Goole, on Wednesday week, with reference to an application from the Goole local board for permission to borrow £20,000, for the purpose of taking £2,000 shares in the company recently formed to supply Goole and the district with water. The inspector said he should report favourably on the application.

The Improvement Commissioners of Milton-next-Sittingbourne have received a report from Mr. Henry Robison, C.E., their engineer, stating that the work of laying the water-mains is now practically completed, and that the sewerage works, also carried out under his supervision, will be finished in about six weeks.

At the quarterly meeting of the Salybridge town council, last week, Mr. Councillor Storrs took the opportunity of correcting some statements which had been made at the previous meeting as to the low rate of pay obtained by builders' men and their labourers near Manchester. Mr. Storrs said he had examined his wages-books for a quarter of a century past, and found that the wages of builders' men had considerably increased in that time. In 1856, men working 60 hours per week were paid 2s., a fraction over 4½d. per hour, while to-day they were getting 7d. per hour, which was an advance of exactly 50 per cent. Labourers at that time only got, the best of them, 1s. per week of 60 hours.

The School Board for Leeds have approved plans prepared by Mr. Hepper for new schools to be erected in Dewsbury-road. The schools will be a departure in plan from those already built, being provided with greater class-room accommodation.

The award in the arbitration case between the local board and the gas company at Ashford, Kent, was taken up on Thursday week, when it was found that the local board was ordered to pay the company £10,500 as the purchase-money for their works and undertaking.

At the East Riding petty sessions, held at Hull on Friday week, Mr. Henry Heron, builder, of Hull, was summoned for obstructing the footpath in Dock-avenue, Newington, by building materials placed thereon. It was proved the obstruction had existed, in spite of notices and complaints, for nearly two years, and defendant, who was till recently a member of the Newington local board, the prosecuting authority, was fined 40s. and costs.

Mr. Alexander G. Grubb, assistant master of the Dundee School of Art, has been appointed second master of the Manchester School of Art, at a salary of £250 per annum.

"To a practical man with a taste for mechanics, and the bumps of construction fairly well developed, we can conceive no higher mental treat than a couple of hours spent over the June numbers of that truly marvellous publication *The English Mechanic*. In a hundred and fifty odd pages that make up the bulky mass of letterpress, there is recondite information on almost every conceivable subject, ranging from how to construct a mouse-trap, to the latest method of calculating the phases of Orion.—*The Brightonian*. Price Two-pence of all newsmen, or post free 2½d.—31, Tavistock-street, Covent-garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31, TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is ONE SHILLING for TWENTY WORDS, and Sixpence for every eight words after. All Situation advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in serial advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 6dols. 40c. gold). To France or Belgium, £1 6s. 6d. (or 33f. 30c.). To India (via Brindisi), £1 10s. 10d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

MR. CHARLES WILSON, of 13 and 15, Lidgett-street, New York City, is authorised to receive American subscriptions at the rate of 6 dols. 40c. per annum.

MR. R. M. TUTTLE, of Titusville, Penn., U.S.A., is also authorised to receive subscriptions at the same rate.

Cases for binding the half-yearly volumes, 2s. each.

NOTICE.

Now Ready.

Vol. XL, Price 12s. A few bound volumes of Vol. XXXIX. may still be had, price Twelve Shillings; all the other volumes are out of print. Most of the back numbers of former volumes are, however, to be had. Subscribers requiring any back numbers to complete vol. just ended should order at once, as many of them soon run out of print.

Correspondence.

THE ARCHEOLOGISTS AT ST. ALBAN'S.

To the Editor of the BUILDING NEWS.

SIR,—“The archaeologists wished for admission to the western portion of the nave, but were refused.” The above is a quotation from this week's BUILDING NEWS, referring to a visit of the Royal Archaeological Institute to St. Alban's Abbey; by which it appears that Sir Edmund Beckett, being already a self-constituted master of the restoration, by the fact of his possessing money, which the restoration committee do not, has now proved to be a custodian as despotic as Laud was with the Church in England, and as Wentworth was in Ireland, over two centuries ago.

Sir Edmund Beckett, by not throwing open the nave, or if that was beyond his power, by not exerting all his influence to induce the authorities to do so, has laid himself open to remarks which would certainly not tend to advance his fame and reputation with posterity. It might be said with some appearance of truth, that he was afraid to receive the criticism of a gentleman thoroughly qualified to give it; that he did not come forward to explain his reasons for destroying Abbot Whethamstead's fine work, because he had no arguments sufficiently cogent to combat those of his opponents; that he would not allow a society with unquestionable knowledge of the subject, to even look at his renovating operations, for fear that they would

raise such a storm of adverse criticism that would rouse even the slumbering activity of other Hertfordshire landowners to enthusiasm and liberality for the preservation of the finest relic in their county—nay more, in some respects, in their country. Whatever Sir Edward Beckett's present views may be upon the subject of restorations, I know not; but I hold the opinion that no man by himself should be intrusted with the alteration of any ancient building, unless he has shown by previous existing examples that he has the knowledge and feeling necessary for the attainment of such an object, and has not sullied his fame by any voluntary act, by which he has sacrificed the correct principles of truth in architecture. This latter, I maintain, Sir Edmund Beckett has done, and therefore, in my humble opinion, is disqualified from restoring solely by himself, without the intervention or receiving the advice of any one who is more competent than himself to give it. If Sir Edmund Beckett would only be as liberal in his opinions as he is with his money, we should never have seen an archaeological society turned away from a restoration without being met by the restorer or his deputy, or without even being allowed to view the way in which it is being carried out. Possibly now we shall live to see the doors of the western portals of St. Alban's Abbey grained oak, without being permitted to interfere or prevent such an act, because the author of the deed is in possession of wealth, and, what is more, has proved that he has the will to do it.—I am, &c.

LEWIN SHARP.

31, Cornwall-gardens, Queen's Gate, S.W.
August 8th.

VENTILATION OF SOIL-PIPES.

SIR,—Mr. Buchan's letter (p. 184) shows the angry spirit of one convinced against his will. Sarcasms and irrelevant comparisons are very feeble lines of argument, and are true signs of a weak cause. His figures, in crude criticism of my (avowedly rough) estimations, besides being unfairly valued, omit important items of the specification. I may mention in particular the “chamber” within which the trap is to be built, and which, I confess, I did not myself understand, and, therefore, could not value properly.

Mr. B. asks, “How the bad air generated in the soil-pipe, open only at the top, is to be prevented from accumulating?” in his letter, p. 153, he, in part, himself answers thus: “a 1½ in. ventilating pipe ‘helps to prevent concentration of the sewage-gas at the top of the pipe.’” My answer is, that “bad air” is the product of putrefaction; that putrefaction is a gradual process. That, therefore, “bad air” is primarily produced in minute particles which irresistibly and continuously rise, the same as all other gases lighter than air; that this upward tendency will carry it forcibly through any upward orifice or through any size of crack or pipe; that a downward bend in a pipe will stop progress until accumulation forces the obstruction; that a downward bend fortified by a water-seal, more effectually stops progress; that a pipe orifice at the trap apex of the water-seal is an ever-open gate by which the “bad air” can freely escape, immediately and continuously as it is generated; hence the evident impossibility of any accumulation of “bad air.”

In reply to Mr. Emptage's sensible letter, I must admit that I am “in earnest” in my advocacy of 1½ in. pipes as sufficient vents; nevertheless, I shall be glad to be convinced that a larger pipe is more effective. Granted that Mr. E.'s (once tried) experiment in pouring in a pail of water did virtually unseat the trap, yet the apex of trap being, as I maintain, free from accumulation, there would be little or no harm done. The mere act of pouring would, by concussion and pressure, thrust any small quantity of “bad air” which might be hanging about the water-seal into and through the vent-pipe. The experiment appears to me to be of an impetuous driving, rather than an insidious “sucking,” nature, such as characterises the action of a siphon.—I am, &c.

MICHAEL DREY.

SANITARY PLUMBING AND PLUMBERS' WORK.

SIR,—In reply to Mr. Davies' letter of the 5th inst., that gentleman must be aware that his friend, a manufacturer of the O-trap, in a

printed bill given away to the visitors at the Sanitary Exhibition, calls attention to his patent and asserts that “the advantages of the O-trap have been most fatally controverted in the BUILDING NEWS by Mr. Davies, in reply to some lectures by Mr. Hellyer,” &c., &c. And what I said in my last letter was only a part copy taken from this printed notice, as I stated at the time, and seeing Mr. Davies' name mentioned therein several times, I felt confident that he must be aware of its contents.

Now, where has Mr. D. so fatally dealt with this question? For all that can be said about the whole of Mr. D.'s letters on the above question is that they are only unjust criticism, and have certainly not yet proved that the O-trap is in any respect superior to the S-trap.

Now, was not Mr. Pullen the chief cause of the interruption during the proposed 10 minutes' discussion, by waving a miniature model of a O-trap, and saying that the “O-trap was the only trap that did not require a vent-pipe”? &c., &c.

As to Bramah's people fixing a O-trap under his closet, this, in some respects, appears doubtful; for it appears somewhat singular to fix an O-trap to his w.c. apparatus and a O-trap below it.

In future, your correspondent says he will not “answer any letters signed only with initials, &c., &c.” I am sorry to inform him that at present it would be most inconvenient for me to sign my name in full, and I cannot imagine why he should object to my initials, for it appears to me that, owing to Mr. D. failing to prove that the O-trap is the best, he wishes to dismiss the question now that he himself is criticised, for it is easy to prove that the half S-trap when properly made and fixed in an efficient manner, must of a necessity be one of the best traps out.

I am glad to see Mr. Pullen's improvement on the old square-cornered O-trap, namely, by rounding the bottom and contracting the width of the body. This is a step in the right direction. Then we have another improvement in Mr. Smeeton's “Ellipse”-trap, and Mr. Hellyer's V dip-drap, both of which are much superior to the old square-cornered O-trap with its filth-collecting angles; the use of which I understand Mr. D. to be still advocating in his letters.

Mr. Davies really deserves great praise for the able manner in which he gives us the articles, entitled “Practical Notes on Plumbing,” “Plumbers' Work and Lead Working,” which are, indeed, interesting; but his letters on Sanitary Plumbing and Plumbers' Work, he must own, are a failure.—I am, &c.,

Lambeth, August 9, 1881.

H. B.

SURBITON COTTAGE HOSPITAL COMPETITION.

SIR,—A few days after the appearance of our letter in your issue of the 29th ult., we received our drawings from the committee at a cost of 2s. for carriage.

After waiting a few more days we received a lithographed circular letter, of which the following is a copy:—

Eastfield, Surbiton, August 4, 1881.
DEAR SIRS,—I am requested by the Committee of the Surbiton Cottage Hospital to thank you for the plans which you were so good as to send to me in response to their advertisement, and which I have the pleasure to return as the Committee have been unable to adopt them.—Yours, &c., J. S. LOXLEY, Hon. Sec.

The cool effrontery of the above, in which you will observe no reference is made to the successful man (if any), is perhaps only what might be expected from a “committee.” We would, however, ask whether the time has not arrived when architects should band themselves together, and form a “defence association” insisting that in all competitions, whether large or small, the designs shall be publicly exhibited, a professional arbitrator employed, and rejected designs returned to the authors, carriage paid. We contend that if a committee publicly advertise their wants, the same publicity should be observed in all the subsequent transactions as being the only safeguard against the repetition of treatment as above.—We are, &c.,

E. AND G.

BAD MANNERS AT THE SANITARY EXHIBITION.

SIR,—I paid a visit to the Sanitary Exhibition at Kensington on Monday week, and beg permission to relate my experience.

A friend of mine, a provincial architect, while examining a w.c., accidentally dropped the lid, and, unless done before, chipped a few pieces off the pan. He was then most rudely accosted by the attendant, who demanded 6d., or his name and address. The lad's manner was so extremely insulting that I advised my friend to do neither until he had first given us his name, and thereby enabled us to complain to his employers. He thereupon said he was an apprentice, and we could do him no harm, and followed us with outspoken remarks to one of the barriers. Here my friend gave his card to a policeman; but as it bore the name of the town only, it was objected to, and on my remonstrating at such excessive care, he called a gentleman, who caught hold of me violently by the arm several times, and said that if I interfered he would have me put out of the building. My friend now added "—Chambers" to his card in pencil; but even now the officious individual required a number, and because there was none, my friend had to give an explanation.

The discussion was eventually terminated when I reminded the officious individual that he had rather roughly treated me, when he said that if I repeated the remark he would have me put out of the building. I wish this threat had been carried out. As it is, I have ascertained the name of the person, and hope to have the pleasure of teaching him, through my lawyer, the lesson on his duties and manners he is so badly in want of.

August 4th.

C. E.

CHIPS.

Calverton Church, near Nottingham, was reopened on Friday, after thorough restoration of the nave, carried out at a cost of £1,100. A new open roof of pitch-pine has been erected, the pews replaced by seats of pitch-pine, and new pulpit and tiled passages provided. The windows, which were modern, have been replaced by others on the lines of the original 14th-century structure. Mr. Townsend was the architect, and Mr. Pattinson the contractor.

The Newton-Abbot highway-board on Wednesday week elected as surveyor, Mr. Brown, formerly of the Teign Valley Railway, at a salary of £160 a year. There were 34 candidates for the appointment.

The Whitehaven board of trustees last week inaugurated the new upper reservoir just constructed on Harras Moor. The reservoir is a covered one dug out of the solid rock, the roof being supported by brick arches. It holds 150,000 gallons, and is 530ft. above the sea-level. The work has been carried out under the superintendence of Mr. Pickering, the town surveyor.

At a meeting held at Callington, Cornwall, on Friday week, it was resolved to enlarge the church by a new aisle on the north side. Mr. J. D. Sedding, of Bloomsbury, London, is the architect.

The rural sanitary authority of Bakewell have adopted plans prepared by Messrs. Fowler and Son, of Sheffield, for supplying Tansley with water, at an estimated cost of £650.

A cabman's shelter is about to be erected at Chesterfield, from the designs of Messrs. Rollinson and Son, of that town.

A very useful kind of varnish is made known by Léon Vidal, which is excellent for producing imitation of ground-glass, and will doubtless be found available for other purposes. The formula is: Sandarac, 18 parts; mastic, 4 parts; ether, 200 parts; benzol, 80 to 100 parts.

The town council of Portsmouth considered last week a recommendation from the sanitary committee to rescind a resolution recently passed, by which £500 was offered as premium for the best scheme of drainage for the borough, but after discussion, the proposition to rescind was rejected.

The parish-church of Bolton-le-Sands was reopened after restoration on the 4th inst. The old north aisle and transept have been replaced by a new aisle, 16ft. wide and 15ft. high to wall-plate, and at the eastern end of this a new vestry has been built. The floor of nave has been lowered 18in., and the tower arch opened out, and a new font and oak pulpit erected. The old windows in nave have been replaced by traceried four-light windows, a new doorway and oak porch added, and it is re-seated with open benches of pitch-pine, accommodating 450 persons. The chancel is re-tiled and rearranged, and new oak choir-benches have been fixed. Messrs. Paley and Austin, of Lancaster, were the architects; the mason's work has been done by Mr. Byrnes, the joiner's work by Mr. Hatch, and the slating and plastering by Messrs. Hall and Son, all of Lancaster.

The members of the archaeological section of the Birmingham and Midland Institute have paid a two days' visit to Gloucester. They inspected Avening Church, Beverstone Castle and Church, Malmesbury Abbey, and the church and Roman remains at Cirencester.

Intercommunication.

QUESTIONS.

[6608].—**Examination for District Surveyors under Metropolitan Building Act.**—Will one who has passed the above examination kindly state the kind of questions you are expected to answer, and the best works to read up for the same?—B. G.

[6609].—**Vaulting.**—Will any experienced reader kindly tell me which is the correct way to ink in vaulting, whether by freehand, by centres, or by French curves, or how?—SANDWICH.

[6610].—**Ovens.**—Could any of your readers inform me of a good practical and inexpensive book on bake-ovens more particularly relating to the hot-air system?—G. F. B.

[6611].—**Measuring.**—Will any of your numerous correspondents kindly answer the following query?—In taking measurement of existing buildings, how to obtain inaccessible heights otherwise than by employing algebra?—C. E. M.

[6612].—**Laying Large Concrete Blocks.**—I would feel greatly obliged to any reader for any account or description of the appliances adopted in laying the large 350 ton blocks of concrete in the construction of some harbour works near Dublin a few years ago. The members of the British Association assembled in that city witnessed the operation of laying, I believe, one or more of those large blocks.—J. K.

[6613].—**Setting Pencil Sketches.**—This year I set my sketches with diluted milk and water, having done it before with impunity. I feared nothing, but since they have dried large spots, size of half a crown, have appeared, which are creamy and wet; although the surface looks greasy, yet it has not penetrated the paper yet. Will some reader give the benefit of his advice as to a cure?—TOAD IN A HOLE.

[6614].—**Chalk in Concrete.**—I am desired by my client to utilise some chalk in the composition of concrete for a party-wall (3ft. by 6ft. high), and I should be much assisted by the expression of some competent opinion on the matter. The ingredients proposed are chalk, ballast with sand (as it rises from the pit), and Portland cement. Could some of your experienced readers give me the benefit of their advice and the correct proportions? The wall would have little other than its own weight to carry, and is protected from the weather.—CHALK.

[6615].—**Deadening Sound in and Keeping Cool Temporary Buildings.**—Can any of your readers inform me what is the best means of deadening sound in a temporary building, and also keeping off the heat of the sun?—M. H.

[6616].—**Order for Additions or Deductions.**—Will any of your readers kindly inform me what is the usual form of order for additions to or deductions from a building contract? Is there any small work in which I can find information on that and kindred subjects?—B. H.

[6617].—**Carlisle Cathedral.**—Will someone be kind enough to give me the exact height from the ground to the centre of the dial of the clock on the tower of Carlisle Cathedral? Also, the diameter of the first or inner girth ring of the dial, the size of the hour numbers, and the diameter of the outer girth ring of the dial, and the length of each pointer.—JOE BLAIN, Carlisle.

[6618].—**Painting and Gilding.**—Living at some distance from a town, and desiring to do a little oil-painting, I should be glad if someone will kindly inform me the process and materials necessary to make a good drab paint. Or, perhaps you can name a book which will give me the information I require. I should also be glad to learn how to transfer gold-leaf to tissue-paper in the manner now adopted by painters.—LEXAURUS.

[6619].—**Carpentering.**—I intend making a studio easel, and before starting, should like a few hints as to choosing the mahogany, especially as regards the seasoning. Also, what is the best glue to get, and whether, in melting the glue, any water ought to be poured in with the glue as well as in the pot underneath?—AMATEUR CARPENTER.

[6620].—**Building.**—What thrust, applied at the top edge in the centre of a well-dried brick and mortar wall, is necessary to overturn it? What is the rule applicable to any dimensions?—OWENS.

REPLIES.

[6611].—**Canada.**—Referring to the query relative to the demand for architects in this Dominion, I may say—writing from Kansas City, United States—that I have recently made a holiday tour through Canada, and within the last two months have visited most of its principal cities. At Quebec, I think an English architect would find little demand for his services, for the population is fully as French as is that of St. Heller's, in Jersey. The French element is pretty strong at Montreal also, but proportionately speaking, not quite so much as it is at Quebec. An English assistant would find everything vexatiously different at home. The public buildings in Montreal are, or many of them, particularly fine, and offer scope for numerous architects. West of that the English predominate. Toronto contains some imposing buildings, quite equal to some of the best at home. Of course, I refer entirely to street architecture. Church work throughout the colony is very much behindhand, and, as for mansions, the name almost is unknown. From one end of Canada to the other I did not meet with a single residence that had pretensions to be defined as anything more important than a villa. Montreal and Toronto are the two principal cities, and after these Quebec, then follow Ottawa, Kingston, Hamilton, and London. They may be taken in that rotation. Montreal is about the size of Hull, or St. Sheffield; Toronto may be of Leicester; Quebec is as big as Plymouth; Ottawa, as Peterborough; Kingston, Hamilton, and London each

are about as large as Inverness or Bedford. Quebec is an old town, all the others are new, and in these towns are concentrated the colonial architects. They exist in about the same proportions as they are at home, whilst no Canadian seems very wealthy. I did not see in the whole of Canada a single beggar, or a person that appeared to be poverty-stricken. At the same time, the professions are rather "mixed up." I was talking to a house-painter one day in Toronto, who told me he had been a lawyer for some years, and before that a veterinary surgeon. Outside the cities above-mentioned, an architect would not have the last chance, without, at least, he brought a saw, an axe, a big hammer, a bag of tennypenny nails, and a strong arm with him. Then he would be able to design a rail fence and a "lumber" built barn and farmhouse, and, having made the necessary plans, might turn to and cut the material from the neighbouring wood, and erect the lot himself. No doubt, a pushing man, whether architect or anything else, stands a good chance in Canada, but he should be young and vigorous. Half-played-out folks do not seem to get on in the colonies. They too often lack application, pine for home, and somehow or other fall hopelessly in behind. I honestly admit, however, that I never expected to find such fine streets in Canada as one sees over and over again in its best cities.—HARRY HEMS.

[6613].—**Reservoir.**—Build the walls and bottom of Portland cement concrete and line the interior with Portland cement. Have three chambers, one of say 12ft. by 10ft. by 4ft. deep to be used as a filtering-chamber, and two others of half the size for storage-chambers, one of which can contain water when the other is cleaned out. The water will be let in at top of filtering-chamber, then pass through the filtering material of gravel, sand, and charcoal downwards, the bottom of this to communicate with both storage-chambers, one of which can be shut off when not needed, the two storage chambers should communicate with one another at top, that each might act as an overflow to the other if necessary. Pipes of anti-corrodo iron. For further particulars, read BUILDING NEWS, Nov. 19, 1875, p. 576; Feb. 11, 1881, p. 159; and answers to Nos. 6429 and 6433, in March 25 and April 1, 1881—HUGH McLACHLAN.

[6617].—**A Difficulty.**—"Swan" was not wise when he declined to let the architect see a priced bill of quantities before his tender was accepted. It is well known that when a priced bill of quantities has to be given up on the signing of a contract, it is for the purpose of allowing for extras and deductions, pro rata, on those prices, and a condition to this effect is generally to be found in the contract. Now since it is on extras that many contractors hope to make a profit, and further that extras are as a rule to be found on certain items, whilst other items in the bill are pretty sure not to be exceeded, it would be possible for the contractor to put a high price on the former and a low one on the latter, having ascertained beforehand that matters would be equalised on the total amount of contract; and if the architect may not examine the bill before accepting the tender to ascertain if such be the case, then it follows that the giving up of a priced bill of quantities might at once be laid aside. In many contracts it is often as important to know pro rata the cost of extras as to know the amount of accepted tender. If the contractor has priced his bill fairly, I can see no reason why he should object to the architect seeing his prices.—HUGH McLACHLAN.

[6622].—**Diagrams.**—It is never advisable to have any folds in lecture diagrams, these should always be carried about in rolls. Cartridge paper mounted on union is perhaps the cheapest for the purpose, it can be had up to 35in. wide, and would have to be mounted to order. Whatman's paper can be bought ready mounted, 26, 33, and 52 inches wide, it is more expensive than the last but is much superior for colouring on though it has the objection of overlapping joints, the paper not being like the others continuous. A useful paper divided into inch squares and again subdivided to various scales may be had of Messrs. Bemrose and Sons, Old Bailey, London; it may be had mounted and is continuous and of German manufacture. Messrs. Lettis and Co. I believe manufacture something similar if not as good. The outlines should be drawn with a sable pencil and not with pen, the latter making too fine a line; the pencil or brush should even be boldly used, the line to be from 1-16 to 1-8 of an inch wide, and drawn with dull black Indian ink not thick enough to run. Colours as usual, but boldly laid on and of a deeper colour than for ordinary drawings.—HUGH McLACHLAN.

[6623].—**Damp Wall.**—The simplest and perhaps the best plan for "Librarian" to adopt, is to hack off the plaster at back of book-case during the dry season, replace by a layer of Portland cement about half an inch thick of one of cement to 1 of river or well-washed pit-sand. This when nearly dry might be finished with a coat of fine stuff and treated like the remainder of the plastering, or the cement worked to a smooth face and painted in oils the following year.—HUGH McLACHLAN.

[6624].—**Ventilating Drains and Cesspool.**—Neither plan would properly ventilate the cesspool, since both allow a large accumulation of foul gases to generate and remain between the surface of the deposit in cesspool and its cover. Both plans cut off the access of those gases from the house, but that recommended by the by-laws is superior. A ventilating shaft should certainly be run up the wall of the house above the eaves and roof or dormers where there are any and finished with one of Boyie's air-pump ventilators for soil-pipes, the shaft for a cesspool should be at least 4in. diameter. The position of air-chamber recommended by the surveyor is bad, since being so close to the house it would be possible for the escaping gases to enter by the nearest window, if any is to be found on the same side of wall, still unless very large, little gas would be able to escape without some other opening. The nearer the air-chamber is situated to the cesspool the better. To ventilate the cesspool itself, a shaft of large size should be built over its covering, reaching up from the ground at least seven feet, that the gas might escape above the level of the heads of those passing near. For drain-pipes up to 9in. diameter I consider a 4in. ventilating shaft is sufficient, though a 2in. one is too small for a 6in. drain. A surveyor cannot compel you to do anything at variance to plans of writings passed by the Board, he being only a servant of that body and responsible to them alone. Would "Country Subscri-

ber" oblige by naming the "rural sanitary board" that is so well advanced in sanitary matters?—HUGH Mc LACHLAN.

[6581].—**Timber Building Construction.**—Use a king post trussed roof with six trusses. For walls, braced timber framing six thick, tied together with iron rods. Feather-edged weather boarding will keep out the rain more effectively than vertical boarding, and is more sightly in appearance. It can be laid its way through towards the bottom of the vertical boarding, settle till it dries out, and cause the lower inside edges to rot.—HUGH Mc LACHLAN.

[6582].—**A Local Board Difficulty.**—According to the "Towns Improvement Clauses Act, 1847," the said authorities are acting strictly within their limits and I do not believe your correspondent would succeed in attempting to compel them to act as he would wish. The clauses which I believe justify the authorities read as follows:—"No house or building within the limits of the special Act shall be built upon a lower level than will allow of the drainage of the wash and refuse of such house or building into some sewer belonging to the Commissioners then existing." The same Act also requires notice of any intention to build or rebuild "with a plan showing the level at which the foundations of such house is proposed to be laid," and further, "within fourteen days after receiving such notice the Commissioners may signify their disapproval of the level at which it is proposed to lay the foundation of any such house, and in case of such disapproval may within the said fourteen days fix the level at which the same is to be laid, subject to such right of appeal as is hereinafter mentioned." "The special act" includes "any Act which shall be hereafter passed for the improvement or regulation of any town or district, or of any class of towns or districts defined or comprised therein, and with which this Act shall be incorporated." This information I have taken from Jenkins' and Raymond's "Legal Handbook for Architects." I can see nothing explaining to whom or how appeal can be made. It is better to give way, nor it would be unreasonable to expect the sewers to be altered for one only, and I agree with the authorities that the lowest floor should be drained; it must be washed at times, and if the water used for that purpose were not carried off by a drain, it would soak through the joints and paving, thereby damaging them.—HUGH Mc LACHLAN.

[6584].—**Party Wall.**—The method indicated in the question is the one to be resorted to in that area in which the "Metropolitan Building Act" is in force. Outside this area the law acts in different ways according to the question whether the ownership of the wall is divided or common. In Scotland there may be further variations of which I am ignorant. A very good explanatory reply on the subject appeared in the BUILDING NEWS, "Inter-communication," No. 5414, May 18, 1877.—HUGH Mc LACHLAN.

[6587].—**Plunge-Bath.**—Portland cement concrete is as good a material as any for building the walls and floor of a salt-water plunge-bath. Clay puddling would then be unnecessary. Brickwork in cement with glazed brick or tile lining has a better appearance, the water looking fresher and clearer; it is more expensive and would require puddling. Sections have been illustrated in the BUILDING NEWS—viz., Camden Turkish Baths, Nov. 29, 1878; and Chelsea Swimming Baths, June 29, 1877.—HUGH Mc LACHLAN.

[6588].—**Measuring Paintwork to Windows.**—Since all the books give the method indicated, they show there is such a custom; this, however, applies to the inside only. For the outside, numbering is resorted to, frames and sashes separately, squares at per dozen. It seems rather illogical that two methods should be applied for what is really the same thing. Some number both inside and out, which appears more sensible. "Paint" should, however, remember that the greatest expense in painting is the labour and not the materials, and that many a painter would prefer to cover a much larger surface for the same money to cutting down a few angles and edges. This question has cropped up in "Inter-communication" several times before.—HUGH Mc LACHLAN.

[6589].—**Sashes and Frames.**—I believe there is no standard size, nor can I find mention of it in Loxton or Hurst. Also in discussing a bill with the builder he has not urged it, though he has urged the larger amount of work in proportion to their size, for which allowance should certainly be made. There might well be two prices per foot-super for sashes and frames, say, for those under 15 square ft. and those over that dimension. It is a very difficult matter to price fairly in small work or alterations, and if the builder is reasonable much credit should be given to his word.—HUGH Mc LACHLAN.

[6590].—**Oak and Pitch Pine.**—In the case mentioned by correspondent nothing can beat paint. The grain of oak may be exhibited by rubbing in a mixture of turpentine, oil, and turpentine. I do not think it advisable to use pitch-pine externally. For internal work paint is decidedly ornamental.—HUGH Mc LACHLAN.

[6591].—**Cracks in Concrete Walls.**—These are said to be caused by expansion and contraction resulting from temperature in the case of long low walls. Examples may be seen of concrete walls between Earl's Court and West Kensington, on the District Railway a few years ago. Sometimes they are caused by the lime in the concrete not having been thoroughly slaked before being used. Or as mentioned by correspondent of cracks.—HUGH Mc LACHLAN.

[6592].—**Cistern.**—Deduct all angles and use three iron rods a foot apart, with a depth of two-thirds down, with nut and washer; let two of these be near the sides to strengthen the angles, and the third in the centre of its length. Polished iron cisterns would be better.—HUGH Mc LACHLAN.

[6593].—**Gas Tar Asphalt.**—In answer to the subject by "G. H. G." in question 355 in BUILDING NEWS, June 4, 1875.—HUGH Mc LACHLAN.

[6597].—**London Bridges.**—Most probably in the "Proceedings of the Institute of Civil Engineers," about the dates in which these works were carried out.—HUGH Mc LACHLAN.

[6598].—**Royal Engineers.**—Your correspondent "J. C." does not say whether it is of the officers of Royal Engineers or the ranks that he is anxious to know the duties, advantages, &c., of. I do not think the information would be of any interest to the general class of your readers, but if he will communicate with me direct I will gladly give him any information he requires.—F. W. E., 3, Lawn-terrace, Herbert-road, Plumstead, S.E.

CHIPS

The fine parish-church of North Walsham was reopened on Wednesday week, after the partial restoration of nave, including reconstruction of its roof. Mr. J. Bond Pearce, F.R.I.B.A., of Norwich, was the architect, and the contractors were Messrs. Cornish and Gaymer, of North Walsham. The cost has been about £2,210.

A drinking-fountain is about to be erected at Whitechurch, Salop, at the expense of Mr. Churton, of Rhyl, who has offered the local board £350 towards the cost of removing some old houses opposite the intended site. The design has been prepared by Mr. John Douglas, of Chester.

The Alexandra Hall, at Blackheath, is about to be rebuilt from the plans of Mr. Saville Tucker, and on a fresh site.

The parish-church of St. Mary Magdalen, at South Bersted, near Bognor, was reopened, after restoration, on Wednesday week by the Bishop of Chichester. The dormer windows, high pews, and galleries, have been swept away; a roof of open timber replaces the low plaster ceiling; the windows have been restored in accordance with the date of the edifice (1405); and the internal stonework has been cleansed from whitewash. Mr. Ewan Christian, of Whitehall, was the architect, and Mr. W. Pratt, the builder.

The town council of Hereford, at their quarterly meeting last week, adopted a scheme prepared by Mr. Samuel Harpur, C.E., of Merthyr Tydfil, for a scheme of sewerage on the separate system, the sewage to be utilised on a farm at Litley.

The Eltham local authority have elected Mr. Jeffrey Bennett, for six and a half years assistant surveyor to the local board of Tuahridge Wells, as their surveyor from amongst 29 candidates. The salary is £150 per annum.

The Dublin Artisans' Dwellings Company have this week been handed over by their contractor, the last of a series of houses for the working classes, known as Kirwan-street and Kirwan's-cottages. The largest block consist of 41 separate two-story dwellings, of four rooms each, the rent charged being 1s. 6d. per week. The medium cottages are each planned as a living-room, with kitchen range, two bedrooms, covered scullery, having Varry water laid on, and concreted back-yard, the rent charged being 4s. per week. The third range of cottages consist of 36 dwellings, with two large rooms in each, and these are let at 3s. 6d. per week. The erection of these dwellings is said to have supplied an urgent want in Dublin.

A new pavilion, accommodating 1,500 persons, was opened last week on the South Parade Pier, Southsea. The framework is wood and the roof of iron. Mr. G. Rake is the architect, and Mr. W. Ward, of Southsea, the builder.

The town council of Cheltenham have resolved to call in Mr. J. F. Bateman, C.E., to advise them as to the best means of increasing the water supply.

The foundation-stone of a new Mission Chapel-of-Ease was laid at Leedstown, West Cornwall, on Tuesday week. Mr. J. Piers St. Aubyn, of London, is the architect, Messrs. Carah and Edwards are the builders, and the cost will be about £500.

The Uxbridge Bench of Magistrates on Tuesday directed a bill of indictment to be preferred against Sir Charles Mills for the non-repair of certain roads on his estate at Ruislip, near Uxbridge. The case was brought by the Ruislip parish authorities. The counsel for the defendant argued that there had not been *prima facie* evidence shown that his client was liable. The roads were stated to be in a dangerous state, not having been repaired since 1873.

The parish-church of Llangood, near Beaumaris, which has been rebuilt from the designs of Mr. Kennedy, architect, Bangor, was reopened on Tuesday. Mr. W. Roberts was the contractor.

Foundation-stones of a new Wesleyan chapel at Walsall, Notts, were laid last Wednesday. The designs have been prepared by Mr. Arthur Marshall, architect, Nottingham.

A new organ, by Messrs. Sweetland, of Bristol, is being erected in the church of St. Erth, West Cornwall.

A Caen stone font, with marble columns, has recently been placed in St. George's Church, Newcastle, Staffs. It is the work of Messrs. Jones and Wallis, of Birmingham and London.

PARLIAMENTARY NOTES.

THE PLANE-TREE AT THE SOUTH KENSINGTON MUSEUM.—Mr. M. Henry asked the First Commissioner of Works on Friday last whether there was any intention to cut down the beautiful plane-tree which stands opposite the old entrance to the South Kensington Museum.—Mr. S. Lefevre: There is no such intention that I am aware of; but I have given directions that the tree shall not be subject to any maltreatment. I may observe, however, that if the plans for the extension of South Kensington Museum decided upon in 1876 be carried out, and if a frontage be added to the building erected there, it is difficult to see how the tree can be preserved. But at the rate at which money is being voted for the South Kensington Museum I think the tree will be safe for many years.

ANCIENT MONUMENTS.—Sir J. Lubbock asked the First Lord of the Treasury whether he proposed to take any, and if so, what, steps to provide for the better preservation of ancient monuments, in accordance with the resolution of the House on the 11th of March.—Mr. Gladstone said that any plan submitted to the Government with regard to the preservation of ancient monuments would be carefully considered, but none had been submitted. He must say, however, that he was not in a condition, nor did he know when he would be, to give his hon. friend the satisfaction he desired. But he hoped that some plan would be brought under the notice of the Government to which they might be able to give careful attention.

PROVINCIAL ART AND INDUSTRIAL MUSEUMS.—On Monday Mr. Collings moved as an amendment to the motion that the Speaker leave the chair, a resolution in favour of establishing art and industrial museums in the large provincial towns; and Mr. Slagg, who seconded the motion, advocated a system by which the works of art in our galleries might be reproduced and circulated through the provincial museums.—Mr. Eeroyd supported the motion, not only on account of the benefits it would confer on the industries of the country, but for the civilising and humanising influence it would exercise on the population of the country.—Mr. Cairne, Mr. Wiggins, Mr. Anderson, Mr. Guest, Mr. Storey Maskelyne, and Sir J. Lubbock spoke, and Mr. Mundella, in reply, contended, with regard to South Kensington, for which alone he was responsible, that it existed far more for the provinces than for the metropolis, and recounted in detail the steps taken by the department in the way of grants in aid to local schools, the loan of collections, &c., for the promotion of science and art in the provinces. A division was taken, and the motion was negatived by 85 to 48.

LONDON FIRES.—Mr. Firth on Monday asked the Secretary of State for the Home Department whether his attention had been called to the fact that on July 21 a fire broke out in Ludbrooke-grove-road, Notting-hill, but that no water could be obtained from the water company's main; whether it was the fact that in case of a London fire it was necessary to invoke five separate authorities having no unity of action:—(1) The police, controlled by the Home Secretary; (2) the water companies; (3) the Salvage Corps, controlled by the insurance companies; (4) the Fire Brigade, controlled by the Metropolitan Board of Works; and (5) the streets, controlled by the Vestries; and if he would consider whether those authorities might not be amalgamated for the purpose of fire-extinction.—Sir W. Harcourt had seen a report on the subject, from which it appeared, not that there was a scarcity of water, but that it was not at high pressure, owing to an accident to the main. With reference to the second part of the question, he had to say that the police were not directly concerned in extinguishing fires, having merely to keep order; that the Salvage Corps was employed in the private interests of the insurance companies; while the Vestries were not concerned at all. When the question came to be determined on when the duty of supplying water to the metropolis should devolve, it would certainly become necessary to consider whether the Fire Brigade should not also be placed under the same control as the water service.

The new banking premises of Messrs. Rowd, Green, and Co., in High-street, Colchester, were opened on Thursday week. The building is very lofty, and is Elizabethan in style. The whole of the chief facade, with the exception of the plinth, which is of granite, is of Westwood stone, carved and moulded in the principal features. In the basement are strong-rooms, built in brick and cement, with hoop-iron ties to every course, and over the bank are the manager's rooms, shut off by an 18in. layer of concrete between the girders and an iron door. Mr. Ernest C. Lee, F.R.I.B.A., of Great James-street, Bedford-row, W.C., is the architect, and Messrs. Saunders and Son, of Dedham, have been the builders. The bank was illustrated by a perspective drawing in the BUILDING NEWS for April 11, 1879.

LEGAL INTELLIGENCE.

DISQUALIFICATION OF CONTRACTORS AS MEMBERS OF LOCAL BOARDS.—**FLETCHER v. HUDSON.**—This appeal was heard at Westminster on the 28th of last month, before Lords Justices Bramwell, Brett, and Cotton, when judgment was reserved. The decision of the Court was given on Friday last. The case raised the question whether, if a member did an act—as taking a contract with his board—which was declared to vacate his seat, he was also liable to a penalty imposed on a member acting when disabled from acting. The action was brought against a member of the local board of Grassmere, in Westmoreland, to recover from him a penalty of £50 for acting as member when disabled by such a contract. There were several contracts between the member sued and the Board for work to be done by him in carting materials for roads, the contracts extending from March, 1877, to March, 1878, under which payment was made to him on March 6, 1879, and on that day he sat and voted as a member of the Board. He was sued at the Assizes at Appleby for the penalty, and at the trial the Judge (Mr. Justice Stephen) held him liable.—The defendant appealed from that decision.—Sir J. Holker, Q.C., and Mr. Crompton, for the defendant, the appellant, argued that he was only temporarily “disabled” during the continuance of the contract, and not afterwards, or at the time he sat and voted; that he was not disqualified, though his office was vacated, for he might be reinstated; and therefore was not liable to the penalty, not being “disabled” when he sat and voted, though, as his seat was vacated, he was not a member. The Statute contemplated the case of a member disabled from acting while still remaining a member, whereas here he had ceased to be a member, and was a mere stranger.—Mr. Charles, Q.C., and Mr. Addison, Q.C., for the plaintiff, contended that the action was maintainable, and that there never was a case more clearly within the mischief met by the Act, and that it would be a strange construction of the Act to hold the case was not within it.—Lord Justice Brett was of opinion that the judgment of the Court below must be upheld. He regretted extremely to have to say that the plaintiff was entitled to succeed in an action which he considered ought never to have been brought.—Lord Justice Cotton concurred.—Lord Justice Bramwell, whose judgment was in writing, differed.—If the Statute had said that any member of a board becoming a party to a contract with it should be liable to a penalty and vacate his seat, he could understand it. But he could not see why, if no penalty attached to the entering into a contract except the loss of the seat, there should be a penalty for acting without re-election any more than if the party had never been re-elected. The truth was, it was difficult to apply the principle of the Statute to a trifling case like this. He could not see any reason for implying a penalty applicable to such a case as the present—viz., a case where a non-member acted.—The majority of the Court being in favour of the plaintiff's contention, the appeal was dismissed.

BRIDGE-BUILDING DISPUTE.—At the Cheshire Summer Assizes, on Wednesday week, before Baron Pollock and a special jury, the action of Henry Barber v. Evan Williams and Others was tried. The plaintiff is the clerk of the peace for Carnarvonshire, and brought the action as representing the County against Mr. Evan Williams, contractor, of Bangor city, for damages caused by the fall of a newly-constructed bridge erected by him over the river Ogden at Taly-bont. The bridge in question was one which carried the turnpike from Chester to Holyhead, and in August, 1879, the old bridge was destroyed by floods. Defendants took a contract to erect a bridge in its stead, which had since given way, and the action was to recover damages from them on that account. The evidence was conflicting as to the causes which led to the breaking down of the bridge, and the jury not agreeing, they had to be discharged without coming to a verdict. The case was referred to the official referee, or, unless the parties agree to a verdict before the 2nd of November, to a special referee.

THE BUILDING ACT.—Mr. Charles Lavender, of The Ferns, Wimbledon, was summoned at Worship-street, 3rd August, for expenses incurred under the 47th section of the Building Act. The complainant was Mr. Meeson, district surveyor for East Hackney, North. It appeared that the premises in question were erected or begun by a builder named Parker for a merchant named Middleton. Mr. Meeson surveyed the premises from time to time, but in consequence of irregularities, and their being erected contrary to the demands of the Act, he served notices on the builder to amend them. The work not being done as required, summonses and various processes followed, fines being inflicted for non-compliance. Orders were obtained for the requisite work to be done, and after a certain lapse of time, the work not being done in the interim, the surveyor, in accordance with the Act, put the matter into the hands of a builder to see the works carried out as

required by the Act. Thereby he incurred expenses amounting to £124 4s. 10d.; his own fees, travelling expenses, &c., a further sum of £29 11s. 6d.; and a sum of £5 5s. was charged as solicitor's costs for advising him as to his position under the Act, the total, £159 1s. 4d., being sought to be recovered by these proceedings. The question raised by Mr. Mugliston was whether the right person had been summoned. The complainant proved that Mr. Lavender was trustee of Middleton's Estate under the bankruptcy of the latter, and it was argued that he was therefore the “owner” of the premises within the meaning of the Act. The magistrate (Mr. Barstow) decided that he had no power to make an order on the trustee in bankruptcy, and thought there had been a want of diligence on the part of the surveyor, who might earlier have sued Middleton. A summons previously taken out against the freeholder (Mr. Button) for these expenses had also been dismissed, Mr. Hosick considering he was not owner within the meaning of the Act.

THREATENING BUILDERS.—At Westminster, on Tuesday, John Davis, 64, labourer, of 31, Romney-street, Westminster, was charged before Mr. Partridge with demanding money with menaces from Mr. David Walker, at Johnson-street, Westminster. Mr. Walker, manager to the prosecutors, Messrs. M'Lachlan and Sons, builders, of Johnson-street, Westminster, said that morning the prisoner, who was a stranger to him, came to the office and asked to see one of the firm. He gave no name, and on being asked what his business was, he said he wanted to see Mr. M'Lachlan about the concrete work at the British Museum. It was not “put in” as specified, and unless it was made worth his while it would have to be taken out again. The prisoner also said that it would cost the firm £50 to take it up and alter it. The witness asked him who he was, and whether he had been working on the job. The prisoner said he had not, he was a Government Inspector, and had access to the place, and had been there eight or nine times. The witness asked him what he expected, and the prisoner said, “I will leave that to you; give me something and you shall hear no more about it.” In reply to a question from the witness as to what Governmental Department he represented, the prisoner said he came from Woolwich. In reply to the magistrate the witness said the firm were building a new gallery at the British Museum, and a great part of the site was concreted. The prisoner denied that he made any demand for money. Instead of the builders using concrete at the Museum, they had used old brick-rubbish, and covered it over with a thin layer of concrete. The contract stated that they should put in a layer of 7½ ft. of good concrete, but in some places they had not covered the old bricks and rubbish with more than 4 in. It was a disgraceful piece of work and ought to be looked into. Mr. Partridge remanded the prisoner, consenting to accept bail—one surety in £20.

ALLEGED NEGLIGENCE OF A CONTRACTOR.—At the Warwick Assizes, on Wednesday, before Mr. Justice Watkin Williams, a case was heard in which a Walsall saddler, named Gough, brought an action against Mr. Evans, contractor, to recover £450 compensation for personal injuries, and £86 16s. 6d. damage to goods, by reason of the negligence of the defendant in carrying out his contract. In the early part of last year, defendant was engaged in carrying out certain works on the railway near plaintiff's house, and, for the purpose of excavating the ground, it was necessary to fire charges of dynamite. The charges were fired constantly during the night, and the violent explosions which took place affected Mrs. Gough's health, and she was compelled to leave home, and seek change of air and scene for a month. Plaintiff alleged that by reason of the defendant manufacturing mortar near his house his stock-in-trade was damaged to the extent of £86 odd. Defendant paid £25 into Court, and the jury gave a verdict for £75.

STAINED GLASS.

MAIDSTONE.—The work of restoring the windows in All Saints' Church, damaged by the fatal boiler explosion in the road opposite, on the 3rd December last, has now been completed. The task was carried out by M. J. B. Capronnier, of Brussels, so far as the large east window was concerned, the work of repairing the three other coloured windows which were damaged being intrusted to Messrs. Wailes and Strang, of Newcastle-on-Tyne.

WOLVERHAMPTON.—A meeting of the Henry Rogers Memorial Fund Committee was held on Wednesday week, at the town-hall, Wolverhampton, to select designs for a stained-glass window to be placed in Heath Town Church. Designs and estimates were received from Mr. S. Evans and from Messrs. Camm, Brothers, both of West Smethwick, who had been selected for the final competition. The plans of Mr. Evans were unanimously chosen, and the work has since been put into Mr. Evans' hands.

WATER SUPPLY AND SANITARY MATTERS.

CLACTON-ON-SEA.—Works of water-supply, constructed by a private company, were formally inaugurated at this rising Essex watering-place on Tuesday week. The well is sunk to a depth of 120ft., below which a further boring of 25ft. is made into the chalk, and the water is pronounced by analysis to be of good quality. It is pumped up to, and stored in a tank reservoir, having a capacity of 30,000 gallons, and constructed of wrought iron. This is carried by wrought-iron girders upon a water-tower, which is built of red brick with Bath-stone dressings, and has a flag turret at one angle; the square of the tower is 27ft., and the total height 10½ ft. Mr. Jabez Church, M.Inst.C.E., F.G.S., has been engineer-in-chief, and the work has been carried out under the supervision of Mr. H. Caldicott, C.E. Messrs. Saunders and Sons, of Dedham, Essex, were the builders; Messrs. H. Young and Co., of Pimlico, supplied the machinery, boiler, and all ironwork; and Mr. Tilley, of Walbrook, E.C., excavated the well and boring.

CHIPS.

An adjourned inquest took place at Hull, on Friday, on a woman named Oliver, who was killed on the 4th ult. by the fall of a chimney in Gibson-street. Robert Wilkinson said he was a joiner, and prepared the plans and specifications for building the chimney which caused the accident for Messrs. Thacker, by whom he was employed as “architect.” The foundations were of concrete, but he did not measure them nor see them put in, depending on the contractor's word that they were of more than specified thickness. Alterations were afterwards made by Mr. Thomas Thacker, upon which witness exercised no further control over the work. The contractor, George Sergeant, deposed that he was ordered to remove some of the concrete by Mr. Thacker, and at first declined to do so, but ultimately complied, and he now attributed the fall of the chimney to the alteration. Several witnesses, including an assistant to the borough engineer, having deposed that the workmanship of the chimney and the materials were good, William Thompson, architect, said the chimney fell because it was placed on one corner of concrete, the insufficiency in thickness and bad quality of concrete, and bad arrangement of footings. The jury appended to their verdict of accidental death a rider that it was due to the fall of a chimney through insufficient foundation and the interference of Mr. T. Thacker.

The Chew Magea School Board have appointed Mr. E. Henry Edwards, of Bristol, architect for their new schools.

A new flour-mill has just been completed at St. Austell, East Cornwall, for Mr. Hitchens. It is built of local dressed granite, is five stories high, and covers an area of 70ft. by 40ft. There are eight pairs of stones, driven by Macadam's patent turbine. The building contract has been carried out by Messrs. Harvey and Saunders, and by Mr. Ede, all of St. Austell, and the milling work by Mr. Fisher. The workmen engaged in erecting and fitting the premises were entertained at supper by the proprietor on Thursday week.

A new Board-school at Barnardstown, Newport, Mon., was opened on Monday. It is Gothic in style, and is built of Pennant stone, with brick and Bath dressings, and consists of mixed and infants' departments and teacher's house. Mr. H. A. Goodman, of High-street, Newport, was the architect, and Mr. George Morgan, of Maundee, the builder; the cost of erection has been £2,100.

Berechurch Hall, near Colchester, is being reconstructed from the designs and under the superintendence of Mr. Ernest C. Lee, of London.

Mr. Selim Rothwell, a well-known Manchester artist, died suddenly in a Bolton tramcar on Wednesday night.

At a recent meeting, the life trustees of Sir John Soanes' Museum, 13, Lincoln's Inn-fields, elected as their colleague (in the terms of the Act of Parliament), Mr. George Godwin, F.R.S., F.R.I.B.A., to fill up the vacancy caused by the recent death of their late much-lamented co-trustee, Mr. Frederic Ouvry.

The local board of Torquay have received no fewer than 169 applications for the vacant surveyorship. A committee is at work wading through the voluminous testimonials.

Messrs. Clark, Bennett, and Co., Limited, we understand, have received instructions to fix their patent safety lifts to the Aston Public Library, Birmingham, and the St. Paul's Institute, Burton-on-Trent; they are also fixing their lifts to the National Hospital, Soho-street, and the Paralyzed and Epileptic Hospital, Powis-place, Great Ormond-street, Bloomsbury.

Our Office Table.

THE 36th half-yearly general meeting of the Improved Industrial Dwellings Company (Limited) was held on Friday. The capital expended up to the present time is £729,712. The gross revenue for the half-year has been £32,318, and there is a divisible profit of £12,451. The revenue would have been £1,000 more but for the interest payable on the capital invested in buildings not yet brought into occupation. Losses from empty tenements have been large, but not so large as in the previous half-year—£2,491 against £2,987. The whole charge of the buildings is placed against the revenue. The average death-rate in the buildings has been greatly below the general average.

SOME time since we described the method devised by Mr. A. C. Engert for destroying the echoes too frequently met with in public buildings. We then recorded the successful application of the system to the Chemical Lecture Theatre at the Science Schools, South Kensington. We have just heard of its successful application to the Chapel of Keble College, Oxford, the acoustic properties of which were very bad. In Keble College Chapel steel wires alone are used. The chapel is about 125ft. long, by about 40ft. wide and 60ft. high. It was noted for its loud and strong return-waves, producing an echo of from 6 to 15 seconds' duration. Most satisfactory results have been obtained by the use of Mr. Engert's apparatus. Every word spoken from the pulpit and properly articulated may now be distinctly heard, even when the chapel is empty.

THE Belgian Contractors' Congress, which was originated and organised by the *Chambre Syndicale des Entrepreneurs de Liège*, opened on the 24th ult. Few foreign contractors were present. The programme for discussion was very full, too full: many of the subjects were not touched upon at all. The question which received the greatest amount of consideration was the respective advantages and disadvantages of contracting at a fixed price for the whole work, or on a specified scale of charges. Although no absolute opinion was expressed, it is evident that the general feeling was in favour of tendering a lump-sum. Another point which was discussed was the form in which security should be given by the contractor for the fulfilment of his undertaking. On the Continent it is usual that a cash deposit should be made; and in addition, a certain proportion (sometimes as much as 10 per cent.) is deducted from each payment, as additional security, until the completion of the work. The congress came to the conclusion that personal security should be entirely abolished, that a deposit of 5 per cent. on the total amount of the contract should be made in cash, approved securities, bonds, &c., and 5 per cent. of each payment retained. In connection with the congress an exhibition was held at the Longloz Railway Station. Several English firms were represented, but by far the greater number of exhibits were Belgian.

A MATERIAL, called *carbolineum*, is being largely used in Germany, and to some extent in this country, as a preservative of woodwork, ropes, &c. It is an oil, apparently a petroleum, containing, among other things, about 10 per cent. of carbolic acid and other antiseptic ingredients, and being nearly as liquid as water, is easily applied. It sinks into the wood, and hardens it to some extent, but does not close the pores. It seems to be very effective as a preservative of wood for outdoor use, for wood buried in the ground as posts, or wood constantly wet, or wetted and dried. It is much used on German railways for sleepers, sheds, bridges, and fences, and would be useful to farmers for preserving the woodwork of agricultural implements, among other things.

A JOINT deputation from the Society of Medical Officers of Health and the British Medical Association has been bringing under the notice of the President of the Local Government Board what appears to us to be a very objectionable feature of the conditions on which certain medical officers of health in the provinces hold their appointment. In boroughs where a medical officer's appointment is permanent, the objection does not apply. But there are many districts in the provinces where the appointment is not permanent, and where the person holding the post

has to seek re-election at stated intervals. This gives rise to more than one serious evil. In the first place, the insecurity of the appointment deters many good men from accepting it, especially as it necessitates the surrender of private practice. In the next place, it has a tendency to destroy the independence of the medical officer, who is not likely to render himself disagreeable to persons who may be able to control his re-election. Mr. Dodson, though not wedded to the existing system, is not inclined to make any immediate alteration. He is evidently looking forward to the establishment of county boards as an effective way of dealing with many matters that are now left to the Local Government Board. For the present, therefore, the evils pointed out by the deputation must remain unredressed.

WE have received the following official statement with respect to the National Art Competition, South Kensington.—“The annual exhibition of the works entered for this competition will remain open to the public to the end of September in the Central-hall (first story) of the galleries on the south of the Royal Horticultural Society's Gardens, the entrance to which is on the west side of the Exhibition-road, South Kensington. The free days are Mondays, Tuesdays, and Saturdays. The exhibition this year consists of about 450 works, selected from 190,615 works sent up from 157 schools of art throughout the kingdom, for the annual examination at South Kensington. The subjects of the competition are figure-drawing and modelling, painting in oil and water-colours, and design especially as applied to manufactures. The prizes awarded are 13 gold medals, 52 silver medals, 116 bronze medals, and 179 prizes of books. The Princess of Wales's Scholarships are awarded to the two female students who take the highest prizes of the year in the national competition. Besides these distinctions, which are awarded by the Science and Art Department, prizes are given annually, in connection with the national competition, for specified subjects of design; by the Plasterers' Company for designs for plasterers' work, drawn in monochrome or modelled in plaster. The Owen Jones Memorial prizes are given by the Society of Arts.”

A MEETING was held at the hall of the Society of Arts on Monday night, under the presidency of the Earl of Rosebery, with the object of obtaining increased public support for the Trades' Guild of Learning, and reorganising it on a larger basis. Mr. Blanchard Jerrold suggested that it would be well if a statement of the method of French technical education were made out for the advantage of English working men and women. Professor Warr traced the work of the Guild, which had comprised several series of lectures; and it was now hoped that there would be formed a special Committee for industrial teaching; and that the Trade Unions would co-operate in supplying the machinery for technical education. Mr. T. Burt, M.P., proposed the following Resolution:—“That this meeting approves and pledges itself to support the objects proposed by the Trades' Guild of Learning, viz.: (1) To provide lectures on the history and principles of various industries, with a view to encourage the desire for improved technical education; and (2) to continue the general education which the Guild has carried on for some time by means of lectures and classes.” The resolution was seconded and carried. Another resolution, affirming that the trade societies should be asked to co-operate in organising the proposed lectures and classes, and asking the large employers of skilled labour in London to give the project their support, was agreed to.

ONCE again correspondents of the daily papers are calling attention to the condition of the well-known Water-gate—the work of Inigo Jones, and the only remaining portion of the magnificent abode of Villiers Duke of Buckingham. In contrast to the order and neatness which prevail in all its surroundings, this interesting monument of the past is left to become the receptacle, beneath its arches, for accumulations of rubbish, disgusting and disgraceful, and, besides being locked within a railing, is utterly uncleaned for. Much of the lower portion of the structure, which ought to appear above ground, is half-buried in the adjacent soil. All this must be owing to the fact of its guardianship being under the control of some authority other than that which is exerted

in keeping the adjoining turf, flower-beds, and borders in most exemplary order. Can anyone tell on whom the blame rests?

At the Kidderminster Town Council, on Wednesday, a discussion took place with reference to the recommendation of the Improvement Committee that Mr. E. Guest, the collector, who had lately commenced business as a valuer, should be asked to give up that profession, and that in the event of his declining, notice should be given him. It was contended by some members that Mr. Guest should be allowed to do work beyond that connected with the collection of the rates, and it was pointed out that the town clerk was not compelled to devote the whole of his time to the duties of the office. Ultimately the Council, by ten votes to seven, adopted the committee's recommendation.

IN the course of some quarry operations last year, in the neighbourhood of Beauvais, a large number of ancient-looking sculptures (comprising arms and various objects) were discovered. A committee of local archaeologists was appointed to collect and examine them. This committee did its work with great care, and one of its members lately presented a report to the *Société d'Anthropologie* with drawings and a selection of the finest pieces. There were over 1,000 objects, hatchets, knives, scrapers, arrow-heads, &c., and of unusual beauty. The enthusiasm aroused, however, was not universal, and certain skilled specialists expressed doubts, rousing natural indignation in the honourable archaeologist from Beauvais, who defended his treasure, and asked for a committee of the Society to go to the spot and judge for themselves. M. de Mortillet presided over this committee. Some new objects were discovered, but a better result of the committee's investigations was the finding of the man who had manufactured the whole, and who was by no means “prehistoric!” It was a certain sugar-refiner, Polydore by name, who employed his leisure in fabrication of those arms and utensils, part of which he seems to have put in the way of discovery by archaeologists, and part disposed of commercially!

THE recent experiments made in some of our large towns with the view of improving the quality of gaslight is a step in the right direction. Gas manufacture presents so many phases and separate operations that the struggle to produce the best gas in the most abundant manner, combined with economical working, is a very complicated one. The selection of a suitable coal is one of the most important features of the operation, and on this point we get some useful hints in a pamphlet from the pen of Mr. James Paterson, C.E., of the Warrington Gasworks, which has just been reprinted. The temperature of distillation is also one of the important points. As a general rule, the greater the amount of gas that is driven off, the poorer the quality of the gas will be; and it can be imagined that the struggle between the desire to obtain a good yield by increasing the temperature of the retorts, and the wish to obtain also a gas of good quality, is one that is often fatal to the consumer getting gas of a high illuminating power. Imperfect purification and too high pressure also act in a manner prejudicial to the consumer and to the advantage of the producer. One of the most common sources of bad light is the use of inferior burners, and a little attention and expense in this direction would often succeed in removing considerable and well-grounded complaint.

THE prizes offered by the Worshipful Company of Plasterers, in connection with the Schools of Art of the Science and Art Department, namely £8 8s. for the best, and £5 5s. for the second best, original design in monochrome for one bay of a music-room in a country gentleman's house, have been respectively awarded to George W. Shepherd, of the Coalbrookdale School of Art, and to Alfred Hall, of the Cirencester School of Art; and the prizes for an original design modelled in plaster, for a panel for letting into the wall of the hall of a hunting seat, have been awarded for the best (£7 7s.) to Walter Allan, of the Royal Architectural Museum School of Art, Westminster, and for the second best (£4) to Alfred Rooke, of the Brighton School of Art.

THE latest excavations made by order of the Athens Archaeological Society at Tanagra, the well-known place in Boeotia whence come the charming terra-cotta figures, have, according to

Nature, yielded important results. On the northern side of the town, in front of the principal gate, fifteen tombs were discovered which were completely untouched. They contained some sixty clay figures, most of them perfect, and measuring between 10 and 35 centimetres in height. They represent satyrs and women standing and sitting, and one is a group of two figures. Besides these many vessels were found, amongst which some twenty lekythoi (paint and oil phials) with antique painted ornaments. Unfortunately most of these were broken. One vase which was found in a stone case shows an artistic inscription which designates it as the work of Teisis. Fourteen scraping-irons were found, and in two of the tombs some fifty small terra-cotta ornaments were discovered, most of which were brightly coloured, and some coloured with thin gold. The published report mentions twenty vessels, some broken, ten of which are ornamented with paintings. Two of these are said to be particularly fine. Of the numerous clay figures only eight could be got out in a tolerably perfect condition.

The Earl of Bradford has consented to open the Fine Art Exhibition in aid of the Funds of the new Infirmary at Bolton on the 5th of September next. The infirmary building has recently been erected at a cost of £25,000, and is admirably adapted for the purposes of an exhibition of paintings and works of art. The Exhibition Committee have already been successful in obtaining the loan of a large number of very important and choice works of art from private collections, and it is expected that several eminent artists will respond to the invitation of the Committee and contribute to those already obtained. In addition to the paintings there will be more than forty pieces of sculpture, together with a rich collection of bronzes, art pottery, ancient armour, and other interesting objects, including six cases of specimens of industrial art from the South Kensington Museum. The exhibition will remain open about two months.

On Tuesday in the Public Health Section of the International Medical Congress, an important discussion took place on measures for preventing the spread of the home contagia, such as scarlet fever, smallpox, &c. Dr. Dudfield and Dr. Tripe spoke at some length as to the necessity of a general measure for the notification of infectious diseases. Dr. Thorne Thorne, one of the honorary secretaries, gave instances to show how the spread of scarlet fever was checked in towns having both local Acts rendering compulsory the notification of that disease to the sanitary authority, and hospitals in which the first cases occurring could be isolated. In Leicester, where epidemics have every four or five years caused between 200 and 300 deaths from that disease, the system of notification came into operation in the middle of an epidemic in 1879, and as the result of its operation some 160 cases were soon isolated, hardly a second case taking place in any court or yard from which first cases were removed. Similar and even more striking results were recorded as having occurred at Warrington. From the speeches made and the manner in which they were received it was evident that the opinion of the section was in favour of some compulsory system of registration for cases of infectious disease, but no specific action was taken in the matter.

The *Essex Telegraph* says:—"The BUILDING NEWS of Aug. 5th gives ten sketches of domestic architecture in Essex—gatherings from the sketch-book of F. W. Woodhouse. Essex is particularly rich in these quaint old houses, and it is much to be regretted that some systematic record is not kept of these fast-vanishing beauties. There are many specimens yet remaining of the old half-timbered work of the fifteenth and sixteenth centuries, and the remains of ornamental plastering, some of which are of great beauty of design, and would tax to the utmost the capabilities of our modern workmen. A small remaining portion may yet be seen upon some old houses in Maidenburgh-street, Colchester, which in our boyhood was almost perfect, and there is another splendid specimen at Wivenhoe, of Elizabethan design; also a few others which still exist to protest against the slobbering and rubbishing contract work of our own times." Any of our readers who may find themselves sketching in the neighbourhood may be glad to know of the additional examples mentioned.

The proceedings against the Grand Junction Waterworks Company for neglecting to give a proper supply of water to several firms at the West-end were continued on Wednesday, at the Marlborough-street police-court. One case was concluded, and the Company ordered to pay a fine of ten pounds, and five pounds costs; but a summons taken out by Messrs. Jay, of Regent-street, was only partially gone into, and was then adjourned. Mr. Poland, for the defendants, intimated an intention of appealing to a higher Court, the Magistrate's opinion being strongly against a contention by counsel that the remedy of the complainants, if any, was by action.

On Wednesday a unique exhibition of ancient and modern needlework, shown by the Ladies' Work Society, was opened at Scarborough, supplemented by some valuable and rare specimens of Mediaeval needlework and embroidery. The South Kensington Museum contributed a box or medicine-chest covered with embroidery, said to have belonged to Louis XIII.; a cope in Italian velvet and German embroidery; a chasuble of the 15th century; several coiffrets, and a chasuble of the 13th century; a Spanish orphrey of a cope or chasuble about the date of 1550; and the scarf of a military commander handsomely embroidered to represent arms and musical instruments, in gold and silver lace, with fringe of the same. Turning to the modern works of the fair sex, the great attraction is the quilt exhibited by the Duchess of Connaught. This magnificent work is the result of the labours of the ladies of the Sloane-street Institution, and was presented to the Duke of Connaught on the occasion of his Royal Highness's wedding. Princess Louise is the exhibitor of nine specimens of valuable ancient and modern needlework. Miss Wemyss, of Wemyss Castle, contributes a very handsome screen and hanging. Near it is a curious dress, said to have been worn by Queen Philippa, of Hainault, at a fancy ball. The design is the arms of England and France quartered together in embroidery and appliqué.

THE correspondence with reference to the retention of the organ-screen of Westminster Abbey, to which we referred last week, still continues. Among others, Mr. G. G. Scott writes to express his regret at the recent removal of the transept-screens of the choir, designed by his late father. Mr. Scott adds:—"Until the refitting of the choir by Mr. Blore, the area below the lantern ('the second pavement,' as Dart terms it) was elevated by three steps (forming the *gradus chori*, so frequently referred to in the 'Liber Consuetudinarius') above that of the choir itself. From thence two steps (the *gradus presbyterii*) ascended to the sanctuary. On this 'second pavement' stood the matutinal altar, and here, too, was placed the great Paschal candlestick. Under Mr. Blore, I believe, this area was lowered to the level of the choir, by which change the *gradus chori* was obliterated, and that most awkward flight of five steps, by which the sanctuary is now approached, was the result. May I express a hope that as the organ-screen is, happily, to remain, the ancient levels of the crossing-bay may be restored and its lateral screens re-erected at the higher level? As the pulpit would, of course, be raised with the floor upon which it stands, the change would be a solid gain to preachers and hearers alike."

CHIPS.

A fine art and industrial exhibition and workmen's flower-show has just been held at Bristol. The architect appointed to plan and direct the arrangements of the various buildings was Mr. E. Henry Edwards.

In making excavations in Balkenae-lane, Colchester, for the main sewerage works, the workmen have dug up a Roman altar, having upon it a legible inscription. The altar has been placed in the museum at Colchester Castle.

Mr. R. J. Collier's sale of freehold land on the Alexandra Park estate on Tuesday seems to have been a successful one. The lots sold realised £2,003. The price realised was about £1,300 per acre.

The North Cornwall Railway scheme is so far advanced that last week Messrs. Galbraith and Church, civil engineers, have been instructed by the committee to make preliminary surveys, with the view of determining the route.

Cambridge House, Blackheath, lately destroyed by fire, is being rebuilt from the designs of Mr. J. Wall, A.R.I.B.A., architect, of New Cross: Mr. Banks, of Lewisham, is the builder.

The local board of Long Eaton, near Trent Junction, on Monday raised the salary of Mr. Sheldon, their surveyor, by £20 per annum.

In consequence of sectarian disputes amongst the labourers, a strike occurred on Monday at the new sewerage works now in progress at Ballymena, the contract for which amounts to £10,000.

Llanhydrock House, Bodmin, the seat of Lord Robertes, which was recently destroyed by fire, is to be reconstructed on the old site and old lines, at an estimated cost of £40,000. Mr. Coad, of London, a native of Liskeard, is the architect, and Mr. Lang, of Liskeard, is the builder.

A new Congregational school-chapel was opened at Laisterdyke, near Bradford, Yorks, last week. It consists of assembly hall, accommodating 820 adults, a lecture hall, seated for 140 persons, infants' room for 120, and classrooms. Mr. S. Robinson was the architect, and the cost has been £1,400.

It was reported to the Swansea Harbour Trust, at their annual meeting on Monday, that the new East Docks will probably be ready for opening in October next. Mr. Abernethy is the engineer-in-chief, and Mr. Walker the contractor.

A new passenger-station is in course of erection at New Wincing, near Castle Eden, on the branch line between Thornley Junction and Stockton. Mr. Kitching, of Darlington, is the contractor.

A wrought-iron lectern has just been manufactured by Mr. Henry Chapman, of Colston-street, Bristol. It is to be placed in the new church at the County Lunatic Asylum, and is from the designs of Mr. E. Henry Edwards, architect, of Bristol.

A new reservoir is approaching completion at Cooway, for the local board of that town; it is being constructed from the plans of Mr. James Farrar, C.E., of Bury, Lancashire, under the supervision of the borough surveyor of Conway.

The parish-church of Cwm, in the Vale of Clwyd, was reopened last week after restoration. Mr. R. Lloyd Williams, of Denbigh, was the architect, and the work has been carried out partly by Mr. J. Rhywen Jones, of Rhyl, and since his death by Mr. Walter Williams, of St. Asaph.

MEETINGS FOR THE ENSUING WEEK.

MONDAY.—Discussion on "Plumbing." Mr. Ernest Hart in the chair. Society of Arts room, Adelphi. 7.30 p.m.

Holloway's Ointment.—This ointment may be rubbed into the system, so as to reach any internal complaint. By this means it cures sores or ulcers in the throat, stomach, liver, spine, or other parts. It is an infallible remedy for bad legs, bad breasts, contracted or stiff joints, gout, rheumatism, and all skin diseases.

Trade News.

WAGES MOVEMENT.

THE NAIL TRADE.—The great strike in the Worcestershire and Staffordshire nail trade has come to an end, the men having determined to accept the 20 per cent. advance offered instead of the 30 per cent. demanded.

Doubling Freestone and Ham Hill Stone of best quality. Prices, delivered at any part of the United Kingdom, given on application to

CHARLES TRASK,
Norton-sub-Hamdon, Ilminster, Somerset.
—[ADVT.]

McLACHLAN & SONS, 35, St. James's street, S.W. Builders, Decorators, and House Painters.
Designs and Estimates.

General Repairs and Alterations Executed. Experienced Workmen always in readiness, and sent to any part of the country.—[ADVT.]

BATH STONE.
BOX GROUND,
THE BEST FOR ALL EXTERNAL USE
CORSHAM DOWN
CANNOT BE SURPASSED IN BEAUTY OF APPEARANCE FOR INTERIOR WORK.

TENDERS.

* * Correspondents would in all cases oblige by giving the addresses of the parties tendering—at any rate, of the accepted tender—it adds to the value of the information.

BANSTED, SURREY.—For additions to Banstead School for the managers of the Kensington and Chelsea School District. Messrs. A. and C. Harston, 15, Leadenhall-street, architects:—

Potter, W., Sutton (accepted) ... £3,583 0 0

BARROW-IN-FURNESS.—For the construction of the following streets, for the town council:—Back Cliffe-lane, Hawcut; Blake-street, extending from Hindpool-road to Duke-street; Foundry-street; New-street; Blake-street, extending from Duke-street to Bath-street; Lismore-street; Back-street, between Duke-street and the Volunteer Drill Ground:—

McKenzie, F. (accepted).

BARROW-IN-FURNESS.—For supply of yard gullies, for the town council:—

Messrs. R. Entwistle and Co. (accepted), for 100 of each kind 3s. 3d. each, and 3s. each for any required after the first 100.

BELFAST.—For painting the workhouse:—

Marks, W., Donegal-street, Belfast (accepted) £198 0 0

BEXLEY, KENT.—For the supply of various road materials to the Local Board during the twelve months ending the 23rd September, 1882. Mr. E. Reave Boulter, surveyor. Accepted tenders:—

Gabriel, for broken Guernsey granite, 2in. gauge, 11s. 2d. per ton; ditto Penzance ditto, 11s. 7d. delivered on wharf at Erith; also, for 6 by 12 Pimlico stone kerbing, 10s. 6d. per foot; ditto Kentish ragstone ditto, 10s. 6d.; Kentish ragstone spalls, free from hazzock, 6s. 5d. per ton, delivered free in trucks at Bexley and Sidecup stations.

Manuelle, for broken Quenast granite, 2in. gauge, at 11s. 3d. per ton, delivered at Bexley and Sidecup stations.

Filmer, for broken surface picked field flints, at 8s. 6d. per ton, delivered at Bexley and Sidecup stations.

Tuff, for broken Sittingbourne flint, at 4s. 10d. per yard, delivered free on wharf at Erith.

Benstead and Son, for Kentish ragstone sittings, at 6s. per ton, delivered at Bexley and Sidecup stations.

Allichin, for Dartford flints, delivered on roads of No. 1 District, at 7s. per yard.

BRADFELD, SHEFFIELD.—For widening, raising, and improving Oughtibridge-lane, for the Ecclesfield and Bradfield Highway Board. Mr. F. A. S. Crawshaw, surveyor to the Board:—

White, J., Sheffield ... £570 0 0

Hill, J., Hillsboro' ... 420 0 0

Powell, J., Grenoside ... 395 0 0

Green and Anthony, Totley ... 391 1 0

Fox, J., Bradfield ... 348 0 0

Burrows, H., Barnsley ... 381 7 0

Armitage, B., Walkley ... 312 9 0

Helliwell, J., Deepcar (accepted) ... 296 0 0

BRIGHTON.—For alterations and additions at No. 103, Kings-road, Mr. A. Loader, architect:—

Newnham, J. M., Brighton ... £331 0 0

Lockyer, G. R., Brighton ... 327 0 0

Holloway, Brighton ... 315 0 0

Hackman, W., Brighton (accepted) ... 305 0 0

BRIGHTON.—For alterations and repairs at 81 and 85, Buckingham-road. Mr. A. Loader, architect:—

Lockyer, G. R., Brighton ... £1,188 0 0

Newnham, J. M., Brighton ... 1,177 0 0

* Accepted.

BRIISTOL.—For the erection of baths and washhouses at Jacob's Wells, for the town council. Mr. Josiah Thomas, city surveyor:—

Krauss, August, Bristol (accepted) £13,107 0 0

(Eighteen tenders received.)

For mechanical engineers' work in connection with above baths:—

Fraser, W. J. and Co. (accepted) £3,535 0 0

BROMLEY, MIDDLESEX, AND RATCLIFFE.—For painting the exterior of the Union Workhouse, at Bromley, Middlesex, and the exterior of the workhouse premises at Ratcliffe, for the guardians of the Stepney Union. Messrs. A. and C. Harston, 15, Leadenhall-street, E.C. architects:—

Crisp and Tomlin ... £394 0 0

Shepherd, H. T. ... 324 0 0

Derby, A. W. W. India-road, E. ... 284 0 0

* Accepted.

BROWNHILLS, NEAR WALSALL.—For the proposed sewerage scheme works:—

Law, G., Kidderminster (accepted) £2,377 0 0

BUCKLAND, PORTSMOUTH.—For the erection of new mission-room and class-rooms, Kingston-road, Buckland, for the Rev. E. Jacob, vicar of Portsea. Mr. E. J. Smith, Commercial-road, Landport, architect. Quantities by Mr. W. Yearlye, Clarence-square, Gosport:—

Huyter ... £1,435 0 0

Crow ... 1,416 0 0

Rapley ... 1,400 0 0

Taylor ... 1,303 0 0

Farmier ... 1,300 0 0

Earwaker ... 1,287 0 0

Tull (accepted) ... 1,275 0 0

CANNING TOWN.—For repairs, &c., to South Halkville schools, Canning Town, E. for the West Ham School Board. Mr. J. T. Newman, 2, Pen-court, E.C., architect:—

Crabtree, A. ... £197 12 6

Reed, A. ... 145 0 0

North Bros. (accepted) ... 120 0 0

CANNOCK.—For erection of heating apparatus at West-hill School, for the Cannock School Board:—

Jellyman, Cannock (accepted) ... £82 5 0

CARRIFF.—For supplying and laying concrete at the new free library, for the town council. Messrs. James, Seward, and Thomas, architects:—

Pearson, J. C. (accepted) ... £1,452 4 6

CARLISLE.—For building a byre and repairs to buildings at Walby Farm, Carlisle, for Mr. L. Armstrong:—

Builder's work:—

Routledge, J. and J. ... £105 0 0

Nicholson, J. ... 101 10 0

Tremble and Johnston ... 87 18 6

Irving, J., Carlisle (Kingstown bricks) ... 65 15 0

Ditto (Scotch bricks) ... 60 15 0

Joiner's work:—

Gill, A., Hackenberg ... 32 0 0

Ritson and Parker, Carlisle (red wood) ... 31 0 0

Ditto (white wood) ... 29 0 0

Nicholson, J., Carlisle ... 30 10 0

Gill, H., Carlisle ... 28 10 0

Irving, J., Carlisle ... 28 9 0

Moore, J., Carlisle-by-Carlisle ... 27 18 0

Footbridge, W., Stapleton ... 26 0 0

Roxcroft, G., Hay Close ... 25 10 0

* Accepted.

CARRINGTON, NOTTINGHAM.—For the erection of a villa in Pelham road. Mr. Arthur Marshall, Southey-street, Nottingham, architect:—

Messers, F. ... £2,152 0 0

Vickers, H. ... 1,865 0 0

Bell and Son (accepted) ... 1,788 0 0

CHELSEA, S.W.—For supply and delivery of about 450,000 3in. by 9in. by 6in. yellow deal paving blocks, about 10,250 bushels Portland cement, and about 2,000 yards of Thames ballast, for paying part of Fulham-road, for the Chelsea Vestry. Mr. G. H. Stayton, C.E., surveyor:—

Wood blocks:—

Lee and Chapman, City ... Per 1,000.

Knight, J., Pimlico ... £6 10 0

Lloyd and Co., Nine Elms (accepted) ... 6 7 6

Thames ballast:—

Faller, G. A., Millwall ... Per cub. yd.

Brass, J. H., Chelsea ... 4s. 10d.

Bull, R., Chelsea ... 3 7

Corrington, H., Pimlico (accepted) ... 3 6

Portland cement (scheduled price, 4s. per sack):—

Prass, J. H., Chelsea ... 4 p.c. below.

Weston and Co., Upper Thames-street ... 6

Eastwood and Co., Lambeth ... 7 1

Burrow and Barrow, Queen Victoria-st. ... 12

Mann, A. J., Chelsea ... 12 1

Cleaver and West, Pimlico ... 29

Formby and Co., Grosvenor-road ... 21

* Accepted.

CHICHESTER.—For repair to the workhouse, viz., for stripping and retiling roof, and for a number of small ventilating windows. Mr. J. Kerwood, St. John's-street, Chichester, surveyor:—

Gambling and Sons ... Windows each. Roofs.

Coles ... £1 19 0 £89 0 0

Willsher ... 1 10 0 £5 2 6

Rodgers (accepted) ... 1 2 0 52 10 0

1 6 0 40 10 0

FOREST GATE.—For repairs, &c., to Ollesia-road schools, Forest Gate, E. for the West Ham School Board. Mr. J. T. Newman, 2, Pen-court, E.C., architect:—

North Bros. ... £135 0 0

Abrahams, R. ... 115 0 0

Reed, A. (accepted) ... 96 10 0

HALIFAX.—For the construction and erection of a telegraphic gasholder at Stoney Royd, for the Halifax town council:—

Clayton, Son, and Co. (accepted) ... £9,370 14 9

[Lowest tender but one received.]

HAVERSTOCK HILL.—For erecting Nos. 1, 2, and 3, Wycombe Villas, for Mr. T. D. Bellamy. Mr. R. Groom, architect:—

Toms ... £3,723 0 0

Nash ... 3,575 0 0

Langmead and Way ... 3,458 0 0

Gregory and Bence ... 3,339 0 0

Gould and Brand ... 3,317 0 0

White (accepted) ... 3,279 0 0

HAYES BRIDGE.—For farm buildings at Hayes Bridge Farm, for Mr. John Wild:—

Garratt, G., Uxbridge ... £240 0 0

Hanson, A. and B., Southall ... 203 0 0

Hunt, Hayes ... 195 0 0

Hardy, T., Cowley (accepted) ... 183 0 0

Salter, Hayes ... 183 0 0

HAYLE, CORNWALL.—For painting and renovating the Copperhouse Wesleyan Chapel:—

Hitchens, Redruth ... £91 19 0

Eva, J. K. and Son, Penzance ... 79 10 0

Kinsman, W. H., Penzance ... 65 0 0

Piney, J., Penzance (accepted) ... 57 0 0

HOXTON.—For alterations and additions at the Adam and Eve, Hoxton-street, for Mr. Gilbert. Mr. H. E. Pollard, 14, Duke-street, Adelphi, surveyor:—

Smith, O. G. ... £576 7 0

Marsland ... 307 0 0

Weston ... 280 0 0

Jackson and Todd (accepted) ... 279 0 0

HULL.—Accepted for the under-mentioned street improvements, by the town council:—

Russell-place:—

Wilson Brothers ... £208 4 2

Somerscales-street:—

Hodgson and Harman ... £135 12 0

Hessle-road:—

Pedron, Joseph ... £93 15 1

KINGSTON.—For new roads, sewers, and surface-water drains for the British Land Company, Limited, on their estate at Kingston. Mr. Henry B. Michell, surveyor:—

Keble, Regent's Park ... £1,941 0 0

Dunmore, Hornsey ... 1,814 0 0

THE BUILDING NEWS.

LONDON, FRIDAY, AUGUST 19, 1881.

RECENT EXHIBITIONS AND THEIR RESULTS.

OF sanitary and artistic exhibitions the profession and the public have surely had enough. Now the season has ended, we may venture to inquire what good, if any, they have done? It is not our intention to raise the question whether exhibitions are really of any value to the manufacturer or to the public. All that we need point out is that these displays are not to be looked at as competitions of skill or excellence of workmanship, but rather show the average results of those qualities. Those who send in goods do so with the view of measuring their productions, not so much with others of the same class, but with the level of public opinion. Last week we published the list of awards in the various sections of the late sanitary exhibition at South Kensington, from which we gather that the awards of merit for general excellence are pretty numerous. As the judges are experts in each section, we may at least fairly take the awards as indicating something more than ordinary merit. It will be seen, on glancing down the list of names and the exhibits, that a very large proportion belong to construction, in which the architect and engineer are more or less directly interested. Concrete, stoneware, parquet flooring, paints luminous and non-poisonous, architectural glazed ware, corrugated iron, wall-linings and decorations, non-arsenical wall-papers, window-opening apparatus, sash-lines, door furniture, sill-bars, ventilators of all kinds, heating apparatus and stoves, and all kinds of closet apparatus, valve-closets, and water waste preventers, to say nothing of traps and sanitary ware of every variety, are the leading features; and it is certainly of some service to the architect to know which of these several productions have, after a technical examination of their merits, been most approved.

If it has been the means of bringing before the architect any idea of value in sanitary construction, or if it has served to gauge his own knowledge of sanitary details, the recent exhibition has at any rate served one useful purpose. In the department of planning and hospital construction, very little was shown with which the profession was not already acquainted. Plans and models of sanitary dwellings, hospitals and theatres, artisans' dwellings, and Turkish baths were not wanting; they were contributed by architects and engineers who in many instances had actually carried out the buildings they served to illustrate, and to this extent they were useful as records more or less of value; but we cannot regard them as the best examples of the most recent experience. In the planning and construction of buildings, little improvement, as a matter of fact, has been made of late years. To take ventilation as an instance, the approved principle of admitting fresh air by well-contrived inlets, and of allowing for the escape of the vitiated air by other channels, has not been impugned, and the principles adopted in the construction of prisons and hospitals twenty years ago have been maintained, though some theorists still insist upon the advantage of extracting the vitiated air at the bottom of the room and allowing the fresh air to enter at the ceiling level. Upon this moot point probably architects and engineers will long be divided, however united they may be in approving of a distinct source of supply and a separate means of

egress. The models and plans shown in this section of the exhibition do not help the young and inexperienced architect much in coming to an intelligent decision upon the best means of introducing air, or of extracting it after it has been used. In many of the systems complicated heating arrangements are shown, in connection with various distributing channels for the warmed air, and these illustrations serve more the apparatus-maker than to illustrate the principle of economical warming. We may say the same of the numerous ingenious devices for extracting air or of exhaust cowl, which now claim notice, and the architect must consult his own knowledge and judgment in adapting the most desirable of these appliances to the case he may have in hand. The principle in many of them is the same, though the tyro may easily be led into supposing each pattern he sees to have merits of its own. To take the ordinary suction or air-pump ventilator as an example. Every ventilator which has no mechanical arrangement, such as a rotating-screw or fan, belongs to the principle of an induced current, a principle already familiar to those of our readers who know anything of the effects of currents of air impinging on surfaces in different angles of obliquity. Each claimant in the field has a particular notion of placing the component plates; and some of these are undoubtedly better than others for certain purposes; thus we should prefer the horizontally-disposed plates to prevent a blow-down, but not for currents of air which are generally horizontal.

With regard to hospital planning, the plans we have already described are instructive as tracing the history of this kind of architecture; they all, however, adopt the isolated block or pavilion as the unit, and the isolation of the closets from the ward, and we may usefully compare the first important plan for a hospital—that of the Herbert Hospital, Woolwich—with the plans for the reconstruction of University College Hospital by Dr. G. V. Poore and Mr. A. Waterhouse, A.R.A., both of which we have described. The pavilion system has now been tried, with results which point to it as the only true principle; though physicians and architects will still differ as to the best mode of disposing the blocks with regard to the administrative centre; and probably, from a strictly scientific view, the circular system advocated by Dr. Marshall, which we illustrated lately, is better than the long range with its wasteful length of corridor connection. The plans and designs contributed by Mons. Tollet, Mr. E. C. Robins, F.S.A., Mr. T. Worthington, Professor T. Roger Smith, Mr. H. Saxon Snell, Mr. Ernest Turner, Mr. Yeoville Thomason, Dr. Mouat, Mr. W. Chisholm, Messrs. Coe and Robinson, Mr. F. E. Jones, and Mr. C. O. Ellison indicate the progress made in arrangements and details which we should like to see periodically recorded. Dwellings for the labouring class, if we may judge by the drawings exhibited, show a grasp of conditions, though still leaving a great deal to be desired; but for other kinds of sanitary architecture, such as abattoirs, baths, and wash-houses, there were not enough examples to lead to any satisfactory conclusion with regard to them.

Architects may at least have gathered more practical information with regard to many materials. Nothing can appeal more to one's sense of cleanliness and thoroughness than concrete stable-fittings and paving. Manufacturers seem now to have perfected this material; the same remark applies with almost equal force to stoneware, and no recent exhibition has shown so many illustrations of the value of the material for sanitary and artistic purposes. Here, again, competition is so great that architects will have some difficulty in future in dividing

their favours; the excellence of manufacture is more general. We need only refer to "traps" (the names of which are legion), gullies, drain-pipes, troughs for latrines, and various forms of intercepting arrangements, which are now bewildering from their endless variety. Those which seem to claim the architect's and engineer's attention are comparatively few, and have been pointed out by us. The artistic developments of stoneware and its allied materials, terracotta, glazed ware, faience, &c., have kept pace with their more useful applications, and we have some pleasure in recording a more general taste in matters of design and colour. Scagliola marbles and Parian cements, enamelled bricks and architectural ornament, have supplied the artist with resources which are now more recognised than at any previous time of the present century—that is to say, with artistic sense of what is truthful and honest.

Parquet flooring is a manufacture which has received "first class" mention, and perhaps among modern, or rather revived, manufactures, it holds a deservedly high place. Owing to improved machinery for cutting wood, modern parquetry equals the old French floors. Probably the first parquetry laid in London was in the 17th century. Evelyn notices one room at Cashibury "parquetted with yew." But the manufacture of thin parquet was of later date, and a firm of the name of Steinitz, in 1840, set up a manufactory in London. Improvements in paints have been rapid of late years; and the white zinc paint of the Albissima Company, among others, besides the luminous paint, is worth mentioning. Few of the features of recent exhibitions have been more numerous or important to the architect than fittings. Windows have always been a *crux* to the architect. Praiseworthy attempts have been made to improve upon the common sash-window, but the ordinary sash, with its cords and weights, is still used. Compensating door-hinges, water-tight sill-bars, fasteners of improved form, bell-hanging appliances, bolts and locks, are among the appliances which have been rewarded.

There is one other section to which we may allude, and where we find ingenuity has taxed itself in producing modifications rather than improvements. The "first-class" awards and those of "merit" have been plentifully bestowed in this section. If we carefully examine the closet-apparatus, we find many variations in detail which have not affected the principle in view—that of producing a self-flushing and cleansing arrangement. The points for architects to consider in specifying closet apparatus are the advantage of self-cleansing basins and flushing rims, that of the "valve" over the "pan" closet, and good flushing, and, not least, effective traps and junction with soil-pipe. In the matter of regulating or waste-preventing cisterns, the recent contrivances have tended to perplex rather than make clear, and we may safely say simplicity of action and the avoidance of mechanical valves and other fittings likely to get out of order, are the chief recommendations. The siphon-action and the preventers depending on a vacuum and displacement of air are probably the simplest contrivances. Disconnecting drain-traps and gully-traps possess much likeness, and the opinions of plumbers seem to be divided as to the advantages of the two principal types of traps, and if we are to judge from recent controversies like that reported elsewhere, there is more to be said for the Ω -trap than we were disposed to accord to it. We cannot here advert to stoves: many of general excellence, combining the Arnott and slow-combustion principles with the ventilating-grate, have been placed in the highest class or otherwise commended, and we may await the forthcoming examination of the merits of some

of these in another competition to take place shortly.

PASSAGES AND CORRIDORS.

IT is a frequent characteristic of a badly-planned house that it is full of passages. In nearly all the plans of novices we find long and tortuous passages, often badly lighted, and cutting up the apartments. These first attempts at arrangement invariably place the rooms in a row, each having an external door, with a long corridor or passage leading to them. It is the easiest method of setting about a plan, and this idea is generally that uppermost in the minds of those who have no notion of building, but who like to give their ideas to their architect. More experience leads to a reduction of passages, and the best planner seems to have the art of minimising his passages and locating his rooms round a hall or landing in a compact form. In public buildings where the apartments are numerous and have to occupy wings or other semi-detached blocks, long corridors are of course necessary, yet in planning of this kind it is much easier to design unnecessary passages than just sufficient to give access to the rooms. The whole art of planning economically consists in being able to reduce the length of internal walling, and to dispose the rooms with the least waste of space. The old houses of the 11th and 15th centuries furnish very few examples of wasteful passages, but this is owing to the very different conditions which the old builders worked under. In Haddon Hall, for example, the apartments are ranged round two courts, and they open into one another by doors of intercommunication. Afterwards corridors and galleries became more common, as we find them in the old houses and mansions built in the time of Elizabeth. Lord Bacon, in his "Essay on Building," speaks of "stately galleries" with cupolas in the length of them, in his view of what a perfect palace should be, and we know how important a feature of houses of this age the open gallery was, with its carved balustrades and posts—a feature which still lingers in a few of the old hostleries and inns. These galleries, in one or more tiers, were eminently picturesque means of uniting the several rooms round a court, and they had at least the merit of avoiding an internal and dark corridor. If we refer to the plan of Longleat, a well-known Elizabethan house, we shall find an internal groined corridor round the two courts and lighted from them—a feature not common certainly in English residences, but one borrowed from the Italian cortile, in this instance, by its reputed architect, John of Padua. It is a pity space is too precious in England to allow the use of interior courts, along which outer corridors can be obtained, as we find them at Hampton Court, giving opportunity for painted-glass and other decorations, entirely out of the question in our modern central corridors, where gloom and dust seem to linger. The narrow dingy passage and stairs, and the circuitous corridor, are two essentially modern arrangements, and we find very few modern buildings of ordinary size in which the corridor is made an architectural feature. They usually present monotonous surfaces of dull drab plaster, occasionally relieved with pilasters; they lead often to a blank wall, and are pierced at intervals with dark doorways. A recess or two, a bayed window or a staircase at the end, would make a great difference; but the corridor is now looked upon merely as a necessary evil to give access to a series of rooms which cannot be entered in any other way. The architect treats it as a channel, not much better than a drain, if we may

judge by the miles of dull wasted corridors in many of the blocks of chambers and offices in the City. Dark and dreary, and often unusually tiring and puzzling in their ramifications, they had better have been intersected by more staircases instead of wasted upon a desolate office or two, whose door with ground glass seems to mock the length of the approach.

We may refer, more particularly, to the arrangement of passages and corridors. One of the main principles is to make them communicate in the most direct way. A passage or a corridor ought to connect two points in a manner which shall not suggest any doubt in the mind. For a long corridor to lead to a blank wall and then to turn, and leave the stranger in doubt as to his whereabouts, is one of the worst possible faults, though we are constantly seeing buildings intended for municipal offices and other official purposes, planned with "blind" corridors really leading to no apparent rooms, and only intended to give access to one or two offices in their way. To lead a corridor round a corner to enter perhaps a small office or set of lavatories, is equally objectionable—architecturally speaking, it is *infra dig*; but this sort of arrangement is common also. A corridor from a main hall or centre should lead somewhere, and it is better to make it give direct access to a large apartment or to a hall of some architectural importance than to make it expressly for the purpose of giving access to a few rooms on its route. A circuitous corridor is not only bewildering and tiring, but shows want of contrivance and resource, and generally is the source of other defects. In public buildings corridors may be managed to afford striking effects by making their intersections features, and by producing extent of vista, and some of our leading edifices—the Houses of Legislature, the New Law Courts, and the Manchester Town Hall—furnish instances of admirable arrangements. On the other hand, there are many lamentable failures. Need we notice the spacious, but gloomy and wasteful corridors in the Leeds Town Hall, and many other buildings of recent date? In Classical buildings, arranged on a grand scale, this feature has been and can be made not only useful but impressive, though to accomplish it at the sacrifice of space, and the cutting up and reduction of the apartments, is to increase cost as well as to display poverty of design.

Straightness is very essential to corridors, and any change of direction ought to be shown by a lobby, or some decided indication. With regard to the all-important question of lighting, architects fall into strange blunders and omissions. There are three methods of obtaining light for central corridors: the first is by having courts or areas at intervals, the second by having end lights, and the third by well-holes and floor lights; and there is a fourth mode, which is rather an afterthought than a method, and that is to borrow light through doorways and walls. It is strange how often we see the latter plan resorted to in competition plans as a substitute for design and contrivance. A borrowed light is a mere subterfuge, and cannot be called planning, even if it affords a plea for ventilation, as we sometimes notice it does. The first and second plans we have mentioned are the only architectural means of lighting, and areas should be placed near the junctions and most frequented parts. It is a common fault, too, to find steps in a long corridor, than which a more dangerous expedient could not be devised. If necessary, they are only properly placed at the ends, or near well-lighted lobbies. Resort to gradients is always better avoided, and equally objectionable are narrow corridors and contraction of width. It is better to avoid any break or cause of obstruction, especially in corridors which connect entrances with large rooms and assembly

halls, and to increase the width only near the vestibule. The rules we have given appear self-evident, and yet, strange to say, we have found them so seldom observed in the designs submitted for important buildings, that we think we are justified in calling attention to them. With respect to small buildings and houses, the less we have of passages and corridors the better, as they not only add to cost, but also to discomfort and inconvenience.

THE NATIONAL COMPETITION DRAWINGS AT SOUTH KENSINGTON.—II.

WE now take up the drawings in oil, water-colour, and chalk. The paintings of figures and groups in oil-colours are as usual numerous, and the work this year in the class of oil-studies is full of promise. The gold medals are awarded to students of Edinburgh, Liverpool, and Birmingham. Robert E. Morrison's oil group reflects much honour on the Liverpool South District school. The subject is a stoneware jar or pitcher, and bronze goblet of antique shape, arranged before yellow drapery, or a silken material of golden hue, which is thrown across a partly exposed background or bas-relief. The red geranium in basin brightens up the darker shadows, the light and shade are reflected and half-lights are cleverly put in, and the whole composition is rich and harmonious. For a similar group, Elizabeth Bark, of the same town, receives a silver medal. We must speak very highly of the group by John J. McClymont, of Edinburgh, showing a cracked Chinese vase, with an illuminated book open, relieved by a dark ground; the colouring and reflected light are admirable, and a delicate harmony pervades the work. On the same screen we notice a few groups in oil, for which bronze medals have been given; and of these we must commend the work of Florence Plant, Birmingham, for some vases prettily grouped with wallflowers and a lily. The dark background gives a rich contrast of colour. Equally creditable is Janet McGown's (Edinburgh) group, in which a stoneware jar and fruit have been arranged before a green curtain. The execution is forcible and masterly, and the texture and contrast of colour well painted. A silver medal has been creditably won by Constance Prince, of Manchester Royal Institution, for her excellent rendering of nautilus and other shells and Japanese tray, against a bas-relief background; and Annie Hastling, of the same school, has also earned her reward of a silver medal for her very æsthetic group of a blue-green vase, with plates of pomegranates and peacock feathers. The grouping is natural, a rich harmony of green, yellow, and blues predominates, though these are generally in a secondary key of colour. The execution is massive and bold. An excellent study of drapery has been awarded a bronze medal, the student being Emily Seymour, of Birmingham. The colour is drab, and the treatment of the folds natural. Among the several book-prize oil-studies we must particularly mention as worthy of a higher reward, Lucy Leaver's (Nottingham) admirable group of blue and white vase and plate against a lattice panel. The grey drapery at side, and the shell, are cleverly painted, and a quiet and feeling treatment and tone add to the merit of the work. W. S. Boyd, Birmingham, also takes this prize for some well painted pottery and flowers; C. L. Palmer, South Kensington, for a solidly-painted breastplate and drapery; and F. W. Davis, Birmingham, for a vase and yellow drapery. A group made up of a red earthenware jar, blue vase, and green drapery, has a bronze medal. It is by E. W. Payton, of the same town; and a silver medal distinguishes Samuel May's (W.

London) light Japanese group of a fan, bronze jar, and fruit. Before leaving this class of studies, we may notice a study of a mouldy cheese, pipe, and jug, by W. Keeling, Sheffield, which has a bronze medal.

The monochrome studies in oil from the antique are not so numerous as the groups. James C. Michie, Edinburgh, wins a gold medal for a monochrome study of man with infant in his arms, from a cast, and T. Allison, also of Edinburgh, takes a silver medal for a half-draped female figure of Venus, boldly painted in brown, the figure being set off by a dark background. The horse's head from the antique, by Miss Wight, Kidderminster, is a cleverly-painted study. The subjects in oil from life are few, and, perhaps, it may be argued that our students gain all they require for painting the human figure from casts of the antique. These, however, although they supply almost perfect ideal proportions, do not teach the student so well as the living figure, the mobile forms and muscular development seen in action, nor give him the delicate shades of flesh and half-tints. The highest reward has been won by a Birmingham student, William A. Breakspere, in this class. It is a seated nude figure of a youth, one arm being behind him, painted on a light background. The light and the shaded portions are cleverly managed, and the execution bold and vigorous in handling. A book prize only goes to Anna Ritter, S. Kensington, for a female nude figure, seated, the limbs being well foreshortened, and the flesh-colour and shading executed with considerable skill. Turning to water-colours, the exhibited drawings are equally worthy of the prizes awarded them, though, in an instance or two, the degree of merit has not been very nicely adjudged. Beginning with the groups, Frank Suddards, Bradford, is the winner of the gold medal. The subject is composed of vases, a goblet, Japanese fan, and shells, and the artist has arranged them in a skilful, quiet, unostentatious manner against a dark, warm, sandstone background, carved in low relief, partly made up with drapery. A red flower upon the dark shadowed portion of the latter gives life and colour, and the depth of tone, rich colouring, and forcible execution, leave nothing wanting. It is equal to oil in depth and tone. Joseph W. Stubbs, also of the same town and school, takes the silver medal (as he does in two other cases) for a group of pottery. The bright yellow stone-ware jar lying on its side, and the Chinese figures, are clever and quaintly grotesque in their grouping; and Margaret Moore's (Leicester) delicately-drawn study of white-briar roses in a glass dish is very refined and feelingly coloured. A large water-colour study of a group of game, which receives a silver medal, and several groups, which are distinguished by bronze medals, may be noticed. No kind of subjects are so useful in calling out the skill of the young artist in outline and colour, light and shadow, as a group of objects, in which the fictile element, combined with fruit, feathers, and other *objets de luxe*, are introduced. It is satisfactory to find the works of the schools in oil and water colours chiefly confined to these subjects, and in this respect the exhibition compares favourably with the work sent up by some of the Board Schools, where landscapes and pictures are the staple productions of the scholars. Colouring in monochrome is a strong point in the best schools, and the silver medal drawing of a horse's head, by Julia Mountford, Birmingham, may be taken as a sample of the drawings in this class of study. It is not, to our thinking, quite so good as the drawings for lions' and horses' heads, for which the bronze medal has been bestowed. The horses' heads, from the antique, by T. C. Castle, Birkenhead, and the drawing, by

Katherine Reynolds, Brighton, of the same subject, are both skilful renderings in sepia, from the cast; the first receives a silver and the latter a bronze medal. Robt. C. Daws, of Bradford; Sam. May, West London; Margaret Moore, Leicester; R. Beggs, Edinburgh, are others who have won silver and bronze rewards for water-colour groups. The monochrome ornament from the cast we have briefly noticed, and in this department two lady students carry away bronze medals for excellent work.

The chalk drawings from the antique include many very masterly studies. This time Mary H. Surenne, Edinburgh—a student who has done excellent work before—wins the first prize for a drawing of figure, spirited and feeling, and another female student, Emma L. Osman, South Kensington, takes a second prize. Rowland Holyoake's chalk drawing (accepted at the Royal Academy) is an excellent study from the antique, of man with cymbals, Florence Reason, Bloomsbury, has a well-foreshortened study of limbs, and W. Busk, of S. Kensington, an ancient player, all three receiving silver medals. For chalk drawings from the living model, Alfred Hitchens, S. Kensington, is the highest prizewinner. The figure is that of a man holding a dagger, and there is much muscular movement and expression indicated. A well-drawn figure from life by Constance L. Anson, S. Kensington, wins a silver medal; and the same reward is given to J. W. Stubbs, of Bradford, for a study of boy's head. We notice a clever chalk study from life, of a female figure, by Helen Jackson, of Lambeth; and there are other clever drawings, for which bronze and book prizes are given, that it would be superfluous here to name.

We cannot conclude our notice of the present exhibition without saying a word on a feature of these yearly collections, which reflects one of the most active and growing impulses among the students who attend the Government schools. It is only subordinate to the branches of art we have already been describing. The value of copying good styles of ornament it is needless to urge here, and the work shown of this class is highly commendable. We may instance the studies of enamels. A student of the Training Class, Arthur D. Riley, takes the gold medal, for some beautifully-drawn copies of Italian, Indian, and Japanese enamels. The Della Robbia border of a medallion used externally on the Villa Della Loggia, near Florence, date 1442, is unique. The studies of majolica (awarded), by Dora Lowenthal, are also very interesting, as illustrating the true ware by that name—Spanish and Italian. We note a sgraffito jar and an Azulejo tile among the copies. The studies of arabesque ornament by W. Busk; the design for an inlaid table-top, by M. Hayes, showing some well-disposed Italian ornament; W. G. Schroder's design for fire-dog, and H. Sharpe's drawing of candlestick, are exceptionally good and masterly. The designs for book-cover, by M. Denley, Lambeth; painted ceiling by F. Gibbons, Cirencester, are also creditable evidences of taste in ornament of this kind.

Among the illustrations of wood-carvings we mention here some clever sepia drawings, from Italian and French examples, by A. Whitehead. Natural productions, treated ornamentally, are represented by a few drawings of surface ornament: chiefly by an oak-panel study by T. Finchett, Manchester; leaves and flowers, ornamentally disposed, by G. Randall, Kidderminster; a design for a picture-frame by E. Edgill, Shrewsbury. Studies of historic styles of ornament include copies of architectural mouldings and features. C. P. Chambers, Barrow-in-Furness, has taken the highest prize for a series of sepia drawings from casts exemplifying every period, from

Egyptian to Renaissance Cinque Cento. The Gothic examples are weakly drawn and shaded, and the mouldings and capitals look crude. Though the student earns the prize for industry, we venture to think shaded drawings of this kind of very little use; after all, they are mere fragments snatched from their real position and connection, and leave the student ignorant of the meaning and continuity of the architecture of which they are only disjointed members.

THE WATER QUESTION.—XIV.

EMBANKMENTS.

ON reference to authority we find it was not "a dozen or twenty" reservoirs, as we stated in the last article on this subject, that Mr. Bateman not long since said he was then making, but *ten or twelve*. As if to compensate for this error, however, we did not add, as we now do, that he had made seventy or eighty large reservoirs.

The great embankment of the Vyrnwy reservoir for the supply of Liverpool, the construction of which was begun the other day with so great a ceremony, is the first embankment of the kind—for a large reservoir—in this country. Embankments as high, and higher, have been made with

earth; but this is to be of stone, regularly built as masonry—a huge retaining-wall 84 ft. high. But in general reservoir embankments are made with the materials found on the spot or within a short distance, be they earth, clay, shale, or stone.

Puddled clay, upon which the watertightness of reservoir embankments has for so long a time depended—since, at least, the time of Brindley and canal-making—has come to be regarded with disfavour and distrust where it is itself exposed to the action of water. When some canal-makers complained to Brindley that they could not stop a run of water, his advice was to "puddle it—puddle it!" and the good reputation which puddle has always had in waterworks engineering led at one time to its too free and careless use, and it was solely depended upon for the water-tightness of reservoir embankments, which was not always effected.

Certainly, some reservoir embankments of earth have been made of very great height, and they have stood safely, and there is no apprehension whatever that they will not always continue so, with, of course, due attention to the outer parts, to repair the continued action of the weather—frost, thaw, &c. But these embankments have been well-made, not only in the core, which is formed of puddled clay from end to end of the bank, like a wall, but on each side of it; on the inside to prevent the water in the reservoir having access to it in any considerable body, and on the outside to prevent the water with which the puddle is made being drawn out of it, whether by evaporation or capillary attraction, by which it might become gradually dried, and the cracks which would be consequently formed might extend so far into the wall as to reduce its virtual thickness materially. Rough stone, for instance, or earth loosely tipped in, would admit the air to it, and the water incorporated with the puddle would continue to evaporate as long as the air itself was not saturated with moisture. It does not readily part with the water with which it is incorporated, and not at all if the outer and drier air is wholly excluded from it; but this can only be done by placing against it a compact material. On the other hand, in the presence of water having any motion, it easily dissolves—melts away, and the best puddle for a wall—that is, the closest in texture, melts the soonest under this action; nevertheless, it is absolutely necessary that puddle should be so worked as to bring it to a close texture; but at its best it is porous, and if water has access to it under great pressure, it is only a question of degree how much water will be forced through the puddle wall. In the first place, a great deal of water is used in making it; dry clay will absorb nearly a third of its own weight of water; and if it be taken, not in a purposely hard state, but in a naturally dry state, it will absorb, in the process of puddling, from one eighth to a sixth of its weight of water. Thus, water acting on one face of a puddle wall under pressure tends to force the water out on the other side, as water is incompressible, and the quantity it can force through in a given time is limited only by the smallness of the pores and the length and tortuousness of the course which a run of water must follow. It is, therefore, highly important to protect the puddle from contact with water under great pressure. It might almost seem that if it requires so much protection it can be of little use, and that it might be dispensed with altogether; but this extreme would be as unwise as that of depending solely upon it without precautions; and as it is so readily procurable, it remains still a necessary material for waterworks reservoirs.

There are two kinds of puddle—clay puddle and gravel puddle—proper to be used for different purposes, or rather in different positions, for the same purpose of watertightness, the one consisting of clay only, the other with stones incorporated. When there is a liability to a wash of water, stones are necessary to hold the clay together, and of stone or rounded gravel-stones are the best, besides being generally the more easily obtained, inasmuch as they are more uniformly dispersed through the mass of clay than angular stones can be in the process of working, which is by cutting and cross-cutting with long bladed tools, reaching down at every stroke through the layer of clay being worked into the puddle beneath it. The tool slips out a rounded gravel-stone without much disturbance of the adjoining clay; but angular stones, when struck by the puddling tool, have a tendency to congregate together. Gravel puddle is proper to be used where weights have to be sustained, as for the walls of a service reservoir. Clay puddle can hardly be worked stiff enough to

support the weight, which squeezes the clay outwards and upwards, and there is an inconvenient settlement of the wall; but with gravel puddle the weight can be sustained and watertightness effected also, because with a mixture of gravel the puddle can be worked stiffer.

The sketches 1, 2, and 3, show respectively a longitudinal section, a plan, and a cross-section of an embankment formed of earth, with a puddle-trench and wall. The trench is shown to be cut straight down, so that the bottom is as wide as the top, and the advantage of this over sloping sides is that, in case the ground should not prove watertight at the depth anticipated, the trench may be carried down to any further depth. The trench is filled in with puddled clay up to the surface of the ground, above which, up to and above the top water-level of the reservoir, the puddle is continued as a wall, having a batter on each side of 1 in. to a foot, and finishing 8 ft. thick at the top; 4 ft. is not a sufficient thickness, 6 ft. is sufficient with precautions, but 8 ft. is advisable; if, however, there be the means of placing a nearly water-tight mass of earth next the puddle, as BB on the sketch, the thickness of the top of the puddle may be 6 ft.

The description of the various parts of the work is as follows:—

In the longitudinal section, Fig. 1, the bottom of the puddle-trench is cut into the hill-side as far down as to pass through loose or fissured ground to a water-tight bottom, which is often found nearer the surface on one side of the valley than on the other. That side should be chosen for the discharge-pipe or culvert, but it cannot always be determined before the puddle-trench has been cut.

On the plan, Fig. 2, A B is the original course of the stream; C D, the two ends of the embankment; E F, an open channel, cut near the bottom of the reservoir; F G, the discharge-pipe, laid in the solid ground; some lines laid in a culvert of masonry, itself laid in the solid ground. G H, an open channel; H, the gauge-basin; I, the waste-weir; I K, the byewash.

The discharge-pipe has a valve on its inner end, at F, and it is necessary to erect a tower of some kind, from the top of which it can be worked. Access to the top of the tower is procured by means of a bridge, either from the top of the embankment or from the side of the reservoir, as shown in the sketch. When the puddle-trench is everywhere sunk below the level at which the water is drawn off, the discharge-pipe is taken round the end of the bank, for the sake of being in the solid ground, and a tunnel is then preferable to an open trench, as shown by the dotted line F, M, N, G, shafts being sunk at M and N. It may not be quite justifiable to put the preference of a tunnel on the less disturbance of the ground, for with careful timbering, perhaps less disturbance would occur with an open trench. The open trench can, at least, be closely filled in again, which cannot be said with certainty of the space between the crown of a tunnel and the earth above it. Although tunnels have of late been much advocated instead of culverts, it would certainly be unwise to adopt them in every case. In every case, however, there is a necessity for a tower or valve-well, for a valve cannot be satisfactorily worked with sloping rods, and because it is absolutely necessary to place a valve on the inner end of a discharge-pipe, if any regard at all be had to the safety of the reservoir. Certainly, discharge-pipes have been laid under embankments, which have had no valves on the inner ends, the discharge being controlled at the outer ends, at the foot of the embankment; but considering that a cast-iron pipe, if of large size, may be broken by the external pressure of the earth, and that, whatever the size, it is subject to leakage at the joints, where

it cannot be got at for repair, this method will not bear repetition. A valve, then, being necessary at the inner end of the discharge-pipe, and a tower for access to it, it becomes desirable to draw off the water, not from the bottom of the reservoir, where it is muddy, but as near the top, at all times, as is practicable, and the tower affords facilities for the insertion of a short pipe through the wall at as many different heights as may be desired. Instead of placing the tower or valve-well in the reservoir at or near the foot of the slope of the embankment, it has been sometimes placed almost in the middle of the bank, close to the puddle wall, and the water is conducted to it by a culvert from the foot of the inner slope of the embankment; but this position does not afford the facilities of drawing off the water at different heights that the exposed tower does. When it is preferred to lay a culvert of masonry, or to form a tunnel, instead of laying the discharge-pipe bare in the ground, it becomes a question whether the water should be discharged through the culvert itself or the tunnel itself, or whether a pipe should still be laid up to the valve-tower, through the culvert or tunnel; but there is very good authority for letting the water run through the culvert or tunnel itself. With a good masonry culvert or tunnel of sound bricks or thick stonework, a pipe in addition seems superfluous, where the reservoir is constructed for one discharge only; but if it be so situated that two discharges are required from it, one, for instance, for a town supply, and another for the stream itself, the continuation of the supply-pipe up to the valve-tower, through the culvert or tunnel, is necessary, the discharge to the stream running on the bottom of the culvert or tunnel beneath the supply-pipe, which is supported from side to side so as to leave room beneath it for the stream-discharge. The quantity given to the stream, under these circumstances, is usually required to be open to inspection by turning it over a gauge-weir to a depth agreed upon, the length of the gauge being fixed, by which the quantity being discharged can be ascertained for the satisfaction of millers and others interested in the stream.

The waste-weir and byewash are shown in the sketch on the opposite side to the other works, but, according to circumstances, they may be on either side. They are very important parts of the work, for when the reservoir is full at a time of flood nearly all the water must pass that way, and therefore not only must the length of the waste-weir be sufficient to prevent the flood raising to a dangerous height against the embankment, but the byewash must be so constructed that it will not be torn up by a great body of water rushing down so steep a channel.

In the cross section, Fig. 2, A is the puddle-trench and wall; B B, material selected from that excavated as being the most easily compacted; C C, a rough stone bank necessary for the outer slope, and advisable also for the inner; D D, the rest of the material excavated, except peat. This is a material which, although sometimes abundant on reservoir sites, is very objectionable in an embankment, even in small quantities.

THE SANITARY AND CONSTRUCTIVE SUPERVISION OF DWELLINGS.*

By LEWIS ANGELL, M.Inst.C.E.

THAT "an Englishman's house is his castle" is a fondly-cherished tradition. Be the Castle one of Indolence, Ignorance, Dirt, or Disease, who dare invade it? But a castle means isolation, a separation of neighbours by

* Read before the Association of Municipal and Sanitary Engineers and Surveyors at Birmingham, on July 8. See p. 65 ante.

walls and entrenchments; and so long as the lord thereof and his retainers remain within the keep, their doings do not concern the outer world. But if the garrison sallies forth, committing devastation, are not the attacked justified in invading the castle? "Self-preservation is the first law of nature"; and if sanitary science, unknown to our mediæval ancestors, has taught the modern Englishman that the safety of his own well-ordered castle is dependent upon his neighbour's being also set in order, surely the most radical opponent of paternal government will concede that freedom must be qualified by the moral and physical rights of our neighbour. One of the earliest applications of this principle of compulsory sanitation was in the Vaccination Acts. Legislation also prohibits the exposure of infected persons and clothing. More recently the principle has been extended by local Acts requiring that the various kinds of infectious disease shall be reported to the medical officer of health. The extension of sanitary supervision to dwellings is therefore not only in harmony with established principles and precedents, but is, in fact, a demand which has found expression in the recent establishment of societies in London and Edinburgh for sanitary inspection on co-operative principles. The latest development of the movement is the "London Sanitary Company," an association of eminent sanitarians who propose to combine philanthropic principles (limited) with the business of a big plumber. The company contemplates, as a "moderate estimate," an annual receipt of 10,000 guineas from 10,000 houses, independently of "entrance fees" and the profits from plumbing. The skilled advice of the highest medical and sanitary authorities will be secured, surveys and reports made by "an efficient inspecting staff acting under the direction of the company's engineers." The company will put dwelling-houses in a perfectly sanitary condition, filter water, cleanse cisterns, prevent boiler-explosions—in fact, sanitary repairs of all kinds will be "neatly executed at the shortest notice." A dividend of 20 per cent. is suggested by the prospectus, and $7\frac{1}{2}$ per cent. guaranteed by the plumber whose business has been acquired by the company as a "going concern," and whose services the company have been fortunate enough to secure as "managing director." It is to be regretted that the aspirations of the company should stop short in so great a work. Surely ratepayers should not object if the company would also take over local boards as a "going concern," and guarantee a dividend, however small. A guinea rate per house per annum officially levied by the sanitary authority would very much more than maintain an efficient and responsible staff of sanitary inspectors, who would extend their protection to the poor as well as to the well-to-do subscribing shareholders, whom alone the "Sanitary Company" proposes to benefit. The fact of the existence of such societies, be they due to philanthropy or stock-jobbing, raises a great question:—Is such sanitary supervision necessary? and, if this be granted, by whom should it be conducted? That supervision is necessary will be admitted by all who, like the members of this association, have had any official experience. Thousands, probably hundreds of thousands, of houses are annually put together, we cannot say built, in such manner as to be dangerous to the lives of the occupants. Not only is stability disregarded, but every essential principle of sanitation ignored; the water-pipes, the drain-pipes, the very site frequently a huge dust-bin, form a combination of contaminating influences which lower vitality and endanger life. This result is due as much to ignorance as to carelessness—a concourse of fortuitous evils rather than a conspiracy, although one regrets to have to add, as the result of official experience, that in too many instances it is also the result of the most wilful and wicked cupidity. As a practical illustration I may be allowed to quote my own official experience. For more than fourteen years past I have had the supervision of by far the largest district in the country governed by a local board; all other places of its size, and very many smaller, have municipal corporations. I refer to the district of West Ham, in Essex, which forms part of the "outer ring" of "Greater London." It includes nearly 130,000 inhabitants, having more than doubled during the last ten years. Some 14,000 houses have been put up during my term

of office, and at present they are increasing at the rate of about 2,300 per annum, equivalent to a new street of nearly 200 houses per month. These buildings require supervision. Being "over the border," we have no building fees as in the metropolis, a fact which induces the speculating builders to come over. If only a guinea were charged on each building—only *one* guinea, not the *annual* guinea invited by the "sanitary company"—my board would, independently of the rates, derive an income which would enable them to provide a qualified and responsible supervising staff not only to enforce the proper construction of new buildings, but to discover defects in old ones. The Local Government Board recently issued a series of model bylaws for buildings, involving very much detail; the advantage of their adoption was manifest, but adoption and observance are very different matters. I would have gladly urged their adoption by my Board had I not also felt there was no chance of their general observance over a district of $7\frac{1}{2}$ square miles with the staff I had at my disposal. The matter was so represented to the Local Government Board, and the imposition of building fees urged so as to provide a staff to carry out the bylaws; the reply was a courteous promise of consideration, but hoping, in the meantime, their "model" would be adopted. To this day the Local Government Board has done nothing to assist the officers, neither has my Board adopted the bylaws, for I hold it is bad policy to enact laws which cannot be enforced, which will be observed only by respectable and entirely disregarded by "jerry" builders. The infliction of penalties here and wholesalescape elsewhere is suggestive of official favouritism, and I maintain that we had better be without such minute laws than to bring them and the officers into disrepute and contempt by their habitual infraction. It is not, therefore, out of any want of appreciation or spirit of opposition that West Ham has not adopted the model laws of the Local Government Board. The moment the means are provided to maintain a staff for their observance, their adoption is certain. And here, in passing, I cannot refrain from giving public expression to a feeling present in the minds of every member of this association. As public officers, the Local Government Board impose their obligations upon us, they favour us with their criticisms, but in no single thing do they either consult, assist, or protect us. When an epidemic breaks out, locally or generally, one of the first suggestions made by sanitary authorities and local newspapers in their panic is to institute a house-to-house visitation; but, in fact, it is seldom attempted, and never effectually done, because it means expense, the ordinary staff being as utterly inadequate for such extraordinary efforts as it generally is unequal to ordinary requirements. But, whatever the extent of the staff, the local authority has no power of inspection unless there be knowledge or reasonable suspicion of the existence of a special nuisance. In any case, the power of entry can only be enforced after compliance with certain formalities involving time and trouble; on the other hand, be the householder ever so anxious as to his safety, he cannot, of right, require an official inspection of his premises unless a nuisance is known or suspected to exist. However serious may be an epidemic, sanitary officers have no power to make house-to-house inspections. It does not appear to be unreasonable that local authorities should have the power during epidemics as well as at all reasonable times, on reasonable grounds, to make house-to-house inspections, or that the ratepayers should, at all times, have the right to require such inspection. A short amending clause in the Public Health Act would readily effect all that can be reasonably expected. But to give effect to such power and satisfy the periodical demand, would impose on the local authorities the obligation of employing a sufficient staff of qualified engineering and sanitary officers. At present, at the best, sanitary inspection is not exercised in any sort of systematic manner—houses are built and drains are laid, especially, as has been said, in the suburbs of London, practically without effective supervision; and why? not for want of power, but because of the paucity of the engineering and sanitary staff. The public are not sufficiently educated in the importance of sanitary principles to induce them to consent to the payment of the necessary staff out of rates; but, as already

shown, there is an equitable way by which ratepayers may be relieved of rates and reconciled to the existence of officials—viz., by putting the burden on the right shoulders and imposing fees upon the chief offenders against sanitary laws—those who build houses and drive profit therefrom. Such fees would, of course, go to the local authority, and not, as in London, to the district surveyor. Some years ago local bylaws required a certificate to be given before any new house was occupied, but the clause has been expunged by the Local Government as *ultra vires*. If fees are imposed by legislation, it should also be enacted that an official certificate should be granted on the satisfactory completion of a dwelling-house. Such a certificate would be of real value, inasmuch as no one need then occupy a new house without its production. Sanitation would thus become a real increment of value in house property. Impressed with these views, I have, for years past, urged them, in season and out of season, long before the conception of the new limited sanitary *quasi* philanthropic companies. Some sixteen or seventeen years ago I joined in a memorial to the Home Secretary to enable local authorities to provide by fees for the proper supervision of buildings. A few years later I wrote to Mr. Gladstone on the subject, and he courteously promised to forward my letter to the proper department. For years past I have urged my own board and others to obtain Parliamentary powers to charge fees, and last year such a clause was included in a Bill promoted by the West Ham local board. There was no opposition, local or otherwise; the Local Government Board not only did not object, but officially recorded its opinion that the circumstances of our case were so exceptional as to justify the application. The metropolis has long had such powers; Bristol has for forty years; even the little town of Eastbourne has such powers. With these precedents, and such exceptional reasons, a committee of the House of Commons expressed its willingness to hear our case, and waited for our evidence; but a power greater than Parliament, an *imperium in imperio*, put a veto on our clauses, and ruthlessly struck them out; this omnipotent power, Lord Redesdale, totally ignorant of the place and the circumstances, is governed by the abstract idea that powers outside the Public Health Act should not be given to local authorities, totally disregarding the fact that every session exceptional powers are given to local authorities throughout the country in accordance with their varying necessities. No less than fourteen towns have recently obtained independent and varying local Acts for the report and registration of infectious diseases, such as small-pox, typhus, scarlet-fever, &c. Why, in the name of all that is "abstract," should these fourteen towns be granted such exceptional powers not included in a general Act, applicable to all towns? Why should Eastbourne in 1879 obtain the powers which are refused to West Ham in 1881? Because, replies my Lord Redesdale, "exceptional circumstances" exist at Eastbourne. Eastbourne being a pleasant resting-place from Saturday to Monday, I took the opportunity of investigating the "exceptional circumstances." A large part of the town is owned by the Duke of Devonshire, the very streets are called "Hartington," "Cavendish," and other of the family names. The duke's local agent is a leading member of the Local Board, and, whether or not he will acknowledge the soft impeachment, has the credit of obtaining the recognition of the "exceptional circumstances" applying to the pretty houses of dual Eastbourne and those who dwell therein during "the season." That any circumstance exists, "exceptional" or otherwise, in Eastbourne which has not tenfold force in West Ham is distinctly challenged. In short, the few hundreds of the upper and middle classes who visit the toy-like town of Eastbourne are to be more exceptionally protected in their temporary dwellings than the thousands of toiling factory artisans who are compelled to live all the year round on the Essex marshes. My present object is not to discuss the wrongs of my own district, but to illustrate, by a typical case, the difficulty local authorities have to encounter in an honest and reasonable endeavour to cope with a great evil and promote sanitary well-being. Here is a case in which an efficient supervision of the operations of building societies, speculating builders, and their accessory works requires an addition of some half-dozen inspectors to the

local staff. "Pay them out of rates," say abstract legislators, "it is a municipal obligation"; but we municipal engineers and surveyors know too well the difficulty of obtaining decent payment for our own services to expect a sufficient assistant staff. Large towns like Liverpool, Manchester, Birmingham, or Leeds, may provide the necessary staff ungrudgingly, but it is not so everywhere. And why should such burdens be laid on the rates? Estate owners and builders are working for their own interests, many making large fortunes.* Why, therefore, should they not contribute a fee, small in itself but large in the aggregate, to provide the supervising staff which their pursuit of fortune necessitates? Because, we are told, they are already adding to the rateable value of the town; if so they also receive, in common with others, the full value for their rates; but, as a matter of fact, such increase of buildings does not lessen the general rates, inasmuch as it involves a proportionate increase in the maintenance of roads, sewers, lighting, scavenging, police, &c., not to mention the School-board and poor-rates generally attending on the increase of a population. While abstract legislators, devoid of practical knowledge, are speculating, speculating builders are working: thousands of houses have been put up, and thousands more will follow before there will be any efficient control under a "general" Act. Imperial Parliament has no time for such trivial local matters. Surely there is as much necessity for "Home Rule" in England as in Ireland. Perhaps some of the members of this association will not assent to the full extent of my assertions. It is obviously derogatory alike to our pride and our efficiency as public officers to admit it; but I unhesitatingly assert, as the result of a long and varied private and official experience, that however good our local bylaws, and however anxious and capable our local officers, as a matter of fact there is no large town in Great Britain where, in its true meaning, sanitary supervision is efficient. Having quoted my official experience, I will crave a like indulgence in my private capacity in illustration of the defects of old houses. I have just entered a new residence; the house is not new, but a good, substantial, well-built family dwelling of the last generation. In it there are as many as four cisterns; in that from which the drinking-water is drawn sewer-gas was "laid on" by no less than three "services" or direct connections with the house-drains—viz., two flushing-pipes to water-closets and an untrapped overflow into the drain; each of the three pipes supplied sewer-gas for absorption by the potable water; another cistern had two connections with the drain—a closet-flush and an overflow-pipe; a third cistern was also connected with the house-drain by an untrapped overflow-pipe; but, curiously enough, the fourth cistern, not intended for the supply of drinking-water, was the only one unconnected with the drains. There were also two sinks in communication with the drains. In fact, within the house there were no less than nine drain connections with sinks and cisterns, exclusive of water-closets. All this was altered at considerable trouble and cost, much greater than if correctly done at first. No sewer gas can now enter the house or contaminate the water. The new arrangements were regarded as "fussy," and sarcastically described as "very scientific," and as a further comment upon the sanitary theories thus practically asserted was quoted the fact, which is undoubtedly true, that in the same house the preceding family had for very many years lived very healthy lives. The obvious reply is that, according to all the laws of sanitary science, the inmates of such a house ought to be ill; under such conditions escape must be due either to the "survival of the fittest," that is, the inherent resistance of robust constitutions, or to the protection of a special Providence which cannot be tempted with impunity, for those who know the law and disregard it may expect and deserve "to be beaten with many stripes." Let me quote another case or two. In the civic palace of the Lord Mayor of London, [in. of floating fungi-] scrub was recently found on the surface, and [in. of mud at the bottom of the cisterns, while a bottle of water on his lordship's table contained hundreds of nematoid worms. Nor is the West-

end of London better than the City, for in the cistern of the Athenæum Club, St. James's, was found a large quantity of offensive mud and animal organisms. The discoveries as to the insanitary condition of the Government offices are only too notorious. In poor neighbourhoods and small houses, the water-butts and cisterns, especially in London, are situated in close courts and contiguous to every kind of filth; generally placed over the water-closet, near a sink and dust-bin, untrapped pipes communicate directly from the cistern to the soil-drains. They are frequently uncovered, consequently the water absorbs the impurities of the surrounding atmosphere; they are not cleaned out from one year's end to another, so that they accumulate mud and slimy vegetation. But it is unnecessary to multiply instances, or enlarge on the existence of evils so well-known to us sanitary officers. To a condition of things such as above described, in houses new and old, is undoubtedly due the lassitude, the illness, and the death of thousands whose inherent power of resistance is unequal to the fight. Those who are subject to such influences stand very much in the relation of the unvaccinated to small-pox: they may escape, but the chances are obviously against those who neglect the protection so well known and so easily attainable. I think it has been sufficiently proved that sanitary supervision is needed in our dwellings, and that it is equally obvious the work should be a public and an official one, and not undertaken by amateur or stockjobbing companies whose philanthropy is confined to shareholders. That the work has not been done before is not the fault of us officers; that it can be done, if paid for, is the very argument on which the companies are founded; but that shareholders should be protected and the poor neglected is a proposition too monstrous to be discussed. Sanitary protection is the legal right of all without subscription or "entrance fee" beyond the obligatory general charge of rates. We have seen how means can be provided without increasing the rates by charging the costs on those who can and should provide them. Surely fees are sufficiently recognised in England: from a railway station to a Government office, can any information be obtained or act done without a fee? Why a fee should be imposed on every new house in London, Bristol, and even little Eastbourne with admitted advantage, but no other town should share in such an advantage, is inexplicable, unless it be to leave an opening for a new development of commercial enterprise in the formation of Sanitary Protection Associations (limited). It is true that an Englishman does not like officialism. We know, by experience, that it is in his nature to put himself in a fighting attitude towards officials; but if we must needs have officers, it is better to have the responsible officer of a legally constituted and recognised authority, than irresponsible employés of a limited liability company. It is a disgrace to our legislation that in England, the cradle of sanitary science, there is room for such companies. We read in the *Sanitary Engineer* of New York:—"Chicago has found the results of her system of factory inspection so beneficial that she is now applying it to tenement houses. Six inspectors are now making a critical inspection of the tenements, and will continue it until the 7,000 tenements which, according to the *Chicago Times*, there are in the city, shall have been examined. The *Times* says that the work has now been reduced to a system, and complete records are kept of all work done. These records consist of date, location, ward, district, name of owner or agent, description of building, number of rooms, number of families, with the number of persons in each, sanitary condition of the building, action taken in abating nuisances found, and explanatory remarks. Each inspector is provided with blanks, which he fills out at the close of each day's work. His report describes the condition of the plumbing, drainage, the local sanitary condition, and notes any violations of the city ordinances. In case anything is found about premises which is detrimental to health, a notice is served on the owner or agent, who is required to comply with the ordinances of the city relating to the abatement of nuisances." We also read that in New York and other States household plumbing is placed under official inspection. This is the outcome of more advanced public opinion in America. I have already hinted that the British ratepayer

is not yet sufficiently educated in sanitary principles; he does not yet appreciate the maxim that "Prevention is better than cure," that it is very much cheaper to employ a few inspectors than to pay the rates consequent upon preventable disease and the untimely death of the humble breadwinner. I therefore submit the following propositions:—That a more efficient and extended supervision of the sanitary and constructive details of all dwellings is necessary. That such supervision should be conducted by the responsible officers of the local sanitary authority. That it is just and expedient that fees be imposed on all new buildings, to provide the cost of such supervision. In conclusion, we must hope more from education than officialism. If sanitary science were studied in our schools, and our youth taught to avoid vitiated air as they would false quantities; if elementary hygiene were recognised as equal in importance with simple equations, many a good and useful life would have been saved for the commonwealth. But now, in the selection of a house, more attention is given to a "dado," a "cornice," and "æsthetic" ideas, than to the cistern, sink, or other vital conditions of health. How difficult even is it to obtain compliance with the most simple and obvious sanitary rules in one's own house! For example, whatever may be the radical defects of construction, sewer-gas may at least be neutralised and kept out of the house by always keeping the closet-door shut and the window open; but we almost invariably find the reverse rule to obtain, the window is shut and the door open, especially at night, when the house is almost hermetically sealed, and a current of sewer-gas, induced by the warm air, enters our sleeping-room at a time when our powers of resistance are at their lowest. In large hotels we find at the end of a long corridor of bedrooms a battery of closets with every window shut and every door open, unless some "fussy" people, like ourselves, take the trouble to reverse the arrangement by opening the windows and closing the doors. It is unnecessary to say more. The canon laws of house sanitation are very simple and easy to observe. Builders will say that "doctors differ"; it is not so; there is no differing upon general principles; they are so well known to every member of this Association, that it is unnecessary to state them; but for the advantage of the general public I may be excused for repeating some of the more important of them. There should be no connection between the house and the sewers excepting for sewage; the soil-pipe should not by any chance ventilate itself into the house; all other drains or pipes from cisterns, baths, lavatories, sinks, &c., should discharge into the open air; the drinking-water should have no connection with the closet. These are cardinal rules, the neglect of which may be fatal; but nearly everyone can discover for himself such neglects. There are, of course, other matters more difficult to detect. We have only stated principles and facts, well known to all sanitarians, which have been repeated over and over again. But sanitarians are few and the population is large; the population is also careless, and it is not until an unexpected, cruel, and irreparable death has smitten a family with deep affliction, that conviction is forced upon the survivors, and alas! when too late, they recognise preventable causes and adopt the simple precautions and protections which, at present, are almost exclusively the privilege of the occupants of workhouses and jails.

PRACTICAL NOTES ON PLUMBING.*

X.

By P. J. DAVIES, H.M.A.S.P., &c.

KNUCKLE BENDS (Figs. 54 and 55).

THESE bends are not unfrequently used in small-pipe work, especially for the bosses of cocks, valves, &c. They are likewise very handy for rain-water pipes, when the pipe is required to convey water from a cesspool through a wall into a rain-water or cistern-head, as also for trapless and some other water-closet work, such as Jennings' closet and trap in one piece. They are made as follows:—Fig. 54, shows the method. Most plumbers cut the end as from A to B, others cut it as shown by the dotted

* It was only last week that the Master of the Rolls, in giving judgment in a certain case, said, among other caustic remarks, "We are not to sacrifice the interests of the public to the interests of the speculative builder."

lines A, D, B, and then work the end B over, as best they can (often taking double the time they

ought) in doing it. The proper way is first to strike the outline of the bend on the bench or floor, as at Fig. 55. X is the point to first strike

the throat A from; then, open your compasses to whatever size your bend may be required, and from H, strike the back, H E, C B; take the compasses and divide the back into any number of equal parts, as at H G, F E, C B, Fig. 57. Here you have 5in. set off, from B to H, Fig. 54. Cut the pipe to about the shape shown in the dotted lines, then place the point of the bolt or tommy (Fig. 23) at A, Fig. 54. Work this up from the throat or lip A, Fig. 55; then take the small point P of your dummy, Fig. 38 B, and place it inside the pipe at about E, and with the mallet or small dresser work the point B and the sides F, up to the proper shape. It will come up better if you open the sides F with your turnpin P R, Fig. 50.

I have found the best method of cutting these knuckles is that described in Fig. 56. It is

done for small-pipe work, by first boring a hole A, and with the chipping-knife (a knife having a leather-covered handle, obtainable at any tool-makers, and similar to a backing-knife, excepting that it is stronger) cut the slit J, and round the ends off as at F, then drive the turnpin up and open the side F K; next with the bolt make the throat or lip, as shown at A, Fig. 55. Now with the mallet and dummy, work the end B, and sides F K up, as that shown at Fig. 55.

THE THEORY OF BENDING (Fig. 57).

A few lines respecting the theory of Bending may not be out of place here, Fig. 57 will assist

in the description. Let J K be the size of your pipe to be bent. Draw the right line J K; Divide this pipe into, say, five parts, as shown at 1, 2, 3, 4, 5, on the circle. Next draw the lines J H and K N, square to the line J K; now strike the line H A also square to J H, and anywhere on this line, as at A, strike the throat line, also the back, as at H G, &c.

Draw the parallel lines V 1, W 2, X 3, &c., through the divided part of the circle, and strike the curved line V L W O, &c. Next divide this curve from H to B, into five or as many parts as you choose, as shown at H G F E C B, and also divide one of these as at A d, and draw straight lines from point to point, as at L L, O O, P P, Q Q, R R; next strike the line J K, Fig. 58., and measure off from J 1, in Fig. 57, and set this distance on J 1, Fig. 58, thus measure from 1, 2, Fig. 57, and set this off on Fig. 58, and so on until the whole is marked off. When all is marked off and laid down as from J to G, Fig. 58, continue from G to K, which will be the exact distance round the bend. From d to E, Fig. 57, measure off the distance of the short line, and place this on the line K J, Fig. 58, as at E d and d G; also measure off L e, Fig. 57, and place this on the line L e, Fig. 58, and so on until you have the lot. Now draw the curved line through the distances or points R 1, Q 2, P 3, O 4, L 5, F 6, and this will be a development of one section, H G, Fig. 57.

Now, seeing this, it is quite clear that when the pipe was in a straight line, the back and throat were of equal length and substance, therefore the piece 58 across R 1 was the same as that across E G; this being the fact; when pulling up bends at at Fig. 46, the molecules of lead must be either driven as it were into a heap at R 1 (but less so at Q 2, P 3, &c.), or worked from K towards E, that is, if you are not to strain the back; but if you work away by hammering the back out, you do not require to thicken the throat part.

I must now direct your attention to the "Split made Bends," Fig. 44. In this case you can take away the surplus lead without trouble.

Now turn to Fig. 55. Here we have the back the thickest part—just what is required, for here it is that the friction of the water takes place with vertical soil-pipes.

DAVIES' SIMPLE "SET-OFFS," OR KNUCKLE-JOINT SET-OFFS.

Fig. 59.—The knuckle-bend may be converted

into a simple "set-off" by the method illustrated in diagram 59. In this diagram you are shown that the pipe B enters A, similar to that at E G. After preparing this for a joint, it is finished as at Fig. 60, and makes good sound

work. One thing is certain: this set-off is strongest at the part where strength is most required.

DAVIES' CLEANSING SET-OFF.

This is another simple set-off, made either with a bend or knuckle-joint. This set-off has a cap and screw, H, cleansing the soil-pipe. This requires no further description, and its

working is all that is required at about one-fourth the cost of labour in making ordinary

set-offs. I am pleased to say that these are the first on record.

(To be continued.)

MR. HELLYER'S LECTURES ON PLUMBING—DISCUSSION.

A DISCUSSION, arranged by plumbers, took place on Monday night on the subject of Mr. S. Stevens Hellyer's recent lectures on "The Science and Art of Sanitary Plumbing," delivered under the auspices of the National Health Society. At 7.30 p.m., the hour fixed for commencement, the large hall of the Society of Arts was well filled, the audience consisting almost exclusively of master and operative plumbers. Mr. Ernest Hart, Chairman of the National Health Society, presided, and was supported on the platform by Messrs. S. S. Hellyer, H. H. Collins, Ernest Turner, Rogers-Field, W. Eassie, S. H. Coles, and others. The proceedings, although animated, were very orderly throughout, and the interest was thoroughly maintained during the two and a half hours of discussion.

At the call of the Chairman, Mr. DANIEL EMPLAGE, Dane-hill Sanitary Works, Margate, opened the discussion by reading a paper. As a provincial man, Mr. Emplage said, he cordially agreed with Mr. Hellyer's allusion to country shops, especially with the advice given to young men to come up to London to improve themselves in their trade. At the same time he must point out that in many parts of the provinces a lively interest was taken in sanitary matters. He should have liked to have heard more from Mr. Hellyer on one or two points, including that of trap-waving or siphonage. About two years ago the speaker fixed an improved hopper-basin into a Beard and Dent's T-trap, taking a 2in. air-pipe from top of outlet into the soil-pipe vent, which was carried up full-bore to the top of the house. He happened to be near when the servant emptied a toilet-pail rather carelessly, and then, with equal thoughtlessness, left without flushing the basin, and the result was that the trap became unsealed. About the same time he fixed a similar basin into an unventilated S-trap, connected by a 6in. bend into a drain ventilated at each end by a 3in. shaft: this trap also occasionally lost its seal. He was rather puzzled by these cases, and had since made siphon-action in traps a special study, experimenting with the old S, the east S, the Eclipse, the V, the S and T-siphons, with several shapes made by his own men for the purpose, and also with stoneware traps of various makers. These were fitted for testing, in connection with improved hopper-basins, to drains and soil-pipes arranged in every possible manner. He had also made notes of over fifty arrangements, carried out in Margate, and from the several experiments was led to the following conclusions:—1st, that the S and T-siphons were, when unventilated, very unsafe, because easily untrapped by waving-out, or siphonage; 2nd, that the east S, the Eclipse and the V, held their seals much more tenaciously than the siphons, but were still very liable, under some conditions, to become unsealed by ventilation; 3rd, that the old S-trap was very much more difficult to untrap than any of those previously mentioned, but even this, when without ventilation, was

had spoken against movable cowl, and although he held a patent in a glycerine-movement cowl, he recommended the use, wherever practicable, of fixed cowl. Something had been said about architects' ignorance of sanitary details; there were many architects who were doing much to instruct people in sanitary matters, and some they knew had promoted these lectures to plumbers, but others declined to move, and he had been surprised lately to find some grave defects in drainage and ventilation in plans by one of the first architects of the kingdom. At the same time, it should not be forgotten that there were so-called plumbers who could not make a joint properly, and did not understand the simplest principles of health; but it was to be hoped that the general interest taken in the subjects and the development of the School-board system would reduce the numbers of this class. In conclusion, he urged plumbers to exert themselves to make theirs, as it should be, the leading and most advanced of the building trades.

Mr. J. VANCE said he had to do work for a gentleman who, finding from Mr. Buchan's book that a pan closet would cost £2 12s. and one constructed on better principles £5, ordered the former, and before long had to spend another £3 on ventilating-pipes to remedy the smells. In this case he ventured to tell the architect that he knew the pan-closet would never be satisfactory, when he was told, "You are not paid to know, but to do." He suggested it would be better for all parties if an architect would explain directly to the plumber what he wanted done in a house, instead of issuing orders through the foreman.

Mr. S. D. SCOFFERN spoke at considerable length on protection from bursting of domestic boilers, education, and other foreign subjects, amidst impatient cries of "Question," and was at length called to time by the Chairman.

Mr. H. H. COLLINS, F.R.I.B.A., said some mention had been made of the trapless closet, and having used it in his own house, with a large family, he must say it answered admirably. If placed in proximity to a sewer, it would, no doubt, be objectionable; but properly ventilated it was infinitely superior to other closets. It had no container, no \square -trap, no apparatus to get out of order, and little brass-work to become corroded. There was, certainly, a tendency to accumulate a little filth beneath the pan, but he gave the housemaid some spirits of salt, with directions to cleanse it about once a week, and that kept it quite sweet. There was one objection about this closet to plumbers—he had never had it repaired. He feared architects, as a body, through carelessness, but not through ignorance, had neglected some practical matters in favour of the artistic side of their profession, till there was some danger that specialists would take this engineering and sanitary work from their heads. In criticising their plans and specifications, however, it should be remembered that architects were not always their own masters, any more than was Mr. Hellyer. Mr. Norman Shaw and other leading architects, and such plumbers as Mr. Hellyer, might be able to refuse to carry out work unless their ideas were followed, but the young and struggling architect or plumber couldn't take such high ground. The way in which the crassly-ignorant or obstinate client could best be convinced of his errors, was by the delivery of such lectures as those of Mr. Hellyer, and the wide-spread discussion they gave rise to. When the public was fully educated, pan-closets and similar abominations would pass into limbo, and be only known as matters of history. He had regretted to hear a speaker early that evening say, in very ill taste, that from all the lectures delivered by Mr. Hellyer he had not gained one particle of information. He was very sorry for that individual. (Loud applause.) He scorned to bestow that false praise which was but satire in disguise; but he must say that the efforts of a gentleman closely engaged in business who had given up so much of his time gratuitously to instruct others in the details of his and their trade, and to impart the benefit of his experience, deserved grateful recognition at the hands of plumbers. (Loud applause.) If Dr. Johnson's dictum were true, that we could learn something even from a fool, the gentleman who had complained of Mr. Hellyer's rudimentary instruction could not be said to have displayed a large amount either of wisdom, intuition, or experience.

Mr. LAMMAS having spoken, Mr. WISE proposed that a plumbers' association should be formed for mutual improvement and protection, the reading and discussion of essays, and of trade questions.

Mr. SAVORY suggested that the whole of Mr. Hellyer's lectures should be printed in book-form, together with the criticisms in the papers and of that evening, and sold at a low price, say, 4d. or 6d. per copy.

The CHAIRMAN said, before calling upon Mr. Hellyer to reply upon the discussion, he ought to explain that that gentleman did not volunteer to give these lectures. On the contrary, when the committee of the society had decided to adopt Mr. E. Turner's suggestion, and inaugurate a series of lectures to plumbers, the speaker applied to Mr. Hellyer as the person best qualified to deliver such a course, but he at first declined on account of his health and pressure of business. The committee pressed him, however, feeling that whether plumbers as a body agreed or disagreed with Mr. Hellyer's opinions, they would have the benefit of a searching, able, and honest discussion of the leading questions still unsettled. How far these expectations had been realised the audience would judge (applause), but Messrs. Eassie and Rogers-Field desired him to express their opinion that the lecturer had shown considerable knowledge of his subject. If the lectures led to further discussion and inquiry, the great object the committee had in view would have been gained, and it had been a great source of satisfaction to the society to see these lectures so numerously attended. He hoped many would compete for the prizes offered by the society, and he could assure them that every effort would be made to secure practical and theoretical competency as well as impartiality amongst the judges.

Mr. HELLYER, who was greeted with warm applause, said, when solder was only half-heated it would not run freely, and he feared his tongue was not likely to be fluent, as the discussion had not been of a character to warm him much. No one had a right to hold opinions on sanitary plumbing unless they were based on good grounds. His views could not be shaken, for they were based on the solid rock of practical experience. Cows were an advantage in hundreds of cases, as they helped to increase the up-current. He had tested this at the cost of £200 or £300, and therefore was certain of what he advanced. Something had been said about society men and non-society men, and their relative skill, but in his firm they never asked the question; so long as a man was honest, industrious, and steady, that was all they wanted. In a letter to the BUILDING NEWS, Mr. Davies had said the best work the lecturer exhibited in that room was done by a society man; but this was a mistake, as the man in question had left the society about eight months previously. What he had meant to say was that the society was not particular enough as to the qualifications of a man before admitting him as a member. He was glad Mr. Davies had found out the way to improve the \square -trap, but even then the \square -trap held twice the quantity of water that the siphon-trap did. Mr. Court had said that he had done harm to young plumbers; but this was not so: his chief aim in coming there and lecturing was to benefit the younger men. His advice to have two pots of solder for underhand and general work only applied to large jobs, where eight or ten pairs of men were employed. In such works the time occupied often decided the question whether the master would or would not make a profit. He confessed he had put his foot into it by telling them he had made some pan-closets; but in a note to the circulars he put the warning, "This closet is totally unfit for use." Indeed, he had only made about thirty in the last two years, and then under pressure. In the hotel in question he explained the disadvantages, but was told the building was to be largely used by foreigners, and that the proprietor had pan-closets fixed in the portion already occupied, and preferred them. Mr. Buchan had supported what he had said as to siphon-traps with the weight of his experience, which was very valuable. The trapless closet, so strongly recommended by Mr. Collins, must have a very short arm, or illness might occur in the house. The majority of people would not, he feared, keep it so clean as was necessary. The owners of houses were finding out that their property was enhanced in value by being "well-drained and well-plumbed," to quote an

Americanism, and the occupiers were also learning the importance of these matters. Since it was a question of health or disease nothing should be allowed to stand in the way of plumbing progress.

Mr. J. HART asked if the competition was still open for plumbing specimens; because if so it was unfair towards those who had exhibited at the recent sanitary exhibition.

Mr. W. H. COLES, secretary, said the subjects for the society's competition would be announced on the 15th September, and work must be sent in by the 30th September.

Several competitors urged it would be unjust that other plumbers should have the opportunity of entering now, after seeing the new ideas embodied in the specimens already sent to the Sanitary Exhibition at South Kensington, and Mr. Coles and the Chairman having failed to meet the objections, Mr. Collins replied, showing that the competitions were distinct. That just closed at Kensington was for extra prizes offered by Mr. Hellyer; that, the conditions and subjects of which were to be published on September 15th, was for prizes offered by the National Health Society, and specimens sent to Kensington could be re-entered for this competition, and so would stand a double chance. The meeting closed with formal votes of thanks to Mr. Hellyer and the Chairman.

CAMBRIAN ARCHEOLOGICAL ASSOCIATION.

WE referred briefly last week to the proceedings of this association on the two concluding days of its annual meeting, and now append a fuller report.

On the Thursday the party reached Wenlock by breaks from Stretton, and proceeded thence by train to Buildwas. Visiting the Abbey, Mr. Allport Leighton produced a plan of the original buildings, so far as they have been traced or can be conjectured. The abbey was founded in 1135, by Roger de Clinton, Bishop of Chester, for Cistercian monks, and dedicated to St. Mary and St. Chad. The monks were silent, stern, austere, and plain—there was no elaborate sculpture about their buildings, and no splendid shrines. The church was cruciform, 163ft. long and 26ft. wide, with nave, central lantern-tower, chancel, north and south transepts, and chapels. The nave was 70ft. long, and consisted of five bays. The arches were slightly pointed, and the period Transition Norman. The pillars were simple, massive, round, with square indented capitals, and cushion and mouldings, which varied slightly, and only ran around one half the circumference. The clerestory windows are round-headed, deeply splayed, and the shafts have sculptured capitals. The nave and aisles were not vaulted. There was no west door, but a flat buttress between two lofty windows. That end of the church was probably appropriated to the lay brethren and the infirm monks, the aisles being for strangers. At the west end there had been a wooden gallery of the 15th century to connect the aisles, so that strangers could pass from side to side without interfering with those in the nave. The nave was separated from the choir by a rude screen dividing the two eastern bays from the rest. The lantern-tower rose but slightly above the high-pitched roof. The arches sprang from brackets, and there was a staircase from the south transept which led into the tower. The chancel was the oldest part of the existing building, but had been altered very much. The chancel and chapel were groined. The east end was square, and without aisles. At this end was a triplet of lofty round-headed windows, which were originally in two tiers. The window on the south side had also been lengthened; that on the north side was untouched. There was an aumbry and piscina. In each transept were two chapels, those to the north transept being the most perfect. In the north transept is also a door leading into the adjoining sacristy, dormitory, and cloisters. North of the sacristy is the chapter-house, at a level of 5ft. below the church. This is oblong, with round-headed doorway, a round arch on each side, with chevron mouldings. The apartment was vaulted in nine compartments on four slender columns. The capitals and corbels were simple but various. There were also some sepulchral crosses in the chapter-house of the date of the 13th century, and it would be ob-

served that the windows had not been glazed. Mr. Leighton also pointed out the position of the dormitory and cloister, and referred to Buck's view of the building in 1731, which was pronounced not to be very accurate. North of the cloister was the refectory with butteries and kitchen and the guest-house, where true hospitality was ever extended to the poor wayfarer and stranger. North of the cloister was a passage or slype, and next the hall, of three bays with round pillars, communicating eastward with the infirmary chapel and court. Still north was the hall of the infirmary of two bays separated by four short round pillars of the 12th century. The south bay has the table-hall, and in the northern bay were beds for the sick and infirm. Eastward were the infirmary lodge and the abbot's lodge. Here there were tiles of the 15th century, and there was also a portecullis. Near was a subterranean passage which led to an underground chamber which was presumed to be the place where, in troublous times, the neighbouring families took their deeds and other valuables for concealment.—The party returned by train to Wenlock, and then visited the church. At the west end of the nave, but inside the tower, was a feature in regard to which, as time was pressing, no one ventured to offer an explanation. It consisted of an arcade, with some beautiful carved work, and a casual glance seemed to show that the tower had been built up against the other masonry. Inside the church, under the gallery, was a small Saxon arch. The breaks having been again occupied, the party drove over Wenlock Edge, up Harley-bank, and, turning to the left, proceeded towards Acton Burnell. The castle was glanced at, and then the church. Entering the vehicle again, the party drove to Leebotwood, and thence proceeded by train again to Stretton.

On Friday the party reached Shrewsbury by train, and the breaks which awaited them at the station conveyed them to Haughmond Abbey. Mr. Leighton here pointed out the very beautiful arch and doorway, which, he said, was all that remained of the church. The doorway was the entrance on the south side. The church itself was destroyed, but the foundations had been traced, so that the form of the building had been ascertained. It was said that stones were brought from Wroxeter to build the church, but he did not know that to be a fact. He did not know what had since become of the stone. The adjacent tombstones, now inclosed in iron railings, were about the 13th century. There was on one a cross rising from the shield, on which, no doubt, the arms had been emblazoned. The high altar must have been somewhere near. Mr. Leighton then pointed out what he believed to have been the lavatory, and then the chapter-house, and, in reply to a question, said he supposed the old font the latter contained must have been found among the ruins. Part of the chapter-house had been modernised by the Barkers, who utilised it as a dwelling. The arches and figures below were examined with a good deal of interest. Mr. Leighton then pointed out what he believed to be the abbot's refectory, but what has been said to be the infirmary. One of the arches he believed led to the buttery and the other to the kitchen. Adjoining the refectory were the abbot's lodgings. The party next visited the old well near, with its covering of masonry. The party then drove towards Wroxeter, and, arriving at this interesting relic of the Roman occupation of England, Mr. Leighton pointed out the three arches in the portion of the walls which remains, and also a hypocaust, the construction of which he explained. As to the date of the wall they had no clue, except that a silver coin of Trajan had been found among the mortar.

The party next proceeded to Wroxeter Church. Here there was a very massive old font, near the doorway, and, in other parts of the church, monuments to Sir Thomas Bromley and wife, dated 1558, and another to Sir John Burber and wife, dated 1618, the figure of the former being in armour. On the other side of the church, in the chancel, was another very fine tomb, with two figures and the inscription:—"Here lyeth the bodye of Sir Rychard Newporte, Knyghte, which dyed, beinge one of the Queen's Majesty's Counsell in the Marches of Wales. Deceased the 12th daye of September in the year of Our Lord God 1570 and Dame Margaret his wyfe which deceased the — in the year of Our Lord God —." It was suggested, in reference to the blanks, that the tomb was erected prior to

the wife's death, and the blanks never filled up. Underneath were figures of the members of the family of the above, and one who died in infancy was wrapped in swaddling clothes. Inside the church was a curious string-course, running around the chancel-end. In the garden of the Vicarage near, was a summer-house composed of stones from Wroxeter, and among them were some very fine specimens of Saxon work. The party then returned to Shrewsbury, where the inspection of the Museum afforded evident pleasure, but there was a very general expression of regret that more commodious and better accommodation cannot be obtained for the display of so interesting and valuable a collection. Mr. Jebb produced for the inspection of the visitors an ancient jug, which was found recently near Ditton Junction Railway Station, near Rumcorn, by Mr. Webb, of Crewe, in sinking a well. A piece of Samian ware was also found, and two coins. The jug is of the 12th or 13th century, and was found 12ft. from the surface. There was an old well there, and the jug is supposed to have fallen in. It is in excellent preservation. Two coins were found at the same time. One was a second brass Domitian, A.D. 96, and the other a second brass Nerva, A.D. 98.

In the evening the party returned to Stretton by train, and a meeting of the members subsequently took place. Mr. Richard Williams, of Newtown, exhibited "the Towyn incised slate," which has of late excited so much interest among archaeologists. This slate, which is very curiously marked with figures, was discovered in a field near Towyn about eighteen months ago, about 3ft. below the surface of the ground, and was, at the instance of Professor Rhys, referred to Mr. J. Park Harrison, a gentleman who had previously acquired celebrity on account of his painstaking researches in connection with the Easter Island tablets and the markings on the chalk in the Cisbury pits. Mr. Harrison was so impressed with the curious nature of the engravings that he, with Mr. Williams, devoted several days last spring to excavating the ground where the slate was found, the result being that extensive ruins were discovered of what are supposed to have been dwellings of Irish settlers, or Marauders, in the 4th or 5th century, as well as numerous stone and iron implements, bits of pottery, and animal and human bones. A full account of these discoveries, with illustrations, is in preparation by Mr. Harrison, and, at the request of the committee, Mr. Williams permitted Mr. Worthington Smith to make an exact drawing of the slate and its inscriptions.

SUSSEX ARCHEOLOGICAL SOCIETY.

THE last excursion of the above Society to Ashburnham will, according to the report in the *Sussex Advertiser*, long be remembered by the members of the Sussex Archaeological Society as one of their most enjoyable and interesting "outs."

The gathering place was at Pevensey, whither the members with their friends flocked from all regions, some coming from as far as London. A large number assembled, to be further reinforced at Ashburnham, where about 350 persons mustered in front of the church. Nine vehicles of various dimensions were kept in readiness for conveying the party from Pevensey to Ashburnham, and these proved none too many. The arrangements for the excursion had been made by the Sub-Committee, consisting of the Honorary Secretaries, Rev. W. Powell, of Newick, and Mr. F. Barchard, of Horsted Place, and Mr. Robert Crosskey, Mr. J. C. Lucas, and Mr. Griffith. The train reached Pevensey at about 11 o'clock. The visitors repaired first to Westham Church in the vicinity of the station—a plain, but rather interesting church—over which the party were conducted by the vicar, who made a most audible cicerone. The church, which is a large stone structure, built partly in the Decorated style of English architecture, dates back to the year 1539. It consists of a chancel, nave, and two chapels, that on the south being dedicated to St. Katherine. From Westham the party proceeded to the fine ruins of Pevensey Castle, which is one of the most perfect of castellated remains of Roman origin. The outer walls of the castle inclose an area of about eight acres, and are almost 20ft. in height. In the interior is a smaller fortification, of a quadrangular form,

with round towers, and was at one time entered by a drawbridge. The circumference of the outer walls is about 260 rods, and must at one time have been of immense strength. Many an archaeologist cast a longing eye on these remains, and one could read in the expression of his face that he could content himself amidst the ruins without going any further. A few of the party, who had made good use of their time, went on to Pevensey Church, a fine and interesting structure of considerably greater age than Westham, and which was much admired. After about half-an-hour's drive, revealing some interesting sights in the distance, such as Hurstmonceux Castle, which is said to be one of the oldest brick buildings in the county, the seemingly small, but scattered village of Wartling was reached, and a halt was made to inspect the little church, which lies far away from the main portion of the village, in one corner of the parish something like five miles from the opposite end. The wooden spire is rather a rarity in Sussex. The next ride was from Wartling to Ashburnham. The Vicar (the Rev. Rose Fuller Whistler) was waiting outside the church, and proceeded at once to show the visitors over the church, explaining its various features of interest. The church was rebuilt in 1663; and one of its most remarkable features is that in all of the windows the mullions are of oak instead of stone. The Vicar read a paper on the church.

The party were next conducted to the mansions of the noble Earl of Ashburnham, where they were shown through the various apartments. The party entered by the west door, in the entrance-hall of which are hung several very fine portraits of the Earl's ancestors, and other celebrities of days gone by, amongst whom we noticed King Charles I., Queen Elizabeth, Mary Queen of Scots, Prince Rupert, and the Earl of Marlborough. There were also in the hall several miniature coats of mail, old-fashioned muskets and pistols, and other relics of ancient warfare. The majority of the portraits in this room are by Sir Peter Lely and Sir Joshua Reynolds. The manuscript library contains some very fine specimens of ancient manuscripts dating back as far as the 4th century. The next room was that of the main entrance. Here were hung Rembrandts and Vandykes, and pictures by other celebrated artists, such as Salvator Rosa, and Gainsborough; but the chief object of interest was a little glass case in which were deposited the watch and underclothing which King Charles is supposed to have worn on the day of his execution.

The dinner took place at about half-past three at the George Hotel, Battle.

The speeches concluded, the majority of the party betook themselves to the vicar's residence, where the Rev. R. F. Whistler had many things of archaeological interest to show them, among which was an ancient iron violin, which is 19in. in length and 3½in. in width. There has been much discussion as to the origin of this violin; and the Suffolk Archaeological Society, who had it for many years, came to the conclusion that it was made some time during the reign of Henry II. Among the collection was also a fleshbook in very good preservation and also an immense spur, such as was used by the knights of old. Another very interesting relic was a portrait of one Isaac Ingall, who died in 1795 at the good old age of 120. The inscription on the brass plate which is attached to it says, "Sir J. W. Webster caused this portrait to be painted." It had been hoped that the party would have been able to have visited some of the old smelting furnaces, which were still kept in use during the lifetime of the late Earl of Ashburnham, but as they were distant some two or three miles from the vicarage, and as the time for the return journey was drawing near, it was found impossible to do so, but it is hoped that on some future occasion the members of the Society will have an opportunity of seeing them, and also other places of interest in and about the neighbourhood. The return journey was commenced about 6.20.

SCIENCE AND ART DEPARTMENT.

THE twenty-eighth report of the Science and Art Department of the Committee of Council on Education has been issued. It shows that the number of persons who during the year 1880 attended the schools and classes of Science and Art in connection with the department are as follows, viz.:—60,871 attending Science

schools and classes in 1880, as against 59,519 in 1879, and 837,308 receiving instruction in Art, showing an increase upon the previous year of 41,864. At the Royal School of Mines there were 25 regular and 175 occasional students; at the Chemical Department Science Schools, 245 students; at the Metallurgical Laboratory, 79. At the Royal College of Science for Ireland there were 20 associate or regular students, and 38 occasional students. The lectures delivered in the Lecture Theatre of South Kensington Museum were attended by 4,702 persons. The evening lectures to working men at the Royal School of Mines were attended by 1,800 persons, being 626 more than last year; and 230 science teachers attended the special courses of lectures provided for their instruction in the new Science Schools at South Kensington. The various courses of lectures delivered in connection with the department in Dublin were attended by about 736 persons. The total number of persons, therefore, who received direct instruction as students, or by means of lectures, in connection with the Science and Art Department in 1880 is 906,771, showing an increase as compared with the number in the previous year of more than five per cent. The attendance at the Art and Educational Libraries at South Kensington and at the National Library in Ireland in 1880 has been 84,184, a decided increase over that of last year. The museums and collections under the superintendence of the department in London, Dublin, and Edinburgh were last year visited by 2,332,443 persons, showing a decrease of 167,321 on the number in 1879. It should, however, be observed that the number of visitors to the South Kensington Museum shows a large increase, the numbers being for 1879, 879,395, and for 1880, 981,963. The returns received of the number of visitors at the Local Art and Industrial Exhibitions, to which objects were contributed from the South Kensington Museum, show an attendance of 696,541. The total number of persons who during the year 1880 attended the different institutions and exhibitions in connection with the department has been upwards of 3,935,155. This total, compared with that of the previous year, presents a decrease of 8,552. The expenditure of the department during the financial year 1880-81, exclusive of the vote for the Geological Survey, which was £21,717 12s. 11d., amounted to £312,963 17s. 10d.

PARKES MUSEUM INTERNATIONAL MEDICAL AND SANITARY EXHIBITION, 1881.

THE Medical and Sanitary Exhibition organised by the committee of the Parkes Museum was open for the last time on Saturday, August 13th, when the number of visitors, exclusive of season ticket-holders, was 1,221, making a total of 24,333 visitors for the four weeks during which the Exhibition has been open, allowing only for one visit by each season ticket-holder. During the day the secretary, Mr. Mark Judge, visited the different exhibitors for the purpose of ascertaining their opinion as to the success of the Exhibition. The exhibitors generally expressed themselves as well satisfied with the result, some going so far as to say that they had done an exceptional amount of business owing to the fact that a very large proportion of the visitors had been either medical men, architects, or engineers. The representatives of the exhibitors who have been in daily attendance during the Exhibition marked their appreciation of the arrangements made for their convenience by presenting, on Saturday, a small purse of gold to the superintendent, Mr. Smithson. The closing of the Exhibition was taken advantage of by the St. John Ambulance Association to give a demonstration of ambulance practice, and during the afternoon a large number of the visitors assembled in the conservatory to witness the practice, which was conducted by Major Duncan, Mr. Cantlie, of Charing Cross Hospital, Mr. Furley, Dr. Crookshank, and Surgeon-Major Baker. Prizes were competed for by squads of the Grenadier Guards, the Finsbury Rifles, and the Metropolitan Police. Mr. John Eric Eriksen (the chairman), Dr. Poore, Dr. Steele, Mr. George Godwin, Mr. Rogers Field, and other members of the Exhibition committee were present during the day. It is expected that the prizes which

have been awarded will be distributed at the annual meeting of the Parkes Museum, in the autumn.

ARTISANS' AND LABOURERS' DWELLINGS.

THE report of the Select Committee on the working of the Artisans' and Labourers' Dwellings Improvement Act, 1875, and the amending Act of 1879, is only submitted to Parliament as an interim report. The Committee have been unable to complete the examination of witnesses, and after reporting the evidence, they recommend the reappointment of the Committee next session. It is virtually admitted that the operation of the two Acts has not realised the expectations of those who promoted them; and, indeed, in many towns they are simply a dead letter. The explanation is to be found in the fact that the improvements contemplated by the Acts cannot be effected without placing a serious charge, in one form or another, on the rates; and, with rare exceptions, the local authorities have shrunk from exercising the powers which the Acts place in their hands. As an interim report the Committee suggest:—(1st) that the confirming authority should allow the immediate demolition of any houses closed by the local authority; (2) that the confirming authority should have power to assent to the basement and ground-floor of any building being let as shops or workshops; and that, in considering the amount of accommodation to be provided for the working-classes displaced by any scheme, the confirming authority should give a liberal interpretation to the relaxing power in the 4th Section of the Amending Act of 1879, and take into account the facilities of transport to a reasonable distance, as part fulfilment of the obligation to provide equally convenient accommodation; and (3) that the local authority should give every facility to purchasers by simplifying conditions of sale and otherwise.

EARTHWORKS IN CENTRAL CUMBERLAND.

IN a letter to the *Carlisle Journal*, "R. S. F." (initials which may be recognised as those of a widely-known antiquarian writer, resident in the merrie city) describes the works of excavation which have been carried out during this summer by Mr. Robinson, of Maryport. Operations were begun at a Roman camp below Cærmot, a mound overlooked by the Ordnance surveyors *in toto*, though described by West in his "Guide to the Lakes," and was probably the "camp in the parish of Ireby," mentioned by Camden and Blome. The credit of its rediscovery belongs to Mr. Jackson, F.S.A., who has shown that the Roman road from Old Carlisle to Keswick runs through the site. A careful survey, made by the writer, under the guidance of Mr. Robinson, showed that the camp is square with rounded angles, and measures about 160 yards by 140. It is defended by three ramparts of earth and two ditches, extremely well defined on all sides but the east, where the modern road to Bewaldeth has encroached upon them. The east gate is in the centre of each side, and the Roman road to Keswick runs through the north and south gates. Apparently this road went to Keswick by the east side of Bassenthwaite Lake; it is to be wished that some antiquary would trace it. The spade and picker did not reveal the presence of stone in the ramparts, and the paucity of remains found indicate that the camp was not long occupied—probably only while the road was being made. The garrison was then reduced from a cohort to a century, and a new camp was formed in the north-west angle of the old one. For two sides of the new camp, the triple ramparts of the old camp served; on the east side a ditch and rampart were also made, on the site of the road through the old camp, joining the east and west gates. The west ditches of the old camp were continued and turned through the old west gate, one being continued as the ditch just mentioned, and the external one being stopped immediately after rounding the angle. The engineers seem to have thought it unnecessary to defend the new camp with the triple ramparts and double ditches of the old, and so to have contemplated a mere temporary occupation. Such seems to have been the duration of occupation of both

camp—within whose areas the foundations of buildings have not yet been found. But immediately outside of the north gate of the large camp Mr. Robinson bared the foundations of two small rectangular chambers, the lower courses of masonry being in, but they do not present any very distinctive Roman character. The buildings, be they Roman or not, have been roofed with lead, and were destroyed by fire. Mr. Robinson took out more than three stones weight of lead that had run into the soil, and more yet remains. Quantities of iron nails, in a decomposed condition, were also found, and much charcoal.

A camp is marked on the Ordnance Map near Snittlegarth, and of it Mr. Robinson has made a ground plan. It is a most singular place. On a plateau of a hill, well sheltered on three sides by rising ground, and with a lovely view to the south, a rectangular piece of ground, about 80ft. by 30ft., has been isolated by a trench with regular scarp and counter-scarp. This trench is 12ft. broad at bottom, 23ft. at top, 5ft. deep, and the scarp and counter-scarp 9ft. One thing is puzzling—What has become of the earth taken out of this trench?

The Ordnance map marks three circular camps on Aughtertree Fell. Circular inclosures are not uncommon in the North. Besides the large one at Mayborough, near Penrith, there is and at Kirkby Stephen; another near Hayton, Carlisle; one called Tower-tye, in Naworth-park; instances also exist at Triemau, at Haltwhistle, at Walwick Chesters, in Yorkshire, in Wales, Ireland, &c. Their use has locally been much disputed, some authorities being of opinion that they are prehistoric, and have protected settlements of neolithic men; others that they are of later date and are mere cattle-kraals. But Mr. Robinson seems to have proved the Aughtertree Fell circles to be prehistoric, for in a tumulus near he has found no fewer than twelve urns of ware of the usual British type, containing calcined fragments of bone. These three circles at Aughtertree are not on the top of a hill, but on the slope of one. Each is about eighty-five yards in diameter, and is surrounded by a ditch, which must once have been about 6ft. deep, the earth from it forming a rampart within the ditch. Each circle has had one entrance; one, however, seems to have a supplementary inclosure at one side of it, and this circle is divided into compartments by radiating stone walls, similar to the stone ones at Hugill, near Ings. The entrance to one circle is rudely paved. From the vicinity of the tumulus, its connection with the circles may be conjectured. Other tumuli must have existed in the neighbourhood, but the external traces have perished under sub-aërial denudation.

A mile or two further on, at Thistlebottom, exists a small square Roman camp, which has not yet been examined. A larger one is near Overwater. The position of these two in and their connection with the general Roman system of grasp on Cumberland, "R. S. F." adds, remain to be worked out; the connecting roads must be explored.

CHIPS

Mr. Robert Morgan, C.E., an inspector of the Local Government Board, held an inquiry at Reigate on Friday, into an application from the town council, for sanction to borrow £5,000 for works of separate drainage for storm water. Evidence was given showing that the large volume of storm-water militated seriously against the success of the sewage-farm, and it was therefore intended to dispose of it by a separate system. No opposition was offered to the proposal, to which the inspector appeared to be favourable.

The workmen in the employ of Messrs. Phillips and Powell, and of Mr. G. Wiltshire, builders and contractors, of Swindon, combined on Saturday week for their annual excursion, when the party, numbering 200 hands, besides friends, proceeded by special train to the Wye Valley, proceeding via Gloucester, Ross, and Monmouth, staying to visit the ruins of Tintern Abbey and Chepstow Castle, and the Wyndeliff, and returning by way of Lydney and Gloucester.

The parish-church of Honeybourne, Worcester-shire, was reopened last week, after restoration.

The drainage and sewerage of the town of Newmarket, Cambs., is on the point of completion. The contract has been carried out for the local board of health by Mr. Hook, of Soham, from the plans and under the supervision of Mr. Clark, their engineer.

THIRD PREMIATED DESIGN FOR THE EXCHANGE STATION,
LIVERPOOL.—ST. MARGARET'S, KIRKCALDY.—LAHORE
CATHEDRAL.—OLD WORCESTERSHIRE HOUSES.

OUR LITHOGRAPHIC ILLUSTRATIONS.

THE EXCHANGE STATION, LIVERPOOL.—THIRD PREMIATED DESIGN.

This design, submitted in the recent competition by Mr. Thomas Mitchell, F.R.I.B.A., was awarded the third premium. We noticed the design at length last week, on p. 190.

ST. MARGARET'S, KIRKCALDY.

This house, of which we give a perspective and first-floor and ground-plans, has been erected from the designs of Mr. R. R. Anderson, A.R.S.A., of Edinburgh.

LAHORE CATHEDRAL.

The foundations for a new cathedral at Lahore were put in some time ago, but the present design is on a much more dignified scale than was at first proposed. The old foundations have, however, been utilised by Mr. Scott, the architect, as far as possible. The material of the walls is almost entirely of brick, red brick facing being used both within and without. Nearly all the mouldings also are of red pressed bricks—the local stone, being extremely hard, and having to be brought from a considerable distance, is used as sparingly as possible. The cathedral is groined throughout with brick arches, the ribs being moulded, with stone springers, &c. The choir is apsidal on plan, and has an ambulatory. The walls of the nave and choir are strengthened by flying buttresses. The windows are very small because of the intense heat and light—those in the clerestory of the nave, transepts, and choir are set back very nearly to the inside face of the walls, and have deeply recessed openings with overhanging arches carrying the walls and parapets on the outside. The windows of the lower portion of the building are provided with wooden shutters. The roofs and fittings will be of teak. The roofs will be covered with small red tiles made in the neighbourhood, they being the only material which will withstand the great heat of the sun. An organ-chamber is provided over the first bay of the north choir aisle, which is groined in two stages, and projecting stone galleries look into the choir and north transept. The work is being carried out by native workmen, and is now considerably advanced.

OLD WORCESTERSHIRE HOUSES.

The selection of drawings forming the double page which we give to-day—by way of illustrating the excursion of the Architectural Association, some particulars of which are given on page 245—are taken from Mr. W. Niven's

admirable collection of etchings of the old manor-houses of Worcestershire, published a few years ago, and now out of print. The volume was the first of the similar volumes published by the same architect of Warwickshire houses, including the monograph of Aston Hall, all of which works have been favourably reviewed by us at the time of publication. The two bottom subjects, Eastington Court and Middle Littleton Manor House, were not included in the programme of the week's excursion; but inasmuch as they well illustrate the stone-constructed style of house of unimportant character in Worcestershire, and also the more ordinary manner of timber-construction, with detail of the best kind, we have thought them well worthy of illustration on this occasion. Eastington Court has of late years been rendered suitable for modern use, and is occupied as a farm-house, being the property of E. G. Stone, Esq. The bargeboards are richly carved with the vine, and grotesque heads decorate the spandrels of the porch. A good oak screen remains in the hall in its original position. The house is about three miles from Upton-on-Severn, and is situated in the parish of Longdon. Middle Littleton, in Upton-Snodsbury parish, has never been of much size or importance, and is of 16th-century date. The masonry is particularly good, and the design, though plain, is admirably treated. A fine tithe-barn, nearly equal to the celebrated one at Bredon, stands near the house, and is worth examination. The other buildings here shown are described in our account given of the proceedings in the order in which they were visited.

CHIPS.

An inquiry was held at Penzance on Tuesday week, before Mr. S. J. Smith, Local Government Board inspector, respecting an application from the town council for sanction to borrow £1,250 for rebuilding a portion of the sea-wall and esplanade, opposite Marine terrace, washed down during the storms of last winter, and £1,000 for completing the work of street-improvement in Morrabs-road.

The first rails were laid last week at Swansea, of the Cwmwrla section of the tramways extension in the Carmarthen-road. The contractor is Mr. E. Everingham.

The local board of Cheston adopted, last week, plans prepared by Mr. Haslam, for the extension of the gasworks in that town.

A mural brass commemorating the restoration of the south aisle and porch of Cherry Hinton parish church, as a memorial of the late Rev. Dr. H. W. Cookson, master of St. Peter's College, Cambridge, has just been placed in that church. It was designed by Mr. G. G. Scott, M.A., and was executed by Messrs. Burlison and Grylls, of Newman-street, London, W. The chancel of this church is to be restored next spring, when a new pulpit will also be erected.

The rural sanitary authority of St. Austell, Cornwall, have instructed their surveyor, Mr. Sambell, to prepare plans and estimates for supplying Polgooth with water, from springs on the grounds of Sir Chas. B. G. Sawle, which have been granted at a nominal rent.

Mr. A. A. Bradbury, late head-master of the Hanley school of Art, has been elected to a similar position at Chesterfield, from whence Mr. T. C. Simmonds has gone to the Glasgow school of art.

The chapel of St. Michael-on-the-Downs, near Wantage, was reopened on Saturday week, after restoration, from the designs of Mr. W. Butterfield. The new works include a new bell-cote with bell, cross on east-end gable, encaustic tiles, the gift of Messrs. Nulton and Co., in chancel, renewal of nave-floor, and erection of vestry. Mr. John Wheeler, of Wantage, was the builder.

The town council of Evesham adopted on Wednesday week, plans prepared by Mr. George Bower, the gas-engineer, for extensive additions to the gasworks, rendered necessary to meet the increased consumption, but adjourned for a fortnight coming to a decision as to the scheme prepared by Mr. McLandesborough, M.I.C.E., of Cheltenham, for a new water supply from the Broadway wood spring, estimated to cost £10,250 in execution.

The Hull board of guardians last week appointed Mr. W. B. Thompson, of that town, as architect for the proposed extension of the workhouse by a new wing on the men's side.

An organ to cost £650, and to be built by Mr. Nicholson, of Worcester, has just been promised to the modern church of St. Mary Magdalene, Sansome-walk, in that city, by a local gentleman.

PALLISER'S USEFUL DETAILS.*

ANOTHER work on details has been sent to us from America. Messrs. Palliser, Palliser, and Co., of Bridgeport, Conn., U.S.A., who are both the authors and publishers, aim at supplying large scale and practical drawings of details for the use of building artificers and others, to meet the demand for the requirements in the prevailing styles. Good practical details of construction are no doubt of more importance in America than in this country, and we must credit the authors with the very best intentions of supplying the demand by the issue of the present large folio of plates in Gothic and other modernised styles of work. As modern English taste in these matters is so widely divergent from the Gothicised designs now prevalent in America, it would not be fair for us to express an opinion on the merits of the present work. Such a detail as that shown for entrance-gates would be rather costly. The flat archway abutting against the pier would, we fear, have the effect of pushing over the latter, or at least not improving the verticality of so slender an erection of masonry, and the authors have wisely avoided hanging the gate from the pier by throwing its weight on a runner. Some of the smaller wooden gates and fences are suggestive, though we cannot approve of so many curved braces, stop-chamfers, and incised ornaments. The designs for inside-doors are, to our minds, spoilt by decoration of a questionable sort. The cut and chamfered panels, the struts in the panels, and the quadrant devices are now meaningless, and only remembered as a few of the vagaries of the late Gothic mania. A sheet of details of chimney-pieces and overmantels will be found useful to joiners and others, and the designs for sideboards, writing-desks, book-cases, &c., on plate 5, are free from extravagances. The ends of some of the cases and cabinets would have been less open to objection if the notchings had been omitted, and surely it is a spurious sense of ornamentation which carves and indents the constructive framing of a piece of furniture.

A more sensible sheet of details is given of timber gables and framing, and also of tiled and shingled gables, which will be found of service. Another useful drawing of details shows a porch with balcony over, and a verandah; gable-balconies, bracketted balconies, with stencilled relief in panels, and various other kinds of wooden construction are given in the following plates, in which details of rafters' feet, guttering, windows, and the manner in which the window-sills are framed into the studwork are indicated.

The most useful part of the work before us are the plates describing handrailing, with instructions for working the details of bank- counters. Besides woodwork, details are furnished of brick and stonework, terra-cotta dressings, conservatories, cupolas, chimneys, church seats, and various other fittings and adjuncts of buildings. The details are generally drawn to a scale of $\frac{1}{4}$ in. to 1 ft., and in all there are no fewer than 40 plates printed on thin paper. Being to a working scale, they will be found of service to carpenters, joiners, and masons, and we have no doubt Messrs. Palliser's work will be duly appreciated by the American workman. The price of the work is 12s. 6d.

The village church of High Tooton, Lincolnshire, was reopened on the 3d inst., after further restoration, including boarding the internal ceiling, and the erection of the Taylor memorial reredos. In the latter, red Mansfield stone is used for the base, Ancaster stone for the upper portion, and alabaster for the panels, a pure white variety being used for the central panel, which is carved with the Agnus Dei, and mottled Derbyshire for eight side ones, in which are sacred emblems. In the wings are square trefoil panels, three on either side, of yellow Mansfield stone, inscribed in legible Gothicised letters with the Lord's Prayer, Creed, and Commandments. The reredos has been erected from the designs of Mr. Edmund B. Ferrey, of Spring-gardens, Charing-cross, by Messrs. White and Sons, of Vauxhall Bridge-road, London, S.W.

The Wighton board of guardians adopted, last week, plans by Mr. J. S. Mart, architect, for new wards, to cost £250, to be erected on the west side of the workhouse.

THE ARCHITECTURAL ASSOCIATION
AT WORCESTER.—II.

ON Monday last the Architectural Association excursion party, who are now visiting Worcester, as we stated last week, began the programme of their proceedings by a visit to the Cathedral Church, where the excursionists were met by Mr. Wm. Jeffrey Hopkins, F.R.I.B.A., who gave some dates and particulars of the building and its precincts, including the remains of the Guesten Hall and Edgar Tower. Originally, Worcester Cathedral was dedicated to St. Peter, and the first Bishop Bosel is recorded as having fixed his seat here towards the close of the 7th century. He was followed by a succession for three centuries, during which period little seems to have been done, when Oswald, helped by King Edgar and Archbishop Dunstan, completely revolutionised the Secular College of St. Peter, and established a monastery dedicated to St. Mary the Virgin, and many of the secular clerks or priests became its members, the new monastic church being completed about A.D. 983. This building was destroyed before many years elapsed by the Danes. Portions of the monastic buildings and church which followed are now to be seen, notably in the crypt, which is one of the most remarkable, as well as one of the earliest, examples of the kind in England. This is the work undoubtedly of Bishop Wulstan, who rebuilt the cathedral in 1054. His work has suffered from sieges and from fires; but to the failures of the Norman towers is also due much of its destruction. The crypt, with its many arcades, having unusually light circular shafts and singularly vaulted roof, is well deserving of notice. The radiating chapels round the apse have been destroyed, but with this exception the building is in very good preservation, and is well cared for. The only other similar examples in England are at Canterbury, Gloucester, Rochester, and Winchester, but here a special character is obtained by the numerous columns already referred to, and these were rendered necessary by the treacherous nature of the site, which is very sandy and closely situated to the Severn river. The choir is mainly of Early English date, like the eastern transepts, Lady-chapel, and choir aisles. The work is of the best period, though, unfortunately, in several particulars very much over-restored, and, consequently, in parts is very unreliable. The east-end window of five lancet lights, however, which is entirely new, is a fine work, and does great credit to the late Mr. Perkins, to whose ability as an architect it bears admirable witness. The same remark may also well be made with regard to his restoration of the cloisters, showing how capable he was to do such work when left unfettered by those who employed him, or when not interfered with by meddling amateurs. It is but just to his memory that this remark should be made, inasmuch as Sir Gilbert Scott has usually been credited with all that is good in the work of restoration here, while Mr. Perkins has rather unfairly been charged with the guilt of all that was badly done. Sir Edmund Beckett helped with some portion of the work, more especially in the rebuilding, or rather recasing, of the tower, in which work most of the old lines of the ancient tower were quite departed from. The only works carried out by Sir Gilbert Scott were the choir fittings, reredos, and screens, including the rather overdone pulpit in the nave, and the rich altar-tomb monument to Lord Lyttleton, late Lord Lieutenant of the County, erected in the north transept. The remainder of the work was carried out by Mr. Perkins, who was engaged on this restoration for more than 15 years, more than £100,000 having been expended on it. Following the Early English choir we have the Decorated nave, with its rich arcade and handsome triforium over, surmounted by an unimportant clerestory, and covered by a vaulted roof throughout. The two western bays of the nave are much earlier in date, and are of Transitional Norman character, showing, however, distinctly, both by the earlier respond and work adjoining in the aisle, that the width, if not length, of the Norman nave has been preserved. The west doorway is in very bad modern Norman, and the large west window, filled with Hardman's glass in 1875, represents "The Creation." The same firm decorated the groining of the choir, under the direction of Sir Gilbert Scott, with flying angels, seraphim, Greater and Lesser Prophets, virgins, martyrs, and the rest, filling out the spandrels with foliage

and scrolls in an expensive and necessarily elaborate manner, the whole being quiet in tone if not eminently satisfactory. The cloisters are of Perpendicular date, having some quaint openings in the outside piers, and provisions for the old lavatories remaining. The Cathedral consists of choir with aisles, Lady-chapel and aisles, upper and lower transepts, and these are of the same height throughout; nave with aisles, northern porch and central tower, which is 170ft. high. The tower is on the same plan as the Norman one, and stands on the same site. It contains an admirable peal of fifteen bells, with a carillon machine playing thirty-five tunes, the work of Messrs. Gillett and Bland, of Croydon. The new organ is in the south transept, built by Messrs. Hill and Son, of London, like that in the choir, which latter includes most of the old one. The case of the grand organ is of very satisfactory design, elaborately carved with Flemish-charactered foliated enrichments, and angel figures executed throughout in oak, from the designs of Mr. John O. Scott. The artificial lighting of the Cathedral deserves a remark. It is effected by means of a continuous series of jets immediately over the stone string below the triforium arcade, and a most perfectly diffused and soft light is thus obtained, as in York Minster. The exterior of the building presents a very new appearance, and the old spires which occupied the angles of all the main walls not many years since, giving a special character to the church, have unfortunately been restored in a very different manner; commonplace low pinnacles doing duty in their stead.

Leaving the cathedral, the Chapter-house was next visited. It is situated similarly to that of Westminster, and presents a circular plan inside, the octagonal form being preserved on the exterior. The greater portion of the building is Norman, having a lofty and massive central shaft supporting its roof, which from the outside is now unseen, though originally, doubtless, of conical form. The windows are of Perpendicular date. Here are exhibited the remains of old vestments exhumed in 1862, and those found in 1870, when the tomb of Bishop William de Blois was opened. He died in 1236, and these fragments are thought to be of rather earlier date than this. Drawings of those found in 1862 were included in the A. A. Sketch-book for 1869-70, by M. H. Curzon, and the De Blois vestment were published from sketches by Mr. Charles Henman in the same sketch-book, in 1870. Great regret was expressed by the visitors at the removal of the Guesten Hall—a fragment only of which now remains to show the beauty of the demolished building. The roof was ruthlessly smashed, and thrown down in heaps on the College-green, probably to have been sold for firewood, if it had not been secured by the architect of Holy Trinity Church, which was then building. The dean and chapter gave it, however, eventually for this purpose, where it now remains. Next week we shall give a drawing showing it in detail. The difficulty experienced by the ecclesiastical establishments of Worcester in providing suitable entertainment for strangers rendered it necessary to erect a separate hall, and this work was undertaken by Wulstan de Brannsford, then prior (1320). In this court the convent held their monthly court, called "Guesten Hall Court," for determining of differences between the tenants, and this custom was preserved even to the days of Charles I. Many points in this hall corresponded in treatment with the Archbishop's Palace at Mayfield, Sussex, and Penshurst Hall, Kent. Mr. G. E. Street, R.A., reported on the Guesten Hall, with a view to its restoration, and published some pen-and-ink drawings of it in 1854, when every effort was made to prevent its destruction, but all without avail, as we have already noted. The refectory was seen, with its crypt below, of Early Norman date, and the Edgar Tower was likewise shown. The fourteenth-century figure of Edgar, which occupies the niche over the gateway, is much mutilated; and only so recently as to be remembered by Mr. Hopkins, the face and front of this figure was chopped off, on the occasion of some illuminations, to make way for the trophy of gas—so little have historical monuments been valued in Worcester. The Commandery and Deanery were visited by the excursionists during the day, under the direction of the president, Mr. Aston Webb. Of the former, we gave two views last week, the small exterior on the right

hand of the plate being a sketch of the entrance to the hall; and of the former, we gave the plans, with some particulars. Later on in the day, the Royal Porcelain Works and Museum were seen, under the guidance of Mr. R. W. Binns, F.S.A., the art director of the company. No one can fail to appreciate the excellence of the work produced, or value too highly the large collection of old Worcester and Japanese ware, including some splendid Kioto and Owari porcelain, exhibited in the Museum; but for some reason or other, the new work fails to display anything like the merit in character or design of the old.

On Tuesday, an early breakfast was made, with a start from the hospitable "Star" Hotel, at half-past eight, by carriages, the destination being Tewkesbury, where the Abbey Church, of which we gave an account last week, when a plan and view were given, was described by Mr. James Fowler, F.R.I.B.A., of Louth. Calling at Severn End, the timbered manor-house, which we illustrate to-day, was seen, and also the church at Hanley Castle was visited on the way. "Severn End," situated within a few yards of the river from which it takes its name, was for many generations the family seat of the Lechmeres, and over the entrance-doorway is painted the motto "Christus pelicanus," with the Lechmere crest—a pelican, az., vuluing herself. The central block of the buildings is of timber-built construction, dating from the time of James 1st, or perhaps of Elizabeth; in Queen Anne's time brick wings were added, forming a quadrangle in front, which is entered through a gateway of some importance. The piers, which are built in courses of brick in three different colours, are surmounted, the one by a dog and the other by a lion, as seen in the view of the entrance front herewith given.

The garden-front of the house presents a most picturesque appearance with its many and varied gables. It has long since been disused as a residence for the family, and now forms a well-kept and valuable museum for Sir Edmund Lechmere's collection of old furniture and antiquities, which are guarded by the residence here of the farm steward. The drawing-room is enriched by a richly panelled ceiling, "each panel in achievements clothing," but which certainly is too heavy for so low a pitch.

The east-lead cresting to the entrance-front gables, and the old enriched lead stack-pipe heads are very interesting. Only one old plaster enriched mantel-piece remains, and that is on the upper floor. In the garden is a quaint old garden-house, or justice-room, built by Judge Lechmere in Charles the Second's reign. It was carefully restored a few years since, and is now used as a little museum. Leaving Severn-end with very many regrets, as the time allowed failed to permit the completion of a good many half-finished sketches, the excursionists reached the church with the double chancels at Hanley Castle, which "Johan Leylands" in his "liberhouse journey" thus quaintly describes: "Hanley is from Upton a mile in *destra ripa Sabrina*, and a flitt shotte from Severne. It is an uplandish towne. The castle standith in a park at the weste parte of the towne," and "Syr John Savage, who lay much aboute Theokesbyri," is mentioned as being the predecessor of "Mr. Cometon, who elene defaced it yu his tyne, beyng keeper of it after Savage." Lord Warwick used the castle as a residence, and after him the Despencers. The building was large and square, and had four towers surrounded by a moat, but

"Now not one stone remains to claim the sigh
Of passing man, save when the hollow winds,
Bending the nightshade's head or nettle rank,
Disclose some sculptured fragments damp and green,
And half immaured in earth."

The church was restored by Mr. G. E. Street, R.A., in 1858, when he built both north and south porches, the former being in wood and the latter in stone, which arrangement was the cause of some criticism. The church was much altered by Judge Lechmere, who built the present square and massive brick tower at the time he altered Severn End. The parish-chancel is now called the Lechmere Chapel, and is used as a vestry and organ-chamber; many of the Lechmere family are also buried here. Some dreadful coloured glass is in some of the windows. Those to the north aisle have a singular treatment of cusped heads not often

met with. The church and churchyard are well cared for, and round the latter are some old alms and half-timbered houses. Reaching Tewkesbury, after a drive through Upton-on-Severn, where a view was obtained of the old debased Classic or so-called Queen Anne sort of church, by the river, and the new church lately built by Mr. Arthur Blomfield, M.A., and illustrated by us last year; some two hours were profitably spent in sketching both in the abbey and about the town, where several interesting half-timbered houses are still to be seen. We hope to continue our notes next week made on the following days of the excursion, during which time Pershore, Woolas Hall, Lorton Manor-house, Huddington Court, Mere Hall, Droitwich Church, Westwood Park, Salwarpe Court, Great and Little Malvern, Madresfield Court, Ledbury, and Worcester were visited. Next week also we shall continue our illustrations.

DRY ROT IN TIMBER.

THIS disease, if we may so term it, is still a matter of doubt between naturalists who have sought to explain the production of the fungi. Some have maintained that the fungi producing dry rot are spontaneously developed; others that they are produced by seed taken up and supported in the air, until favourable conditions are presented. The fine powder which distinguishes dry rot is composed of myriads of reproductive spores of the fungus. From a mildew it assumes a delicate white vegetation, and afterwards a leathery appearance. The fungi, over different materials, are of various colours, sometimes reddish, violet, brown, at others white and grey. It is well-known that very damp situations are not favourable to the growth of the fungus. In dry situations it is found to spread more rapidly, and we have seen the side of a party-wall covered with its fibrous cotton-like texture, the roots or filaments appearing to have extended from the basement. In this case the painting of the wall was in a pulverising state, and the skirting and flooring covered by it. The situation was quite dry. Absolute wet prevents its growth, but damp combined with warmth appears to be favourable to decay.

One of the principal naval builders of Chatham Dockyard has said the destruction of timber by dry rot cannot take place unless air, moisture, and heat are all present, and that the entire exclusion of any of these three stays the mischief. Mr. Britton, in his work on "Dry Rot," who quotes this opinion, observes, "The admission of air has long been considered the only means of destroying the fungus, but as it has frequently proved ineffectual, it must not be always taken as a certain remedy." He also says the air admitted ought to be dry air, so as to absorb the moisture; it will then exhaust the fungus. But care should be taken to let the air escape, and not allow it to convey the seeds of the disease to other parts of the building. Hence the value of free ventilation behind all skirtings, dados, wainscoting and floors in the first place. At 80° Fahr. dry rot proceeds rapidly, but at from 100° to 120° it is arrested. At low temperature it is also arrested. To prevent rot, good seasoning and ventilation are essential. Charring after seasoning and coal-tar are recommended. To cure dry rot, a solution of corrosive sublimate in water (an ounce to a gallon, used hot), or a solution of sulphate of copper (half a pound to a gallon of water used hot) are good washes.

THE POLLUTION OF RIVERS.

A PAPER on this subject was read by Mr. A. Holkison, C.E., of Hexham, at the annual two days' Northern Counties' Conference on Local Government held at Gilsland, near Carlisle, last week. Mr. Holkison said he should deal with legislation on river pollution in its bearing on sanitary operations in rural districts. The subject might conveniently be divided into the two heads of water supply and removal of refuse. With regard to the former point, he thought it was evident that future legislation must be such as to materially extend the sources from which the water supplies can be abstracted. The sewage clause in the Public Health Act did not actually prohibit the discharge of sewage into streams, and only

nominal sewerage works were made in order to comply with the letter of the law. Pumping from streams of large flow was rendered no more practicable by all that had yet been done, than it was in the days of unheeded and unchecked river pollution. Manufacturers did as much damage, and were only interfered with in those exceptional cases where the provisions of the Act were invoked by aggrieved parties. Attention must, therefore, be directed to deep wells, springs, and upland gathering-grounds, according to local circumstances, and a much higher standard of purity in the water-supplies would be essential than was formerly the case. As to the sewerage question, the discharge from the outlet of places already provided with a complete sewerage system emptying into a stream could be dealt with by the Local Government Board under the Health Acts, or by other people, under the Rivers Pollution Act. On the second section of his subject, the removal of refuse, large numbers of villages, with the sewage standing in the midst of the population, were confronted with the sewage-disposal difficulty as soon as any attempt was made to remedy the insanitary conditions. He described the difficulty that would exist in such a contingency, and said he considered it absolutely necessary, especially in widely-scattered districts, to limit the total volume of liquid requiring treatment to the smallest and least fluctuating amount possible, and he would not admit rain into the sewers. The admission of rain-water necessitated increase of size, and therefore of cost, in the sewer-pipes, and it was ineffective, for just when it was most wanted, in dry, hot weather, the provision for the performance of flushing was altogether absent. The true system of sewer-flushing consisted in the frequent accumulation and instantaneous discharge of a comparatively small volume of water, as against the continuous and unaltered flow of an amount possibly a hundred or even a thousand times greater. Used in this way, he had found that a volume of water, varying from one to two gallons per head of the sewered population per day, was ample for the most liberal and effective performance of flushing operations.

THE SOCIETY OF ENGINEERS AT THE BISHOPSGATE GOODS DEPOT.

ON Wednesday afternoon a number of members and associates of the Society of Engineers paid a visit of inspection to the gigantic goods depot of the Great Eastern Railway Company at Bishopsgate. The party were received and conducted round the building by Mr. H. Wilmer, assistant engineer. The depot is so extensive, occupying as it does an area of 11 acres, between Shoreditch and Bricklane, Spitalfields, that upwards of two hours were spent in the general inspection of the place. The operations for making the depot on its present scale commenced some five years ago, when the old passenger station at Bishopsgate was removed. It is anticipated that within another twelvemonth the contractor will have completed his work. Portions of the plan have been carried out as land has been acquired, but the site is now clearly defined. Though not quite finished, the depot is in working order, and the main part in use day by day, or, to use a better phrase, night by night. It would appear that much of the traffic at Bishopsgate is nocturnal. For instance, the visitors were shown into one large office, with accommodation for 60 or 70 clerks, but only two scribes were to be seen, the explanation being that at midnight the office would be an animated scene of gas-light and bustle. The construction of the depot is carried out in a thorough manner. The old extension on the Bethnal-green side was supported by wooden piles, but these are being replaced by arches, which show some good brickwork. It may be interesting to state that a few coins came to light during the excavations, though thought little of importance to the antiquarian has been discovered. Of course, it is likely enough that at a greater depth than the spades of the workmen descended many a relic of the remote past may lie hidden. Two large markets, one for fish and the other for potatoes, are to be constructed under the spacious arches and adjoining Wheeler-street, which bisects and runs beneath the depot. In the latter market, accommodation will be afforded for no less than

15,000 tons of potatoes. It is estimated that this vast depot when finished, will have cost nearly half a million of money. At the conclusion of the two hours' inspection, Mr. Rigg, on behalf of the party, thanked Mr. Wilmer for the trouble he had taken and the explanations he had rendered; and Mr. Wilmer, in reply, expressed himself only too happy to offer every facility to the Society of Engineers to see the works of the company.

MINSTER CHURCH, ISLE OF SHEPPEY.

REPAIRS and reconstruction having been in hand during the past year, and no notice taken in the BUILDING NEWS, a few remarks from an amateur in building may be of interest to those who may be disposed to visit Sheerness.

Its situation is on a high ridge $2\frac{1}{2}$ miles distant, and every facility, which is very rare, is offered to those inspecting. Externally we notice two apartments or halls, one with an almost flat roof of considerable height, another with similar end gables, sharper, and covered with slates, the northern building having the base of a wide square tower with buttresses projecting beyond the west façade. Let us examine these three buildings. 1st. The Tower. Its west façade presents a Perpendicular entrance, with square-hooded canopy and quatrefoils in the spandrels; above this a well-proportioned Perpendicular window of the usual type, without any cuspidation; shortly above this the stonework ceases at a set-off, and we notice a sort of crotchet, surmounted by the appropriate "horse's head" as wind vane. (See "Ingoldsby Legends" for reason.) The tower is obviously very incomplete. It may be noticed that two newel staircases lead down, in circular hollows in the interior of its thick walls, one into the north church under the tower, the other now into a garden, but formerly into the monastic or nuns' buildings, all of which, except the gateway (entire) have disappeared, their stones entering into the formation of many a farm-shed. The west façade of south church presents now a single lancet, a Perpendicular insertion, a circle in the gable pierced, and traces of other and higher lancets; in fact, in plans published some time back, the architect proposed a complete Early English restoration, which Mr. Christian has not adopted, but has repaired the Perpendicular work. Coming now to the south façade, which is entirely formed of the south wall of St. Catherine's aisle, and a very roomy porch, we notice several lancets, with doubtful external stonework, probably previous repairs (?), and Perpendicular insertion higher up, breaking into the lancet areading within. The east façade, which comprises both north and south churches, is most interesting. The south presents three tall lancets; the north no window till right high up, and that a very Late one; but on the extreme right is a fine entrance-doorway from the other building, Early English, and just over its right side is a small opening in the masonry, within which, in the solid wall, are seen two stone bearings, which probably supported the wheel of bells or single altar-bell. This aperture opens into the interior by a quatrefoil in a block of stone. Along the north façade we notice nothing of importance; no external marking of nave and choir—in fact, this abuts on private property. Having now entered the spacious porch on the south side, we observe a round-headed Early English entrance, with dogtooth moulding and niche above, this having been quite concealed in the late plaster. Being now in the south church, or St. Catherine's aisle, it is found to be a single apartment, containing only the base of a wood screen as a division into nave and chancel, the upper portion having been destroyed some years back, to give a better view of what we will now describe. The tall lancets we saw externally are, inside, barely seen at all, owing to the reintroduction of the reredos of the time of Wren, itself a very handsome incumbrance—pediment, vase, and acanthus-leaves; but why in a church, with a certain amount of vacant wall-space elsewhere, it should here have been replaced, is a puzzle, as all pilasters, string-course, &c., had been previously made good. Its speedy removal will, however, be a matter of ease, unlike one-half the structures erected in stone in the present day, in similar situations. On either side of the gangway we have walked up will be noticed a long marble slab, in which is set a

full-sized brass figure; this is the well-known "Northwood Brass," and a few slight repairs have been done by Mr. Waller, at the expense of a descendant of the family. Previously these figures were close together, on a very thick stone, in the centre of the passage. To the right is the "Shurland" monument, with its fine feathered-canopy and finial; the feet of the figure, recumbent, on a horse's head amid the waves. On either side of the "Classic" altar-piece was discovered a niche, one with the fresco of a bishop with mitre, and in the other several figures and heads, bricked up. The church we have described is covered by a new open roof in pine, and is now benched; it is connected with the structure now to be described by an arcade of three chamfered arches, and alternate octagon and round pillars, and a single arch with floriated capitals, between the quasi-chancel of the south church and choir-inclosure of the north. This north church has the usual division of nave and choir, and though unusually lofty is somewhat narrow; the Nuns' choir is divided by a tall, early English arch, plain, with Perpendicular wood screen of the usual type; in this choir the monumental remains are most interesting, as also the wall arcades and sedilia, numbering only two, which have been uncovered, and it may be here remarked that this portion of the church is left with the plaster skinned.

Previous to the late repairs, this choir was divided half-way up the arch into an upper story, and used as a school for the village. One effigy here was dug up, years back, in the churchyard, and its date is somewhat doubtful. The whole church has been well concreted, having been riddled with offensive vaults quite lately. The roof, which was stated to be almost flat, was put on in 1846, as an inscription on one of the principals notes, and has required corbels and fresh trusses, and its leads repaired, while that portion east of the choir-arch has been close-boarded and panelled by the Ecclesiastical Commissioners. The font-cover is of the Renaissance type, carefully cleaned from coats of paint, though not perfect at its base.

The tower space opens to this nave by its entire width and height, in a Perpendicular arch, having a grand effect. The consideration of either proceeding a small distance higher, or repairing the present wooden cot on the stump of the tower, is deliberated, and alone remains to be dealt with. It should be mentioned that Saxon work is visible over the divisional arcade in the north church. Mr. Ewan Christian has been the architect. The dimensions are: South church: width, 30ft.; length, 75ft.; north church: width, 25ft.; length, including tower-space, 94ft.; without tower-space, 71ft.; porch, width, 15ft.; length, 16ft.

SOME ARCHITECTURAL ASPECTS OF THE EARTHQUAKE AT CHIOS.

AN interesting letter, by Mr. Joseph Thacher Clarke, Corresponding Member of the American Institute of Architects, and Special Corresponding Member of the Boston Society of Architects, now in charge of the explorations in progress at Assos for the Archeological Institute, appears in the *American Architect and Building News*, in which, after graphically describing the locality and results of the recent terrible earthquake at Chios, he concludes with the following remarks on some of the architectural lessons to be derived from the catastrophe.

Of the buildings destroyed upon Chios perhaps the only one individually known to architectural history was the Monastery of Nea Moneh, with a Byzantine church in the centre of its quadrangle which contained mosaics reputed to be the finest in the Levant.* These buildings were almost entirely overthrown, burying a great number of monks beneath their ruins. The plan of the church, which dates back to the age of the Empress Irene, was in many respects peculiar. To an irregular octagon, with three apses at the east, there was adjoined a narthex and an exonarthex, the ceilings of both being divided into domed compartments which were ornamented by the famed mosaics.

The direction of the first shocks is everywhere evident from the ruins, as well as from the ac-

counts of witnesses. A marked vertical upheaval preceded the usual lateral oscillations, which toppled over the masses of masonry thus loosened. The mechanical results of this upward movement are extremely remarkable. The heavy corner-stone of a roof-cornice was situated eight metres above the earth. Put in motion by the first shock, it jumped over the L of a building four metres broad, situated at a distance of three and a half metres from the cornice, and fell *twenty-one metres* from the spot where it would have dropped vertically. So at least affirms Prof. Dr. Christomanos, who was sent from the University of Athens to prepare a report upon the earthquake. The wooden upper story of a house in the suburbs of the capital was lifted off bodily, and stands upright in the garden, beside the original foundations, intact in all its constructive features. One man, who miraculously escaped without injuries of importance, was completely buried under the ruins of the local Casino by the first concussion, the debris above him being thrown aside by the succeeding shocks. The upright motion is further evident from its effect in chipping the rectangular edges of heavy and insufficiently cemented stones. The piers of the chief inn of the town were thus fractured upon all the lower corners from having been jolted up and down, while the balustrade and iron gratings between were sufficient to keep these supports from falling sideways.

It is by a consideration of such aspects of destruction that one is enabled to appreciate the marvellous perfection of stone-jointing customary in the best constructions of Greek antiquity. The drums of the shaft, and indeed every block of the unrivalled Doric and Ionic temple structures, were not merely doweled by upright pins, but were united as one stone by the grinding and polishing of each superposed cylinder. A fragment broken from the columns of the Parthenon by Revett severed elsewhere than at the joint between the drums, into which the point of the sharpest knife can nowhere be introduced. The earthquakes which have repeatedly tumbled Byzantine Athens to the ground, and have even overthrown columns of the Corinthian fane of Olympian Zeus, have not jarred a single stone of the three great buildings upon the Athenian acropolis from their normal positions. Some of the peculiar features of the later Greek wall-masonry here at Assos are only to be understood when compared to the ruins of Chios and referred to the great earthquakes during the reigns of Tiberius and Aurelius, which depopulated so many of the fairest towns upon this coast.*

Eugène, in the *Histoire d'une Maison*, who may doubtless be taken as an expositor of the views of one of the greatest architects of this century—the best trained, if not the most gifted, designer—describes ideal technical education as particularly furthered by a study of actual buildings, not those merely projected on paper. Especially did he "set himself to observe buildings that were crumbling to pieces, that he might discover in *anima rili* the causes of their ruin." And thus in Chios, though the destruction of the edifices has been brought about by a phenomenon of Nature, the principles of resistance which find application in building construction are exceptionally evident and instructive. The jarring and pounding of our manufacturing machines produce much the same ultimate effects as the shocks of the Chian earthquake; that the ruinous agency is in the former case weakened in force, and extended in action over a period seldom shorter than five years, does not in principle alter the architectural aspects of the question. From this point of consideration the first and most striking evidence of the ruins affirms the resistance offered to vibrations by wooden constructions to incomparably surpass that of the best masonry with horizontal bed-joints. In some houses by the water-side the stone walls were almost wholly overthrown, but crumbling away had left intact within them those rooms which had been inclosed by light partitions of studding and by the lathing of the outer wall, upon which the plastering had been applied to obviate its continual cracking from the settling of the badly-built masonry. It is further observable that the combinations of timbered construction with stone and lime in the building of walls everywhere insured good results, while, on the

other hand, wooden floorings of beams or joists were frequently shaken from their bearings in walls of masonry, and fell, carrying destruction from floor to floor. Vaulted ceilings remained uninjured in almost every instance; it was wonderful what poor and hasty constructions of this kind resisted the concussions. If, in the figurative language of the Orientals, "the arch never sleeps," it is the more alert against unforeseen shocks, and, by its continual tension and the varied direction of its thrust, better withstands a swaying movement, the wedge-shaped stones only being forced the more tightly together, so that the whole cannot fall as long as its supports remain unimpaired. In the lack of wood for the adoption of the *Chatmâr* and *Frenghish* methods of partial timbering, the turning of blind arches of considerable thickness in the body of the wall is to be recommended. One façade of a Chian house, thus strengthened, had been erected upon insufficient foundations, and was thrown by the earthquake bodily across the narrow side-street, where it leaned unbroken, having crushed the delicate wooden tracery of a Turkish bay-window. But when, as in these districts, lumber is so common that at least the floors are usually built of wood, it seems advisable to secure stability and safety from the constantly-recurring vibrations of the earth by putting all the beams at disposal into the thickness of the wall, and arching and vaulting the ceilings with bricks and small stones.

It is dreadful to think, while looking upon the deserted and blood-bespattered ruins of this once populous town, of the results which would be occasioned in our own great cities by only one of the fifty or more shocks which have overthrown the low houses of Chios. To assume the possibility of a destructive earthquake is of course to be regarded as a foreboder of impossible evils; but it must not be forgotten that shocks of considerable force have been chronicled almost every century, while lighter and almost unnoticed vibrations are of constant occurrence. We have been reminded that when a structure sways for some seconds in the same time and direction as the earth, the danger of overthrow from comparatively slight concussions is as great or even greater than from single severe shocks. No constructors have ever built with less regard for possibility of altered statical conditions than the master-builders of our tallest edifices. Every architect knows the haste and short-sighted economy with which many of our largest and most pretensions business-blocks and dwellings have been put up,—and can picture to himself the result of an earthquake, which need be no more severe than that which visited us in 1775 to destroy hundreds of thousands in an instant.

CHIPS.

Mr. J. E. Millais, R.A., has been appointed a trustee of the National Portrait Gallery, in place of the late Dean Stanley.

A new Roman Catholic chapel at Innerleithen was opened for worship last week. Mr. Biggar, Edinburgh, was the architect of the church, which is nearly 100ft. long inside, 25ft. wide, and to the point of the open roof 46ft. high. It is in the 14th century style of English Gothic. Mr. Robert Matheson, Innerleithen, was the builder.

The Cardinal Archbishop of Westminster recently laid the foundation-stone of a school-chapel at Tottenham. It is 90ft. long and 28ft. wide. It will be of the simplest kind—brick with stone facings, and will cost in erection £1,900. Mr. Francis W. Tasker, of John-street, Bedford-row, is the architect.

The foundation-stone of a new Primitive Methodist chapel was laid at Clarendon, Bath, on Tuesday week. The chapel will be built of Bath ashlar masonry, will seat 260 persons, and will measure 33ft. by 45ft. At the rear will be a school-room, 18ft. by 36ft., having in its basement five class-rooms. Mr. James Hicks, of Redruth, is the architect, and Mr. Bladwell, of Bath, the contractor. The cost will be £1,100.

The new town-hall at Staines is rapidly approaching completion. Mr. Johnson is the architect, and Mr. Brunnsden the contractor.

On Wednesday week the workmen employed in enlargement of the theatre royal, at Ward Ends, Halifax, were entertained at supper in celebration of the completion of the new stage. The work is being carried out by Mr. Cawderay, of London, and, when completed, the pit will be enlarged from 300 to 800 sittings, and the gallery to 1,000 sittings.

* Compare Dallaway, "Constantinople ancienne et moderne, et description des côtes et îles de l'Archipel et de la Troade," Vol. II., p. 78; etc.

Building Intelligence.

AVENBURY.—Avenbury parish-church, an ancient structure built on the banks of the river Frome, about a mile and half above Bromyard, has been reopened after restoration. The interior restoration consisted in taking down the old lath and plaster, and cutting a new ceiling. By this the whole of the old oak timber in the roof up to the apex (and most of which is in good preservation), now stained and varnished, will be displayed to view. The old stone floor in the nave and chancel has been taken up, and the whole relaid with Godwin's tessellated tiles. New stone steps under the altar-rail from the chancel have also been put. The old oak pews, put in on the occasion of the former restoration, have also been removed, and open seats of pitch-pine have been substituted in the nave. In the chancel four new stalls have also been put in, and a new floor has been laid underneath them. There is also a new pulpit erected in the place of the old one, and the reading-desk and lectern are likewise new. They were executed in oak, from the designs of Mr. Haddon, of Hereford. The old oak screen, which was formerly partially covered with plaster and whitewash for many years, has been completely restored and varnished, with new oak gates of very good design. The entrance porch has been entirely removed, and a level entrance is now made into the church. There is also a new gate leading into the churchyard. The whole of the work has been carried out under the direction of Messrs. Haddon. The pulpit, reading-desk, and lectern were executed by Messrs. Vale and Stevens, of Hereford. The rest of the work was executed by Mr. Joseph Turbill, builder, of Church-street, Bromyard.

BRISTOL.—On Monday the foundation stone of the new chapel to be attached to Barstaple's Almshouse at the top of Old Market-street was laid. The dimensions of the new chapel will be 40ft. long by 15ft. wide. The style is Perpendicular, and the chapel will be substantially built of Pennant stone with Bath stone dressings. The total cost is about £1,000. The architects for the new structure are Messrs. Foster and Wood.

CATERHAM.—The Church of the Sacred Heart was opened on August 11th, by Cardinal Manning. The church is cruciform in plan, and consists of a nave, south aisle, north and south transepts, sanctuary, Lady-chapel, and a sacristy, with organ-chamber over. The nave is 15ft. by 21ft., the sanctuary 27ft. by 20ft. The extreme width across the transepts is 50ft. The base of a tower finished as a porch, with a gabled roof, occupies the south-west angle of the building. The seats in the nave will accommodate 200 adults. The aisle and transepts are furnished with chairs, seating another 100. Provision has been made for the addition of a north aisle when such shall become necessary. A presbytery connected with the church by a covered cloister, for the residence of the priest, occupies the upper portion of the site abutting on the main road. The church is built of Reigate stone, Bargate stone, and Box Ground stone. The work is faced externally with Bargate stone from Godalming quarries, and the whole of the quoins, strings, plinths, window-facings, &c., are of Box Ground stone. The style chosen is English Gothic of an early type. Mr. Carruthers, of Reigate, was the contractor for the whole. The architect is Mr. Ingress Bell.

GLOUCESTER. A new Primitive Methodist Chapel has been commenced at Gloucester. The style of the building will be Italian. The chapel will be 62ft. long by 19ft. broad, and the school and class-rooms, which are placed behind, will be 35ft. by 40ft. The height of the chapel wall, within, will be 32ft., and of the school-room wall 28ft., the height of the building at the highest part of the roof being 19ft. Accommodation is afforded on the ground-floor for 384 persons, and in the galleries for 256 more. The school and class-rooms are built for 400 children. The architects are Messrs. Kerridge and Sons, of Wisbech, and the builder, Mr. Wibby, of Gloucester.

KYLL. Christ Church British Schools, Rhyl, were opened on Monday. The design is carried out in brick and terra-cotta. The architect is Mr. C. O. Ellison, of Liverpool and London.

The style is the Domestic Gothic with timber gables, treated with mullions, transoms, &c., in red terra-cotta to match the red brick facing, and with enrichments in terra-cotta, made by Mr. Edwards, of Ruabon. The principal staircase walls are carried up to form a tower at one angle of the building, giving dignity to the whole structure, and grouping well with the several gables, turret, &c., and polished granite blocks built into the centre of diaper panels in various parts of the front. Messrs. Collin and Son, Warrington, are the general contractors. Mr. Hammond has been clerk of works.

SALFORD.—The foundation-stones of Primitive Methodist chapel, Trafford-road, were laid on Saturday last. The chapel measures internally 62ft. by 41ft. 6in. and 53ft. high, being ceiled at collar-beam. The number of sittings provided is 170, seats and all internal fittings will be executed in pitch-pine. The elevations to Trafford-road and West Park-street are faced with stock brick, stone strings and mullions, &c., from Matlock Bath quarries. The total cost will be about £1,700. Mr. Fell, Manchester, is the architect; and Mr. Gerrard Swinton, the contractor.

UPHOLLAND.—It has been decided, at a meeting of parishioners, to restore the ancient church of Upholland, near Wigan. The Earl of Lathom has written two letters on the subject, in one of which he hopes that the necessary funds may be found to restore the fine old church. It had always, he said, puzzled him as to what the original idea of the builders of the church could have been, and if the architect called in, Mr. Champneys, was able to clear up that point, it would help and simplify the work greatly. Mr. Champneys had prepared a report on the state of the edifice, and the repairs necessary to be undertaken. The latter he divides under three heads—first, the substantial repair of the external walls and windows of church and tower; second, the lowering of the floors to the ancient level, the rearrangement of the sittings on the ground-floor, and the introduction of a proper warming apparatus; third, the enlargement of the church eastward, continuation of the arcades and roof, arrangement for organ-chamber, &c.; the total cost being estimated at £3,290. It has been decided to proceed only with sections one and two, which work is estimated to cost £1,600, and a committee has been appointed to carry out the work as speedily as possible.

WINCHESTER.—Several improvements are being carried out on the estate of Lord Northbrook at Stratton, near Winchester. The home-stands on some of the farms have been entirely rebuilt on the most approved principles, and the farmhouses remodelled. Only one pair of cottages has at present been erected, but more are contemplated. The whole of the farm-buildings and cottages are built of bricks and local headed-flints pointed with black mortar; the cottages are covered with plain tiles and the farm-buildings with slates, with the exception of those at the East Stratton Farm, which are covered with Poole's patent tiles. The whole has been carried out by local tradesmen, from the designs and under the superintendence of Messrs. Rayabird and Sons, surveyors and land agents, of Basingstoke, who are also erecting other home-stands on the estates of Lord Templemore, at Preston Candover, near Alresford, and Mr. W. W. B. Black, M.P., of Oakley Hall.

COMPETITIONS.

SWANSEA.—After various meetings the Swansea Town Council have at last decided upon the recipient of the prize offered by them to architects for plans of proposed town improvements. In the first instance, the prize for the best plan was proposed to be divided between "Pro Bono Publico" and "Progress." The latter, however, refused to accept any such proposal, and we now find that "Progress" has been selected. The authors are Messrs. Taylor and Frame, of Cardiff.

The Newbury town council on Tuesday week appointed Messrs. H. O. Baldry and John Austie as engineers to carry out the drainage of the town on the site recommended by Messrs. Law and Chatterton, the arbitrators, who awarded to these engineers the first premium in the recent drainage competition.

ARCHITECTURAL & ARCHÆOLOGICAL SOCIETIES.

LEEDS ARCHITECTURAL SOCIETY.—On Saturday afternoon several members of the above society paid a visit to York, being one of their series of Saturday afternoon excursions, for the purpose of inspecting buildings in progress and also buildings of archaeological interest. Upon arrival in York they proceeded to view the villa residence now in course of erection at Heworth for Mr. J. Bellerby, from designs by Mr. W. G. Penty. In the unavoidable absence of the architect, the members of the society were conducted over the building by Mr. B. Priestley Shires, managing assistant to Mr. Penty, and Mr. F. Osborne, the clerk of works, who explained the various features of the arrangement and design, together with the sanitary arrangements and water supply. After leaving Heworth the party returned to the city and inspected St. Mary's Abbey, Museum and grounds of the Yorkshire Philosophical Society; they also visited the Merchants' Hall, Fossgate, including St. John's Chapel in the basement. After tea, the members visited the exhibition and spent the rest of the evening in viewing the Prince of Wales' collection illustrating the arts of India, and returned to Leeds by the last train, expressing themselves well-pleased with their excursion. It is the intention of the society to pay another visit to York in September next, when their whole time will be devoted to an inspection of the Minster, under the able guidance of Mr. George Bradley.

WELLS ARCHÆOLOGICAL SOCIETY.—On the 11th inst. the above Society, under the direction of the Rev. Prebendary Jones, visited the Manor House of Great Chalfield. Mr. Jones stated that this was one of the finest manor-houses in England, and was built by Sir Thomas Tropenell, about 1435. The Tropenell (now Trapnell) family came into possession of the Great Chalfield Estates by marriage with the Percy family, and possessed many other estates in the adjoining parishes. The lecturer pointed out the beauties of this ancient building, its slender traceried enrichments of the oriel window overlooking the banqueting hall, the "Priest's chamber window," the large carved stone effigies of men in armour, which surmounted the gables at different points of the roof, and he gave it as his opinion that these sculptures were intended for more than mere ornamentation of the elevation, and were, he thought, significant of the official position of the Trapnell family, who, for many generations, held the law-day under Government. In the little church adjoining the manor-house is the chapel built by Sir Thomas Tropenell, which chapel was at one time inclosed by the beautiful carved screen which now incloses the chancel. The walls of this chapel, which are now only whitewashed, were once decorated with frescoes of life-size, representing saints, and it was stated that they were whitewashed by order of a previous vicar, who found that the audience paid more attention to the frescoes than to his sermons. The outlines and some of the colourings are still visible; but it is, we believe, the intention of the present owner of the property, Mr. Fuller, of Neston Park, to restore them. At the conclusion of the proceedings the society visited the ancient Manor House of North Wixall.

ARCHÆOLOGICAL.

CONDITION OF STONEHENGE.—At the meeting of the Wilts Archaeological Society last week, the committee reported that, in conjunction with the secretary of the British Archaeological Association, a representation has been made to the Society of Antiquaries and the Royal Archaeological Institution of Great Britain, calling their attention to the insecure condition of certain stones in the outer circle of Stonehenge, and their imminent danger of falling. At the same time the question of re-erecting the great trilithon, which fell in 1797, and the erection of which had been so often advocated by the archaeologists, was again pressed upon the parent societies. A committee of the Society of Antiquaries, including Sir John Lubbock, had consequently visited Stonehenge last month, and made a careful examination of the stones, the result being that the whole question was to be submitted to a general meeting of the Society of Antiquaries next November. With reference

to the above, Mr. J. J. Cole, F.R.I.B.A., writes: It will perhaps be of interest to the antiquarian societies mentioned that instructions were lately given for a careful examination of the supposed insecure part of the outer circle of Stonehenge and for steps to be taken to avoid an accident. I propose to do so shortly, and also to ascertain the exact degree of inclination of the leaning stone of the central trilithon, and to test it by photographs taken 22 years ago. It is very doubtful whether any movement has taken place within this century. It is useless to urge on the owner of Stonehenge (it is often forgotten that there is an owner), Sir Edmund Antrobus, that the great trilithon which fell in 1797 should be reinstated. The late baronet would not hear of it, neither will the present one. He wrote respecting the outer circle—"To restoration I am distinctly opposed, but this might be considered in the light of preservation, not only of the monument, but of its observers."

PARLIAMENTARY NOTES.

DECORATION OF THE PALACE OF WESTMINSTER.—On Tuesday, on going into Supply, Mr. Schreiber called attention to the unfinished condition of the Central Hall, and moved a resolution calling for its immediate completion in mosaics.—Mr. C. Bentinck energetically opposed the motion, declaring that in our imperfect knowledge of mosaic art such an undertaking must be a failure; and as to the unfinished state of the Central Hall, he pointed out that none of the great monuments of art had been completed in a single age.—Mr. Shaw-Lefevre also opposed the motion, holding that in the present state of mosaic art, and the undecided state of public opinion, it would be very difficult to obtain a vote on the subject. The motion was negatived.

CHIPS.

A new church at Hutton Roof, near Kendal, erected at a cost of £2,500, was opened for worship on Monday week.

Steps are being taken to form a club in Cockermouth. The site is selected, and a plan has been prepared by Mr. W. C. Jennings, architect. The institution is to be confined to a billiard-room, reading-room, &c.

An industrial and fine-art exhibition was opened at Haslemere, Surrey, on Tuesday week. Amongst the local residents who have lent pictures are Mr. Teunynson, Mr. Birket Foster, and Mr. and Mrs. Alma-Tadema.

A new organ was opened at New-road Baptist Chapel, Huddersfield, on Sunday week. Messrs. Jas. Conacher and Sons, of the same town, were the builders.

The parish-church of Wigton was to be reopened by the Bishop of Carlisle yesterday (Thursday). The flagged floors have been replaced by others of wood blocks in nave, and of black and white marble in chancel. New free and open seats, heating-apparatus, and windows have also been put in, and the ceilings and walls have been decorated in colour under the direction of Mr. Leach, of Cambridge.

The laying out and draining of the new sewage-farm at Kidderminster have just been completed under the direction of Mr. Comber, borough surveyor. The contract amounted to £3,500.

Mr. Charles Pugh, inspector of nuisances to the Guildford rural sanitary authority, died very suddenly on Monday week. He was elected to his present office as recently as March last.

The new hotel at Loampt Vale, Lewisham, was opened last week. It has cost about £5,000 for erection, and the builders were Messrs. Crisp and Turner.

The erection of the orchestra at the west end of nave of Worcester Cathedral, for the festival of the Three Choirs, was commenced last week. Messrs. Joseph Wood and Co. are the contractors.

The very small parish-church of Over Denton, Gilsland, was reopened by the Bishop of Carlisle, after restoration and reseating, on Monday.

The foundation-stones of a new Wesleyan school-chapel were laid at North Hykeham on Monday week. Mr. W. Mortimer, of Lincoln, is the architect, and the chapel will seat 200 people, at an estimated cost of £500.

At the International Medical and Sanitary Exhibition, South Kensington, London, which closed last week, Messrs. Robert Boyle and Son, the well-known ventilating engineers, of Glasgow and London, were awarded the "highest prize," for their patent self-acting air-pump ventilators and system of ventilation, this being the only first prize awarded for roof-ventilators.

"To a practical man with a taste for mechanics, and the bump of constructiveness fairly well developed, we can conceive no higher mental treat than a couple of hours spent over the June numbers of that truly marvellous publication the *English Mechanic*. In a hundred and fifty odd pages that make up the bulky mass of letterpress, there is recondite information on almost every conceivable subject, ranging from how to construct a mouse-trap, to the latest method of calculating the phases of Orion."—*The Brightonian*. Price Two pence of all newsmen, or post free 2½d.—31, Tavistock-street, Covent garden, W.C.

TO CORRESPONDENTS.

[We do not hold ourselves responsible for the opinions of our correspondents. The Editor respectfully requests that all communications should be drawn up as briefly as possible, as there are many claimants upon the space allotted to correspondence.]

All letters should be addressed to the EDITOR, 31 TAVISTOCK-STREET, COVENT-GARDEN, W.C.

Cheques and Post-office Orders to be made payable to J. PASSMORE EDWARDS.

ADVERTISEMENT CHARGES.

The charge for advertisements is 6d. per line of eight words (the first line counting as two). No advertisement inserted for less than half-a-crown. Special terms for series of more than six insertions can be ascertained on application to the Publisher.

Front Page Advertisements 2s. per line, and Paragraph Advertisements 1s. per line. No front page or paragraph advertisement inserted for less than 5s.

SITUATIONS.

The charge for advertisements for "Situations Wanted" is ONE SHILLING for TWENTY WORDS, and SIXPENCE for every eight words after. All Situation advertisements must be prepaid.

Advertisements for the current week must reach the office not later than 5 p.m. on Thursday. Front page advertisements and alterations in serial advertisements must reach the office by Tuesday to secure insertion.

TERMS OF SUBSCRIPTIONS.

(Payable in Advance.)

Including two half-yearly double numbers, One Pound per annum (post free) to any part of the United Kingdom; for the United States, £1 6s. 6d. (or 60s. 40c. gold). To France or Belgium, £1 6s. 6d. (or 35s. 30c.). To India (via Brindisi), £1 10s. 10d. To any of the Australian Colonies or New Zealand, to the Cape, the West Indies, Canada, Nova Scotia, or Natal, £1 6s. 6d.

Mr. CHARLES WILSON, of 13 and 15, Laidgate-street, New York City, is authorised to receive American subscriptions at the rate of 6 dollars 40c. per annum.

Mr. R. M. TUTTLE, of Titusville, Penn., U.S.A., is also authorised to receive subscriptions at the same rate. Cases for binding the half-yearly volumes, 2s. each.

NOTICE.

Now Ready.

Vol. XL. Price 12s. A few bound volumes of Vol. XXXIX. may still be had, price Twelve Shillings; all the other volumes are out of print. Most of the back numbers of former volumes are, however, to be had. Subscribers requiring any back numbers to complete vol. just ended should order at once, as many of them soon run out of print.

RECEIVED.—A. H. W.—P. P.—C. Co.—H. and S.—H. L. B.—E. R.—H. W.—G. F. N.—A. and G.—H. B. and Co.—E. M. N.—C. E. J.—G. C.

ONE OF THEM. (1. Firstly incomprehensible. 2. They are elected by the Metropolitan Board of Works from candidates who must have previously passed the examinations held by the Royal Institute of British Architects.)

"BUILDING NEWS" DESIGNING CLUB.

"VERONESE." We shall be glad of the name, address, and age of this contributor on or before the 23rd inst.

Correspondence.

COOPER'S HILL COLLEGE AND THE ROYAL ENGINEERS.

To the Editor of the BUILDING NEWS.

SIR,—I write to deprecate the tone of the letter signed "Jaalam Smith," in your issue of 5th August.

That the first two paragraphs are overstrained to such an extent as to become untrue, every Indian official who reads J. S.'s letter will understand. I see no good whatever in drawing invidious comparisons in the public papers between R.E.'s and C.E.'s—the more so, as I believe there are quite as able men in the corps of Royal Engineers employed in India, as in the same number of civilians; in fact, I may go further, and say that numbers being equal, the majority would be found in the corps of R.E.'s.

Civilians are quite willing and ready to let them have their share of the work and its credit, or otherwise, provided they will allow them a fair proportion of the loaves and fishes.

The real cause of the animus against the corps as a body (not as individuals) is the fact that they are at the head of the administration, and reserve the very few pickings in the service for members of their own body, and are the only channel through whom complaints of civil engineers can reach Government. What civilians

ask for is better retiring-pensions, and that the Civil branches may be administered by civilians, and the military works by military men.

AN INDIAN CIVIL ENGINEER.

August 11th.

VENTILATION OF SOIL-PIPES.

SIR,—Mr. Drury's letter on p. 214, reminds me of a man who has fallen into a bog—the more he struggles the deeper he sinks. He pretends to say I do not know the price of a ventilating trap, nor of the cost of fitting it in, and adds I had omitted to include the "chamber." Now this shows he knows nothing about it, and is merely writing by guess. I have fitted in hundreds of my disconnecting ventilating traps, and built-chambers have only been put in in a few cases, viz., where the traps were deep. These "chambers" are termed "manholes" in Scotland.

Further on in his letter he struggles again, but only sinks overhead, as he tries to show that my remark that a ½ in. outlet, with a large inlet, "helps to prevent accumulation of the sewage-gas at the top of the pipe," is a sufficient reason for him continuing to affirm that the inlet is superfluous, and a ½ in. outlet ventilating-pipe quite enough for any soil-pipe.

Such foolish writing from a man who wishes the public to imagine he knows something, shows how much yet requires to be done for the protection of the public from the ignorant conceit of many tradesmen, let alone any mercenary considerations.—I am, &c.,

W. P. BUCHAN.

SANITARY PLUMBING.

SIR,—I think this will be my last communication in reference to Mr. Hellyer's lectures on sanitary plumbing. I refrained from criticising the last lecture, as some people seemed to think I was too severe and somewhat unjust. I, however, have not had long to wait for an opportunity of proving that my theory was correct and my remarks perfectly just—to wit, the discussion on Monday last at the Society of Arts rooms. Those members of the trade proper, and the professional branches of it—viz., architects, civil engineers, and so-called sanitary engineers who were present, I trust are now convinced that my arguments in favour of the U-trap are quite justified. Some w(H)ould-be plumber defied me to prove my assertions correct as to the superiority of the U over the S-trap in respect of its self-cleaning capacities. There are many in the upper walks of the building trade who have held the same opinions as this before-mentioned incognita; but when, at the discussion, I produced my working model of a "properly-constructed" U-trap and put in a good handful of pebbles, which was readily cleared from the trap by the water, these wise-aeres stood aghast. Now, "Convince a man against his will, he's of the same opinion still," which proved to be the case in this particular instance, as the quibblers said, "Oh, this may answer with pebbles, but how would it do with paper." To settle this point and intended obstacle, I put my pocket handkerchief into the trap, and, like the pebbles, it passed out as would a shot from a gun. As a further test of the efficacy of my U-trap, I filled it with ink and water, and instantly on raising the valve, the ink-and-water was seen to rush into the pail, and actually before any of the water from the supply-trap had time to mix with it. I of course could not show them how it would act with soil, but I venture to think that when, with these three totally different tests, the trap acts with equal rapidity and cleanliness, even sceptics should be convinced, and those of the trade and profession, Mr. H. amongst the number, who have said that rather than have a U-trap they would prefer to dispense with one altogether, have now altered their opinion. One of the assumed demerits of the U-trap was an assertion that it retained more water than the S. Now, in contravention of this assertion, I must tell you that the body of my U-trap was exactly half of that of a 9 in. U-trap that the dip-pipe was 1 ½ in., and that the band was only wide enough to admit the dip. I have also to-day tested, by actual measurement, which trap, U or S, held the most water, and find the U far less, hence it cannot retain (if it retains any) so much foul water as the S. I have also proved, by experiments, that the U does not require any more force of water than the S. Be it, how-

ever, distinctly understood, that these conditions apply only to \odot -traps made after my model. I cannot guarantee a badly-constructed \odot -trap, such as shown at one of the lectures, to do its work properly.

I was extremely pleased to see so numerous an attendance at this discussion, as it undoubtedly served to convince many of at least the junior members of the trade that they have been in error.

In conclusion, I think it only just to say that, although I may have commented somewhat strongly on these lectures, much praise is due to Mr. Hellyer and his condutors of the National Health Society for the great trouble and assiduity they have bestowed on ventilating so important a subject, and think that the thanks of the trade generally are due to those gentlemen. —I am, &c.,

P. J. DAVIES, Hon. Mem. A.S.P.

DESTRUCTION OF THE LANTERN OF WIMBORNE MINSTER, DORSET.

SIR,—All lovers of architecture and antiquity will be sorry to hear that another act of vandalism has been committed at this church.

The unique external Norman arcading, built of a local brown sandstone, is being repaired in white stone, destroying the whole beauty of the tower. I am at a loss to account for the use of Bath stone.

A proof that this brown stone can still be obtained and is used for building purposes, I may mention that G. E. Street, Esq., used it in the building of St. Peter's, Bournemouth, and the church at Spokes-down. —I am, &c.,

MILLS ROBINS.

Hon. Sec. of the Bournemouth Field Club.
5, St. Peter's-terrace, Bournemouth, Aug. 16.

THE SUNDAY SOCIETY.

SIR,—The recent action of the Council of the Working Men's College, in generously placing the college buildings in Great Ormond-street at the disposal of the Sunday Society, has led the Committee to organise a Loan Exhibition of Modern Paintings at that Institution.

This, the twenty-fourth Sunday Art Exhibition opened by the Society, for the instruction and recreation of the people on their leisure day, will consist of paintings which have been contributed by Vice-Presidents and other friends of the Society.

The Exhibition will be open for three Sundays, viz:—August 21st, August 28th, and September 4th. On August 21st, the admission will be by tickets, which may be obtained by all who choose to apply by letter, inclosing stamped and addressed envelope for reply, to the Honorary Secretary, 8, Park-place Villas, W. On August 28th and September 4th the public will be admitted without tickets between the hours of 1 and 6 p.m.

In order that as many as possible may be made aware of the opening of this Exhibition, we beg you to publish this letter.—We are, &c.,

THOMAS BULT, M.P., President.

W. H. CORFIELD, M.A., M.D., Chairman of Committee.

J. W. THOMPSON, Director of the Exhibition.

MARK H. JUDGE, Honorary Secretary.

9, Conduit-street, W., August 18.

The contract for the erection of the first blocks of the intended dwellings for the Manchester and Salford Workmen's Dwellings Company, Limited, has been let to Messrs. Robert Neill and Sons, of Strangeways, at a price slightly under the original estimate of the company's architect, and building operations were commenced on Monday. This experimental venture is only on a small scale, and will consist of 21 ordinary dwellings and one lodging-house. The selected site is a plot of land at Holt Town, in Ancrofts, bounded on three sides by Mellock-street, Weston-street, and Cyrus-street. There will be an open space for playground and drying-ground, having a depth of about 55ft. between the backs of houses. The weekly rent proposed to be charged for each tenement is about 2s. 6d. It is expected that the buildings will be completed and ready for occupation during the present year. The company proposed to adopt the water-closet system, but after consultation with the medical officer of health and city surveyor, have agreed to introduce the pail system.

The London and Middlesborough Archaeological Society held their annual summer meeting at Morton, near Brading, Isle of Wight, on Thursday last week. Messrs. J. E. Price, F.S.A., and F. G. Hilton Price, F.G.S., received the members, and showed the excavations of a series of Roman buildings which they have been carrying forward at Morton for many months past.

Intercommunication.

QUESTIONS.

[6621].—**Competitive Design for Bradford Town-hall.**—Who was the author of the design for the Bradford Exchange, published in the *Building News* of March 24, 1871?—HUGH.

[6622].—**Building Construction.**—Can any of your readers inform me if there is any school in Edinburgh where I can learn the above?—F. P.

[6623].—**Baptistry.**—Will any reader inform me what is the best method of forming a "baptistry" under a Communion floor? The sides are to be faced with white glazed bricks. What thickness of wall should there be, and what should be put behind to render it watertight? How should the floor be formed? Also what depth of water is sufficient for baptismal purposes? A sketch of some good example would greatly oblige.—SIGMA.

[6624].—**Traps.**—Will Hugh McLachlan, G. H. G., or some other kind correspondent, give sketch sections of the various traps \odot , \odot , \odot , and \odot , which I think would be very helpful to many readers now that there is so much said for and against the said traps.—W. K. W.

[6625].—**Drying House.**—Will any reader kindly inform me the best and most economical way of warming a drying house, at the end of a joiner's shop?—Drying-House.

[6626].—**Bakehouse Chimney.**—I have a house which is much incommoded by the smoke from a bakehouse chimney adjoining. Can anyone kindly suggest a remedy for this? Is it possible to make the chimney consume its own smoke?—A. S. S. S. S. S.

[6627].—**Photos.**—Pencil-Sketches.—I should be much obliged if some of your readers would tell me the best way of taking photos. off their mounts; and also the best way of setting pencil sketches.—IGNORAMUS.

[6628].—**Styles of Architecture.**—Will any of your numerous correspondents kindly inform me of the best books I can read on the different styles of architecture.—F. B. P.

[6629].—**Farmsteads.**—I shall be glad to know of one or two examples of the above, not far from London, which may be taken as models. Also of a good book on model farm-buildings.—TERRA.

REPLIES.

[6620].—**Reservoir.**—Thanks to Hugh McLachlan for his reply. I must say the size he recommends for filter bed took my breath away, and I hope he will excuse my asking if a 12in. by 10ft. filter will not filter more water than, say, a 2in. supply pipe from reservoir could possibly take off? Does the total depth of filtering material require to be 4ft.? How is charcoal for the purpose best made or obtained?—L. L. U.

[6629].—**Nave Roof.**—"Student" evidently knows very little about architecture at present. For English Ecclesiastical Gothic he should study the works of Sharpe, Coling, and Brandon. Gwilt's "Encyclopedia of Architecture" (the later editions only) gives much valuable knowledge on the subject, with good articles on proportion referring to other works. There is considerable difference of opinion amongst authorities on the finding of correct proportions, some believing the proportions of the middle ages to have been founded entirely on geometry, others on a correct eye and taste, discarding geometrical rules. Formerly I inclined to the latter opinion, but now to the former, aided by an educated eye and common sense. For French Gothic study the "Dictionnaire de l'Architecture" by M. Viollet le Duc, and for roofs the article "Charpente" in the same. "Student" must I think have also made a mistake as to the pitch of his roof, which is absurd. The scantlings of ridge-pieces depend on the scantlings of the common rafters and the pitch of the roof. In Early English roofs they were omitted, in the Late Gothic roofs they had large scantlings. Now they are seldom more than 1 1/2in. thick and the depth is about that of the common rafter cut across vertically. The scantlings of purlins depend on the distance apart of the trusses and the weight they have to carry; and the scantlings of rafters on their load, length and pitch of roof. To ask for a section of a roof in the "Intercommunication Column" is too much. When inner and outer wall-plates are used they are connected by cross-pieces about 6ft. apart, halved, dovetailed and pinned to them at joints. The common rafters are notched over the outer wall plates, and have short upright pieces or struts studding into the inner plate at foot of rafters over the wall. The principals are in this case set flush on the exterior with the common rafters, the purlins being studded into and secured to them with iron, the principals having extra large scantlings. The moulding of the inner plate depends on the detail of the surrounding work. There is no necessity for moulding when the remainder is also plain. Window heads inside generally have segmental drop-arches. To have the same splay as the jambs is usually a sign of what is commonly known as "barbaric" or "Gothic." The sills of aisle windows will be found varying from 5ft. to 15ft. above the floor line.—HUGH McLACHLAN.

[6630].—**Sashes and Frames. Omission.**—In the fourth line between "argued it" and "though he," &c., read "with regard to small windows."—HUGH McLACHLAN.

[6630].—**London Bridges.**—For Blackfriars railway bridge consult Humber's "Record of Modern Engineering," 1864; for the Thames Embankment, see the same work for 1865.—SIGMA.

[6630].—**Decoration.**—It is always advisable to have ceilings of a light colour, whatever may be that of the walls, since a dark colour depresses a room and apparently decreases the height. The colour may contrast to that on the walls, or be of the same shade according to the style of the decoration and the capability of the artist; both may in their proper places be correct.—HUGH McLACHLAN.

[6631].—**Flow of Water.**—This question cannot be answered unless the absolute length be given. The inclination "1 in 20" is not sufficient. Further, the mode of entry into the pipe should be stated.—C. S.

[6631].—**Flow of Water.**—The question omits to give the "head of water," which is necessary. The number "two" placed in brackets is not sufficiently explanatory, does it refer to the number of the pipes?—HUGH McLACHLAN.

[6632].—**Additions.**—If the clause relating to the referee is as worded in the question, I cannot see how the contractor can ask him to arbitrate. The clause merely names one of the parties in a supposed dispute, the contractor, and does not say therefore between whom the referee is to arbitrate. This being so, I am afraid the contractor must submit to the mercy (?) of the Board, since they do not appear to have given a legal sanction to the additions. I even expect the referee would have to give judgment in favour of the Board, if he could adjudicate.—HUGH McLACHLAN.

[6633].—**Ice-Houses.**—For some time past, in the United States, ice-houses have been protected with silicate cotton, or mineral wool, instead of with sawdust or an air-space, and it has been highly approved of there for that purpose. Silicate cotton is a production from blast-furnace slag, and, in the manufacture of it, the threads are caused to lie in all possible directions with relation to each other, in consequence of which there is no parallelism or common direction in them, so that the air-spaces are angular in shape and microscopic in size. Practical experience with nonconductors of heat or cold has gradually proved that the long-established principles of physics are actually true, viz., that air-confining, or porous bodies are the poorest conductors, and that the passage of heat or cold is retarded in proportion to the volume of air the insulating material holds from circulation. A simple air space of, say 2in., is only effectual as a non-conductor so long as it can be held motionless, but this has been found to be practically impossible. The silicate-cotton is also made in England at the Ties Iron Works, Middlesbrough, and is, I believe, being used for the same purpose here as in America. It should be very inexpensive, and the application is simple, being just the same as if sawdust was being made use of.—S. R.

[6634].—**Coloured Plaster.**—The best way of preparing plaster of a red tint, is to substitute for a portion or the whole of the red brick, ground fine and passed through a sieve used for sifting sand. The proportion will depend both on the colour of the bricks and the depth of the tone required.—HUGH McLACHLAN.

[6635].—**Examination for District Surveyors under Metropolitan Building Act.**—All who wish to be examined should have a good acquaintance with the construction, nature, and strength of building materials, knowledge of the Met. Building Act with Amendments, by-laws and cases on the same tried in the Superior Law Courts. They should also be able to calculate the scantlings and dimensions of structural pieces and prepare working drawings. It is advisable to study, amongst other works, Tarn's "Science of Building," Hurst's "Architectural Surveyor's Handbook" and Woolrych's "Building Act." I believe the examination has become more difficult since I passed.—HUGH McLACHLAN.

[6636].—**Vaulting.**—Draw in pencil by geometry and freehand. French curves may be used when suitable for inking in, but not centres.—HUGH McLACHLAN.

[6637].—**Measuring.**—To find the height of an inaccessible object. Let CD represent the object of which the height is to be found; at any two convenient stations A and B, in the same vertical plane with CD, observe the angles of elevation D A C, D B C, and measure the distance A B. Then, because the exterior angle D B C is equal to the two interior angles E D A, D A B, if D A B be subtracted from D B C, the angle B D A will remain. Now, in the triangle D A B, as sin. D is to sin. A, so is A B to B D;

and in the triangle D B C, as sin. C (a L.) to sin. B, so is B D to C D. Example:—The angle of elevation of a tower, at a station on the same horizontal plane was 48°, and at another station, on a level with the former, and 200 feet farther off in the same direction, the angle of elevation was 26° 45', the height from the eye being 5ft., what was the height of the tower?

$48^\circ - 26^\circ 45' = 21^\circ 15' = A D B.$

To find B D.—

$$\begin{array}{rcl} \text{S. } A D B & = 21^\circ 15' & = 9.5592338 \\ \text{S. } D A B & = 26^\circ 45' & = 9.6331975 \\ \text{S. } A B & = 200 & = 2.3010300 \\ \text{S. } B D & = 218.37 & = 2.3951037 \end{array}$$

To find C D.—

$$\begin{array}{rcl} \text{S. } C & = 90^\circ & = 10 \\ \text{S. } D B C & = 48^\circ & = 9.5710733 \\ \text{S. } B D & = 218.37 & = 2.3951037 \\ \text{S. } C D & = 184.57 & = 2.2661772 \end{array}$$

Height of the Eye = 5'

" " Tower = 189.57 feet, Ans.

—FRED. J. FREEMAN.

[6638].—**Setting Pencil-Sketches.**—No doubt the paper was badly sized at first. Sponge the paper well with alum-water when straining it, if the spotting has not gone too far, you will find this a remedy.—FRED. J. FREEMAN.

[6615].—**Deadening Sound in and Keeping Cool Temporary Buildings.**—There is a fibrous material blown from blast-furnace slag, called slag-wool, or silicate-cotton, which, when properly applied, is an effectual non-conductor of sound, heat and frost. This product is very inexpensive, and can be applied in various ways, but most usually by stuffing it under a thin wooden lagging. It can also be obtained now in the form of "felt," made into flat squares, or in frames, to facilitate its application to vertical surfaces. I believe the slag-wool is being manufactured under patent, on a very large scale, by Messrs. Whisn's, Peace and Co., Middlesbrough. —F. J. K.

[6618].—**Painting and Gilding.**—For the paint you will require white-lead, umber, ochre, driers, linseed-oil, and turpentine. You may put the lead, ochre, umber, and driers, with a little of the oil, into a pot and stir with a stick until smooth. To cause gold leaf to adhere to tissue-paper, you must rub it (the paper) with beeswax, and lay the prepared side of the paper on the gold. In all probability you will be rather clumsy with the gold-leaf, for it requires a little practice to do it properly. —T. PEASAGE.

[6619].—**Carpentering.**—In reply to "Amateur Carpenter," let the mahogany be well seasoned and as free from knots as possible. Use ordinary glue (mixed with water), not too thick; after the easel is glued together, place it in a dry room for a day or two, so as to allow the glue to get hard, afterwards it may be glass-papered over, in order to obtain a smooth face for polishing. —FRED. J. FREEMAN.

[6619].—**Carpentering.**—"Amateur Carpenter" must trust the joiner or cabinetmaker from whom he buys his material as to its being properly seasoned. Any kind of mahogany will suit his purpose. He will find "Honduras" or "Bay" mahogany most easily worked. The person who sells him the wood will also likely be able to supply good glue and willing to show how to prepare it. Good glue is hard in the cake, of a bright amber tint, not too dark, and almost transparent. Break it as small as possible, put into inner pot, and soak with as much cold water as will cover it. If allowed to hang on fire after being heated, it will become too thick, from evaporation of the water. It ought to run freely from the stick with which it is necessary to stir it, and can be tempered to proper consistency by adding boiling-water. Use as hot as possible. —L. L. U.

[6619].—**Carpentering.**—Choose Honduras mahogany, not seasoned too rapidly; cabinetmakers sell it well seasoned. The best sorts of glue are hard, transparent, of a clear amber colour, swell very much in water, but do not dissolve, and they return to their former size when dry. Break the glue into small pieces, soak it in as much cold water as will cover it for several hours. Melt this in a double glue-pot, the outer pot fill with water, simmer for an hour or two, and add hot-water to make it liquid enough to look rosy when it runs from the brush: when the glue is done with, put more hot-water to make it thin, and cover the pot to keep out dust, &c., do not have too large a pot, freshly-made glue is best. "Amateur Carpenter" should get a mate who knows how to make a studio easel easily, to show him. I presume he is very amateur if he does not know how to melt glue, and to use the glue-pot. —W. JACKSON, JUN.

[6620].—**Building.**—In reply to "Owenz," I submit the following investigation of his question of the last issue. I have endeavoured to make it as simple as possible, so that it may be easy to follow, and show how the formula was arrived at. In what follows these particulars will be adhered to:—The wall to be standing on a horizontal surface, on which it will not slide; *a*, rectangle in any cross-section; *l*, its length; *h*, its height; *t*, its thickness; *w*, its weight per cubic foot; *G*, its centre of gravity; *P*, the overturning pressure to be found, acting horizontally at the centre of top of wall. We will first find *P* by the graphic mode (see figure) thus: Draw

section of wall to a convenient scale, find its centre of gravity, *G* (at the crossing of the diagonals). When the wall is just balanced on *A*, three forces, weight of wall, *P*, and their resultant, or reaction, must all pass through one point, the resultant also passing through *A*. Therefore, draw *EF* vertically through *G*, to cut top of wall in *F*, where *P* acts, then join *AF*; *EF*, *FD*, and *AF*, are the positions and directions of the three forces mentioned above, one of which we particularly desire to know. Mark off, by any convenient scale, along *FE*, *FK* to represent the weight of the wall; from *K* draw *KL* horizontally and *HL* vertically from *L*. Then *FHLK* is the parallelogram of the forces acting on the wall, and keeping it in equilibrium about *A*; *KL*, or *FH*, measured to the scale of forces will give *P*. The resultant *FL* has been made to pass through *A*; if it passed outside of *A* it would overturn the wall. To cause this, *P* must be very slightly increased. To find a formula, or rule,

for finding *P* we may take the moments of the weight of the wall, and the pressure *P*, both about the edge *A* of the wall, thus:

$$\text{Weight of wall} = lhtw.$$

$$\text{Moment of wall} = lhtw \times \frac{l}{2} = \frac{lh^2tw}{2}$$

$$\text{Moment of } P = Ph.$$

$$\text{When the wall is just balanced about } A \quad \frac{lh^2tw}{2} = Ph.$$

$$\text{Therefore } P = \frac{lh^2w}{2h}.$$

$$\text{Or in words, Pressure} =$$

$$\text{Length} \times \text{height} \times \text{thickness squared} \times \text{weight per c. f.} \\ \text{Twice the height.}$$

The pressure *P* to be most effective should be equally distributed along the length of the wall. It would be interesting to find the safe amount for *P*; the angle through which the wall must be tilted before it begins to fall; and other matters, but they lie outside the limit of this reply. —A. R. F. TAEW.

LEGAL INTELLIGENCE.

RAILWAY PRECINCTS AND LOCAL BY-LAWS.—The case of Wimbledon Local Board v. Ely came again before the police magistrate (Mr. Paget) at Wandsworth on Saturday week. The local board brought the test action to try the right of Mr. Ely to erect an office on railway property (at Wimbledon Railway Station) without first submitting plans to the board as the urban sanitary authority. For the defence it was contended that the fact of the building being erected on railway land exempted the builder from the ordinary law. Mr. Paget, however, decided in favour of the board, and inflicted a small fine on Mr. Ely, remarking at the same time that the action ought to have been taken earlier.

IMPORTANT TO BRICKMAKERS.—About 300 workmen at Sittingbourne, who at Michaelmas, 1880, had signed contracts to make bricks at a definite and specified price during the 1881 season, recently demanded an advance of 3d. upon every 1,000 bricks made, and upon being informed that the contract rate of payment would be adhered to they struck. A week later, however, they all returned to work, except a young man named William Dunk and three or four others, in the employ of Messrs. Smeed and Co., who went away and obtained employment elsewhere. Breaches of contract by brickmakers have hitherto been dealt with under the Employers and Servants Act; but in this instance the case was made a more serious matter, and brought before the magistrates under section 5 of the Conspiracy and Property Protection Act, 1875. The prosecutor sought to show that the defendant maliciously broke his contract, having reasonable cause to believe that the probable consequence of his so doing, either alone or in combination with others, would be to expose valuable property to destruction or serious injury. The Bench, however, held that the contracts, being for piece-work, did not come within the meaning of the Act. They also considered there was no intention on the part of the defendant to injure his employers' property. They, therefore, dismissed the summonses, but said they should have no objection to state a case upon the point.

IN RE C. B. WALKER (Before Mr. Registrar Murray).—The debtor, who had presented a petition on Wednesday for liquidation, is described as of Ranelagh-road, Willesden, and of Harrow and Barking, builder. His debts, secured and unsecured, are estimated at £56,000, and assets £2,000. Upon the application of Mr. Doria, his honour appointed Mr. W. Williams, accountant, to the office of receiver of the estate, and granted an injunction restraining various actions.

WATER SUPPLY AND SANITARY MATTERS.

BRIGHTON.—MR. ROBERT RAWLINSON, C.B., ON SEWER VENTILATION.—The Town Council of Brighton, having applied to the Local Government Board for permission to borrow the sum of £2,100 for works of sewerage and street improvements, Mr. Robert Rawlinson, C.B., C.E., held an inquiry at the town-hall, on Thursday, the 11th inst. During the inquiry the inspector opened an exhaustive discussion on the general question of sewer ventilation. The borough surveyor (Mr. Lockwood) had stated that in the formation of the new Bear-road in the north of the town he intended to trap the various gullies laid down. Mr. Rawlinson recommended that this should not be done. The late borough surveyor of Leeds, Mr. Morant, had untrapped every gully in that large borough, and the consequence of converting the gullies into so many ventilators was that the mortality was greatly reduced. He admitted sentimental objections often prevented this being done satisfactorily; but he argued that though an unpleasant odour might be experienced in the street, it was so diluted as to be practically harmless, while the thousandth part of that vapour infiltrated into a house, through the drain-pipe, was absolutely deadly. An imperfect system of ventilation would naturally give rise to

objections because it unfairly saddled the disadvantages on to one particular individual; but the greater means of ventilation the less likelihood there was of inconvenience. Having no personal interest in Brighton, Mr. Rawlinson said he felt in a position to offer independent advice according to the best of his ability. To Brighton it was absolutely essential that it should have a clean bill of health, and it was a town possessing splendid opportunities for ventilation by reason of its gradients, and the local authorities should get all the relief they could from sewer gas at the higher points. He knew from long experience that although it was not pleasing to have an opening in the street near one's house, the complaint was an imaginary grievance. Persons looked at a ventilating grating, and swore through thick and thin that it injured them, whereas experience had taught him that it did nothing of the kind, for when foul gas was liberated into the open air, the teeth of the mischief were drawn. Mr. Alderman Lester asked as to the efficacy of certain patented plans of sewer ventilation, to which Mr. Rawlinson replied that he must not be expected to express an opinion one way or the other with regard to some of the patents in vogue. The question, after all, was a very simple one, and the remedy equally simple; but he must warn people that by connecting ventilating shafts with their drains inside the house they ran great risk of attracting sewer-gas through their premises.

STATUES, MEMORIALS, &c.

ST. ANDREW'S.—Mr. Hutchison, R.S.A., has just completed a piece of sculpture, which is to be placed as a memorial to a deceased lady in the Cathedral grounds of St. Andrew's. Angelic in form, the figure stands with folded wings, which arch slightly above the head. It is 7ft. in height, the cross about 4ft., the whole composition being sculptured from a single block of Sicilian marble. A base and plinth of the same material, on which the figure will rest, will raise the height of the memorial to 9ft.

JOAN OF ARC.—The committee for the erection of a monument to Jeanne d'Arc, at Domrémy, has just entrusted the execution of the group in marble and bronze, for which a large sum of money has been subscribed. This group will comprise four statues—those of Jeanne d'Arc, and of St. Michel, St. Catherine, and St. Marguerite. The figure of Jeanne d'Arc will be the only one in marble, the other celestial personages being represented in bronze. This monumental group will be placed at a few yards from the parish-church of Domrémy, under the clock-tower of a new chapel constructed on the spot occupied formerly by the oratory to which tradition has attached the name of the Maid of Orleans.

BYRON'S GRAVE.—In the floor of the chancel of the parish-church of Hucknall Torkard, Nottinghamshire, and immediately over the coffin containing Lord Byron's remains, last week was fixed a slab of marble set for the purpose by the Byron Memorial Committee. The marble is of the kind known as "Rosso Antico," of a dull red colour, and was obtained from a quarry which, until recently, had not been worked for a very long period. The slab, which is a little more than 2ft. square, is a portion of the large block presented to the committee by the King of Greece as a pedestal for the Byron statue in Hamilton-gardens, Hyde-park.

CHIPS.

On Saturday the memorial-stone was laid of Oatlands U.P. Church, Glasgow, which has been designed by Mr. J. B. Wilson, architect, of that city. The church, which is in the Early Gothic style, will, it is estimated, cost £3,500. It will accommodate about 800 sitters, and will be provided with halls and class-rooms.

A correspondent of the *Echo* says that on visiting Hampton Court a day or two ago, he was surprised to find that the small, though highly interesting, collection of arms and armour is simply going to decay for want of a little care and attention. "The steel Cromwellian head-pieces and horse-armour are positively red with rust."

The committee of the national memorial to Lord Beaconsfield report that they have received £1,789, and £405 are promised. They have selected Signor M. Raggi to execute the statue, which, in bronze, with its pedestal, is to be completed in fifteen months for the sum of £3,150. The statue is to be placed in Parliament-square.

The parish of South Hornsey, which has a population of 14,000, is to have a town hall. The site is in the Milton-road, a thoroughfare lying between and running parallel with the Albion-road, Stoke Newington, and the Newington-road. The buildings will be of brick and Portland stone, and will cost £8,000.

Our Office Table.

AN exhibition of art productions by residents in the county of Devon was opened, in the Albert Memorial Museum, Exeter, on Monday, by the Mayor. The exhibits number about 700, and include oil-paintings, water-colours, decorative designs, carvings, models, stained-glass, photographs, lace, and embroidery. Pottery, too, will be well represented; the manufacturers of the ware at Torquay, Watcombe, Fremington, and Barnstaple having furnished specimens. Teignmouth and Torquay have especially entered into the movement. Prizes, to the amount probably of £100, will be awarded. The Exhibition will remain open for a month.

AN apparatus is said to have been invented by Herr Meydenbauer, Inspector of Buildings at Marburg, which promises to be of some value in architectural drawing. The invention appears to consist in a device for reconstructing the perspective representation given by ordinary photographs, so as to exhibit the various parts in their true geometrical relation. This is not a very difficult operation, even without special apparatus, and most students of perspective have probably amused themselves by finding the two vanishing points of an architectural photograph, and retracing the perspective processes until the two geometrical elevations were regained. The studies so made have some value, and will do more to instruct young architects in the proportions of a style than the study of those sketch-books whose authors generally care much more for effective drawing than exact representation of what they see. Herr Meydenbauer's method, if it shortens the labour of transforming converging into parallel lines, may meet with extended application.

AN American journal says: The use of elm-wood for various purposes is claiming the attention of manufacturers. The elm marketed is known as the "gray elm." Elm of any kind is rightly designated when it is called "tough," and tough it is, after the manner of tough leather. Its grain is not straight and easily separated, like oak or some other woods, but is interwoven, gnarled, knotty, and tough, as any one may learn who attempts to cut it. The elm in use is the water elm, found in high places. Until lately it was let alone and considered useless; but any farmer, where elms grow, knows the value of elm. When a new axe-handle is wanted, he does not buy the cheery and cross-grained helve manufactured to wear out speedily, but makes one by his own handiwork from an elm limb. Such a helve will outlast a dozen of the machinery-cut kind. For all kinds of farming implements elm is particularly desirable, as well as for wheel stock and any contrivance that requires strength.

AN interesting report has just been issued by Dr. Littlejohn and Mr. A. Rutherford, who, at the instance of the Scotch Board of Supervision, conducted an inquiry into the causes of a mysterious epidemic which broke out in Aberdeen in the end of March, over 300 people being affected thereby. It was satisfactorily established that in every well-authenticated instance of the occurrence of the epidemic the family affected was supplied with milk from the Old Mill Reformatory dairy; and from analysis of the water supply of the steading and samples of milk taken at the time of the epidemic it was found that both contained organisms. These were believed to result from foul cisterns; but as the samples of milk taken from the cows were found pure, how the milk was afterwards contaminated by the water the Commissioners were unable to discover. The Commissioners insist on the most perfect sanitary conditions being observed in all dairies. Pathological experiments on the lower animals had been made by experts, which showed the dangerous character of the milk contamination.

"It is of no use," writes Mr. H. W. Brewer to the *Saturday*, "attempting to bring such a serious question as the destruction of St. Alban's before the British Archaeological Association. I was present at their meeting on June 1st, but their time was too much occupied with an old dead beetle and the origin of the mermaid, to attend to the historic and religious monuments of their country! A piece of broken glass, a few beads, and a rusty nail interested them far more than a noble minster. I had no idea that archaeology was such a childish study,

or could at least be reduced to such a low level. It is evident to my mind that most of the members present did not care one straw about St. Alban's Abbey, and that several of them rather looked upon Sir E. Beckett's 'restoration' as an improvement. It is not wise, perhaps, to talk of serious things to children while they have their *toys on the table*; and I saw at once that it would be useless to speak about St. Alban's to these grown-up children, while they had their bits of broken tiles, dead beetles, beads, and jimcracks lying before them."

By the destruction of the new Bohemian (Czech) Theatre at Prague, the country has lost one of its greatest architectural ornaments; and the drama, as performed in that particular Slavonic tongue, has received a blow from which it can hardly ever recover. It was only after many years of exertion that the Czechs succeeded in obtaining the means for erecting this beautiful edifice. It was nearly ten years in building, and was only opened on the occasion of the *fetes* in honour of the marriage of the Crown Prince Rudolph and the Princess Stephanie, in the middle of May last. The theatre had, therefore, not been opened three months, and now, owing to the grossest carelessness and negligence that cannot be too severely condemned, the entire edifice has been laid in ashes. In an investigation which has been already commenced as to the origin of the conflagration, several of the witnesses examined said that they first saw flames near a workman who was occupied in fixing a lightning-conductor under the roof of the building. The calamity is simply traceable to the culpable negligence of the artisans occupied with a small furnace on the roof.

DR. SCHLIEHMANN'S new work, "Orcho-menos," has been issued by Messrs. Brockhaus, of Leipzig. In it he describes his last journey from Athens to Orchomenos, Orchomenos itself, and Copais. "There are but three towns," writes Dr. Schliemann in the preface, "which Homer has designated as 'abounding in gold,'—viz., Troy, Mycenae, and Orchomenos. The treasures I have brought to the light of day from the ruins of the first two abundantly justify the epithet of the Greek poet. In Orchomenos I did not, it is true, find any golden stores, but the treasure-chamber and the thalamos, with its elaborately carved stone ceiling, which I excavated, are mute evidences that there, too, great riches were once heaped up, and that Homer's description were equally true as regards that town."

IN the art and home handicraft sections of the Hotwells Industrial Exhibition, Bristol, is a design by Mr. Wm. Edward Hill, hon. secretary of the British and Clifton Junior Architects' Society, for artistic, healthy, and economical homes for the working classes, which has been awarded a second-class prize and certificate. These houses are designed to be erected in concrete, but may be adapted to any building material. The plan embodies good accommodation, and the sanitary arrangements are entirely separate from the domestic part. The front elevation of the house is simple, and it is claimed that the general arrangement of these dwellings would be such as to make the tenant take a pride in his home and in its cleanliness, and thus help to improve the general tone of social life amongst the working classes. The designer estimates the cost of erecting these houses in concrete at about £150 the pair.

WHILE the work of piercing the Channel Tunnel is being steadily proceeded with in England, it is followed up no less eagerly in France. The French engineer has lately had an interview with the President of the Republic, who, after having studied the plans and listened to the explanations of the engineer, promised that the matter should receive the serious attention of the Government. Another great engineering project—viz., that of inundating the desert of Sahara, has just received a rude shock from Dr. Lenz, who has just returned from African travel. He characterises the Mackenzie scheme as chimerical, in consideration of the fact that the western side of the desert is considerably above the level of the sea. In his opinion, the only practical scheme for opening up the country is by the construction of railroads; but an undertaking of this description would be both difficult and extremely expensive.

THE Water-gate of York House, it seems, according to a correspondent of the *Times*, is under nobody's care at present. In the year 1751 an Act of Parliament was granted to enable the proprietors of houses in York-buildings to make and levy a rate on themselves sufficient to answer the expense of repairing the terrace-walk and water-gate, and this was effectually done at that time; but about thirty years since, the trustees having all died, the collection of the rate for maintenance was abandoned, and the terrace and gate became neglected. In 1863, a report descriptive of designs for the Thames Embankment was presented to the Metropolitan Board of Works by Mr. T. W. Bazalgette, in which were the following observations:—"Between Westminster and Hungerford bridges would be landing-stairs for smaller craft, and here it is proposed to introduce the beautiful water-gate now situate at the end of Buckingham-street, and erected after a design by Inigo Jones." This scheme was, however, not carried out, in consequence of opposition by one of the adjoining owners. He, however, has given way, and is now willing that the Metropolitan Board of Works should raise it out of the mud cast around it.

CHIPS.

Amongst those who have died from injuries received in the recent Blackburn railway accident were Mr. John Swift, builder and contractor, of Bradford, and his wife.

The Lambeth vestry on Thursday week elected Mr. Firth Groves, of Brixton-road, as medical officer of health and inspector of nuisances for the parish. There were 39 candidates for the appointment.

A public meeting was held at the town hall, Brentford, on Friday evening, to consider the advisability of establishing schools of science and art in the town, but after the scheme had been explained, and its advantages pointed out, no one would move a resolution approving of the proposal, and the meeting broke up in confusion.

The memorial-stone of an Odd Fellows' hall for Netley was laid on Thursday week. The plans have been prepared by Sergeant Rowe, R.E., and Mr. Musslewhite, of Hound, has taken the contract for erection.

A mission-hall is about to be erected in the Grove, Crouch-end, Hornsey, from the plans and designs of Mr. John Farrar.

The tower of St. Lawrence's Church, Ipswich, has recently showed traces of weakness, and, a few weeks since, some masonry fell from the west face, breaking shop-windows on the opposite side of Dial-lane. Mr. Frederick Barnes, F.R.I.B.A., of Hatton-court, Tavern-street, Ipswich, was consulted, and scaffolding having been erected under his advice by Messrs. Pells and Sons, builders, it has been found that the condition of the steeple is worse than had been expected. A vestry meeting was held last week to consider the matter, when Mr. Barnes reported that, after consulting other architects, he was still of opinion that it could be repaired. The vicar suggested that the tower should be removed, and the nave extended over its site, and the meeting was adjourned to allow of consideration of the question whether rebuilding or demolition shall take place. The tower, although plain, is a well-proportioned fifteenth-century structure, some 93ft. in height, and standing, as it does, in the centre of the town, forms one of a group of steeples which contribute much to the picturesqueness of Ipswich as seen from a distance. The faces of the tower, originally of brick and rubble masonry, are covered with cement, now fast peeling off; at the angles are four stone urns, incongruous memorials of churchwardenism of two generations since; and, above the well-carved oaken west door, a huge and unpunctual clock projects frying-pan-wise over the adjacent narrow lane, opposite the end of which, within a score paces of the tower, is the well-known Ancient House. It would be a matter for regret if so distinctive a feature of Old Ipswich as St. Lawrence's steeple were removed for any less urgent cause than the public safety.

The new town-hall, at Hastings, illustrated in the *BUILDING NEWS* for Nov. 9, 1880, will be opened on Wednesday, September 7th. It has been built from the designs of Mr. Henry Ward, under the superintendence of Mr. Wm. Andrews, the borough surveyor, and is Gothic in style. The external walls are of a local blue stone, with Bath-stone dressings. Messrs. D. C. Jones and Co., of Gloucester, are the contractors.

An organ, built at a cost of £400, by Mr. G. Hawkins, was opened at Newton Abbot Church on Tuesday week.

THE BUILDING NEWS.

LONDON, FRIDAY, AUGUST 26, 1881.

THE BATTLE OF THE TRAPS.

ONE of the questions which the recent lectures by Mr. Hellyer on Plumbing have reopened, concerns the relative claims of the siphon and the \cup -trap. The full reports we have given of those lectures, and especially of the discussion last week (see page 227 ante) have enabled our readers to draw their own conclusions respecting the arguments brought forward by the various speakers, for the retention or disuse of either of these safeguards of our drains. We have long doubted whether these ingenious expedients have the real worth plumbers of the old school credited them with, and since recent revelations and the discussions upon them which have taken place, we are surprised to find plumbers still quarrelling over the merits of certain forms of traps.

Traps have undergone every conceivable modification in form since their introduction, and there are still in the market objectionable types. A good water-trap is one which will for the longest period insure an unbroken water-seal and which every flush makes clean. There should be no abrupt change in the direction of the flow, no sharp edges, and very quick bends are found less desirable than flutter ones. A water-seal, one authority says, ought not to be less than $\frac{3}{4}$ in., nor more than 1 $\frac{1}{2}$ in., and 1 in. is the usual depth of closet-trap seals. Generally easy bends are better than deep traps, and more likely to allow of an easy passage of matter through them. But the advocates of both the two principal types of trap, the \cup and the \mathcal{S} , have assumed a certain amount of ignorance on the part of the public and the profession, and the battle has been waged almost exclusively by patentees.

It is generally admitted that all traps are liable to "waving-out" or siphonage if not ventilated, and the remarks of Mr. E. aptage, of Margate, corroborate the opinion generally received, that both the \mathcal{S} and \cup -traps require ventilation, though the latter and the \mathcal{V} hold their seals more tenaciously. With regard to self-cleansing qualities, Mr. P. J. Davies has, to a certain extent, disproved the alleged non-cleansing property of the \cup -trap by the experiment he made with pebbles, though the form he exhibited and that generally used are somewhat different. It has been established, however, by general consent, that the siphon-trap, despite its demerits in the matter of siphonage, is the more scientific form for self-cleansing, and the profession will learn, probably with some astonishment, that even its predecessor can be made to perform the function quite as well. There are, however, \cup -traps and \mathcal{S} -traps, and it would be of some importance if the profession would decide what form and proportion of this trap are safe. Mr. Davies has, by his graphical method of striking out the form of trap he recommends, endeavoured to solve this problem, and we refer our readers to his demonstration.

The two main considerations on which the advocates of the rival traps base their claims are, first, with regard to siphonage, and second, to cleanliness. No one doubts that the \cup -trap is more secure as regards the first condition: the very form of the water-seal renders "waving-out" less easy; but we venture to think the best test of the second quality is the experience gained of two kinds in actual use. The majority of those who took part in the discussion were practical men, and they have probably seen

what many who have had any experience of sanitary work have witnessed—a gradual fouling up of the \cup -trap, owing to the flow of water not coming in contact with the upper part of the trap. As might be expected, also, the square corners become filled with gas, and promotes corrosion of the lead, a point mentioned by Mr. Buchan.

The quantity of water held by a \cup -trap is undoubtedly greater than the quantity held by a siphon, and this is a point which, to our minds, would have much to do with the cleanliness of the trap. Mr. Davies has, it appears, tested this point, and finds that less water was contained in *his* form of \cup -trap than in the siphon, or than in the 9 in. \cup -trap; but of course the question of form and size has much to do with the matter, as well as with the force of water required to cleanse a trap efficiently. Practical points of connection with the soil-pipe have operated in favour of retaining the old-fashioned \cup -trap; but we are sure that of the two forms it must gradually give way either to a modification, as proposed by Mr. Davies, or to the ventilated siphon arrangement.

The remedy for "unsiphoning" a trap is to introduce an inlet at the highest point of the bend, and connect it with a soil or air-pipe, so that when a falling column of water induces suction behind it, the vacuum may be instantly filled up and the water-seal spared. With proper care, therefore, in ventilating arrangements, the trap may be made independent of the risk of siphonage and a check of secondary importance established, while the ingenuity of inventors might be more profitably turned to the object of perfecting the flow and self-cleansing qualities of these appliances. We have already hinted that their efficiency depends much on the direction of the inlet and outlet, or, in other words, the contour of the trap. The \cup -traps still retain much of their old objectionable form, though some patentees have endeavoured to make them more perfect by doing away with corners which obstruct solid matters and produce fouling at those parts. Mr. Davies's improvements and Mr. Hellyer's patent \mathcal{V} -dip or "anti- \cup -trap" are steps in the right direction. There are no corners to become clogged up, and the water is made to exercise a scouring action upon the bottom. The seal is 1 $\frac{1}{2}$ in. The discussion which has taken place lately in our own pages on the relative merits of the two rival forms of trap, has at least indicated a desire on the part of the advocates of both kinds to perfect them, while it has also shown that with proper precautions each kind of trap can be made efficient. Even the much-praised siphon is not always constructed with due care to its efficiency. We have seen, indeed, sudden bends and deep water-seals which would make it difficult for anything to pass through. In others the fault has been an easy bend and a quick fall, the effect of which is that the momentum of the flush would drive out the water entirely, and unseat the trap. Unfortunately, however, these sanitary controversies savour too much of the *odium theologium* spirit. A blind partisanship sees nothing but perfection in a certain appliance, and any desire for improvement is often frustrated by the attempt to force the competing claims of the other side.

GABLES AND THEIR TREATMENT.

THERE are many people—those who design houses and those who live in them—who think that in an artistic house we cannot have too much of a good thing. Take, for example, the Gothic cottage *ornée* as we see it in books of designs. Every front or elevation rejoices in a gable, often two or more; and as for dormer windows, they are crowded into every blank space, unmindful of the

confusion of gutters and valleys, and of the pocket of the proprietor. According to the exponents of Gothic of this kind, a multiplicity of gables was thought to characterise the style, and these were placed without apparent motive, in every position available. We had gabled porches, gabled bays, gabled projections and dormers, as if to signalise more emphatically the departure from flat roofs and parapets. It not only complicated the roof, but rendered necessary an addition to the ironmonger's bill for stack-pipes and ornamental heads of cast iron; while the plumber derived his share of profit from a roof which demanded all the skill of the lead-worker to make it perfect. Followers of the Late Domestic architecture now in vogue, cannot be said to be more discreet in learning where to place their gables. We occasionally see two or three jostling one another in a small front, as if they were all contending for supremacy, or so various in their composition that we doubt whether the architect really has left out something in one or two of them, or had exhausted all his resources upon the other. If a plan or elevation turns out poorly, gables are the only means present to the mind of such an architect of improving the grouping, and they certainly add to the picturesqueness of a house. Introduce a gable or two, and the elevation is made; it is easily done and makes the house presentable, at least on paper. Now the gable naturally arose from the necessity of finishing the ends of a span roof; it was a necessity springing out of plan and roofing. All the most telling examples of gable architecture to be found in Warwickshire, Worcestershire, and other counties have arisen in this way, and the best examples of the structural gable will be found in 15th and 16th century buildings. In these instances we find them to be the ends of independent roofs joining one another at right angles, or intersecting, and seldom mere gables stuck on in front of a roof for the sake of appearance. In later examples it became a more adventitious feature as we notice in many of the half-timbered houses of Kent—at Chiddingstone, for instance, where we have three timbered gables, with their ridges, meeting a high-pitched roof. In this house, however, the two extreme gables are wide, and project over the bays below with carved brackets, and were constructed to give additional rooms in the upper story. The smaller centre gable crowns a projecting room or landing carried by wooden posts in front of the entrance, thus forming an open porch. At Meer Hall (illustrated last week) a series of gables are placed between the more prominent gables of the wings, all stopping against a roof at the ridge-level. We rather desire, however, to point to earlier work, of Domestic Gothic character, for types of the feature. In these the commonest plans have one block crossed by a single wing, or by two wings, each gabled at the ends. Arrangements of this sort sometimes show a balanced arrangement; in others cases they do not. In the Manor House at Pershore Abbey (see illustration in Mr. W. Niven's etching, reproduced by us last week) the gables are honestly and simply grouped; they are, in fact, all structural, and we seldom find more than three gables in one front. To take another extreme instance, Morton Hall, Cheshire, we find low-pitched gables in exuberance over the bays, and their roofs made to intersect round the octagon-sided windows; but we feel they have been overdone, in spite of the charming carved detail and mouldings.

Generalising from a few of the most agreeable examples of gable treatment, we may point out a few principles which have been followed with the most pleasing artistic results. It will generally be found that plan has been mainly consulted in the distribution of gables, or, to make our

meaning clearer, the gable has been the outgrowth of a projecting part of a building, or has been introduced for the sake of simplifying the roofing. Doubtless the artistic value of the feature was always present, but it was never the leading motive in the best examples. They appear to grow out of the building naturally, without an effort. Sometimes, as we have seen, an additional room in the roof suggested a gable to obtain height. Another readily-understood principle is that as roofs generally were placed with their axes at right angles, gables appeared on at least two adjacent fronts, and a gable was generally, therefore, seen in conjunction with a roof slope. It almost follows, from these considerations, that the number of gables in a building should bear some proportion to its size, and that a balanced arrangement is only suited for an important front. In a small villa one prominent gable may dominate and be placed at one end, or divide one wing from a more receding portion. If another gable appears it is better to be made a subordinate one. Two gables of the same or similar size near or close together seldom group well, and a central and two small gables have a rather formal appearance only appropriate to large houses or buildings of public character. Aston Hall has three on one front, but they are well grouped. One often meets with a house with a central tower over the porch and a gable on each side; scarcely any arrangement is less pleasing, the tower and the gables cut up the roof-line and quarrel for mastery, and it does not mend matters to make one on a different plane to the other. There is in short an art of grouping which only can be learned by careful observation combined with artistic instincts, and it will be found the ablest masters of the art are content with taking the plan and working out their roof with the least intention of making a display of their gables. On the other hand, we find all sorts of restless fidgety attempts made by some designers, who are never satisfied till they have crowded as many gables as they can in the frontage. These are generally of various heights and levels, cutting awkwardly against eaves and hips, and rising to different heights instead of trying to preserve a common ridge-level. Not content with these irregularities, they vary the faces of the gables. Some are brick, others tile-hung, one is half-timbered, and another is a mixture of timbering and tile-work. The stranger seeks in vain for a *raison d'être*, but he sees none, and probably if he examined the interior he would still be left to ponder over this medley of fancies of the modern builder. Wherever we go we find the gable mania to be again in the ascendant, though this time without the spikes and finials. If economy were the motive one might not wonder; but we should like to know in how many instances the gabled roof has been adopted for the sake of giving a room or two in the roof, and it ought to be remembered, a phalanx of gables is more costly than the addition of another story covered in a plain, unostentatious manner.

It must not be thought we are raising any objection to an architectural feature which has given so much charm and poetry to Continental buildings. We are only protesting against the fashion of multiplying the feature in small houses. We cannot even go so far as to admire the architecture of such streets as that in Landshut, Bavaria, referred to by Mr. J. J. Stevenson, where the houses of most varied and picturesque detail are all gabled, and we can fully understand, despite their diversity and quaintness, that the gutters between the houses do not contribute to their comfort. No artist can deny the picturesqueness of the gabled houses seen in the Low Countries, Belgium, or Brussels; but this kind of architecture has

its limit, and it will be acknowledged that, apart from the interest of the gable giving an opportunity for timbering, parget-work, and carving, the beauty and value of the gable is enhanced when it is used sparingly, and with an endeavour to give it a functional rather than a superficial character.

PLASTER-WORK.

THE subject of decorative plastering has recently taxed the knowledge of architects, and details of the methods used by the old plasterers are eagerly sought after. It is, however, not a difficult matter. The methods of making "coarse stuff" and "fine stuff," "gauge stuff," the selenitic cement mortar, Keene's and Parian cements, rough-casting, and other processes are well known, and the modern plasterer can probably turn out as good plaster-work if he likes as the old plasterer in the days of the Stuarts. Under the modern contract system, the plasterer has become a vastly different artificer to the workman who executed the panel and enriched ceilings of the Elizabethan and Stuart periods. He is now seldom an artist, though he can model any amount of enrichments of the stock patterns. The history of the trade is one intimately related with the progress of art in this country for the last three hundred years. Not to speak of the ancient Romans, who were noted for their mortar and plaster incrustations, the Medieval architects never had that distaste for plastering their interiors which some have imagined. Everyone who has carefully examined any of the old monastic buildings and churches, will have found abundant evidence to the contrary. A close examination of the walls will disclose fragments of plaster in either thin or thick coats, and the rubble walls of many of our ruined abbeys have pieces still adhering to the stonework, often coloured. One writer alludes to a thin layer of plaster at Little Braxted church, Essex, a building of Transitional Norman character, on the rubble walls; and Mr. Buckler, in his "Churches of Essex," mentions some plastered brick windows. Many of the groined vaults of the old abbeys, as at Netley, were plastered, and the cathedral of Rochester shows plastering between the wooden ribs. We are tempted to mention examples of Medieval plastering, but we pass on to notice the parget-work of the 16th and following centuries, which has lately found imitators.

This kind of plastering was used externally, and instances of it occur in Essex, Norfolk, Suffolk, Sussex, Hampshire, and other counties where timbered houses are found. Ornamental parget-work was generally employed between the studs of timber houses in the Tudor and Stuart times. The ornament was often of figures and foliage raised or in relief, as we find in some old buildings at Ipswich, Maidstone, &c., and more frequently of patterns incised or sunk in the plaster, such as may be seen in a few old houses in Newark, Shrewsbury, Coventry, and in many places in Essex. We have found little information respecting the composition of such plaster-work; but there is no doubt that the devices were either cut, modelled, or impressed upon the plaster when wet. The *modus operandi* was doubtless the following:—A board of the size of the panel or ornament was obtained, in which were stuck pins in the shape of the device, and this was pressed on the wet plaster, and completed by hand.

Many of these timbered houses are filled in with rough-cast, a plaster in which sharp stones are mixed, or these are thrown forcibly from a trowel against the wet plaster. We find on many of the old manor-houses dating from Tudor times, "rough cast," and this appears to have been made of lime, hair, and coarse sand, with small pebbles intermixed. Glass

and brick fragments are often found in lieu of the pebbles. This kind of plaster was very durable, and has lasted to our day in tolerable preservation. Many recent attempts have been made to imitate the rough-cast panelwork of the period to which we have been referring, though we question if the modern work will stand so long. Rye-straw has been found in specimens of old plastering, and there is no doubt fibre of some kind was mixed in it.

The ceilings of the 16th, 17th, and 18th centuries have long been the theme of admiration, and in spite of our *papier maché* and *carton pierre*, few modern ceilings equal those of earlier date. The Italian designs, introduced in the Stuart period, no doubt brought with them Italian stuccoists who were equal to the occasion. The Adams, Chambers, and Wyatt led the way for the light, tasteful relief-ceilings we have lately been reproducing in our buildings, and the acme of ceiling-decoration appears to have been reached by these later artists. It must not be overlooked that these examples were worked chiefly by hand. Casting in plaster-moulds followed, and a revolution quickly set in. Casts of original ornaments and figures superseded hand-carving, and plastering became a mere mechanical art. Even in this art of casting in plaster changes have crept in which have deteriorated the quality of the enrichments. The "jelly mould," as every plasterer knows, does not produce such sharp relief as plaster or lead moulds did, which were in several portions, though we have seen many ceilings executed in *carton pierre* which, for sharpness and relief, equal hand-work. The worst of stamped and moulded work is that a spiritless kind of repetition is apt to be followed, and we find very many of the newly-built houses with parquet work overdone with commonplace devices. It is perhaps to be regretted our architects do not follow the plaster-work found in Italy and Spain, and Mr. Street, writing on the subject in his "Gothic Architecture in Spain," alludes to the tracery patterns of Late Gothic, which are repeated to produce a diaper in the Alcazar at Segovia, and other buildings. All the Moorish decorative work was executed in plaster of fine quality, but cut and carved, so there is, as the same authority remarks, endless variety. We have another kind of decorative plaster "*sgraffito*," an instance of which will be seen in the paneling at the National School for Music, near the Albert Hall, at South Kensington; but we are inclined to think the experiment will not be soon followed. This kind of incised ornamentation is exceedingly obtrusive, and we are disposed to prefer the less decided relief of the plaster itself to such glaring panel treatment. The subject is one intimately bound up with the future of cement concrete.

THE SUNDAY SOCIETY'S LOAN EXHIBITION.

AS intimated in our columns last week, the committee of the Sunday Society have organised a loan exhibition of modern paintings in the rooms of the Working Men's College, Great Ormond-street, which have been generously placed at the disposal of the society. This makes the twenty-fourth Sunday Art Exhibition opened by the Society for the working classes, and it is intended to keep the exhibition open free for the following two Sundays—namely, the 28th of August and the 4th of September. Last Sunday admission was by tickets obtained by those who cared to avail themselves of them, and on the two following Sundays the public will be admitted without tickets between the hours of one and six p.m. The present loan exhibition, through the exertion of its committee and the director, is worthy of the object in view, and the pictures, which com-

se oil and water-colour paintings and monochrome drawings, have been collected from a variety of sources. We recognise many of them as having lately graced the walls of the Grosvenor Gallery, the Royal Academy, the Suffolk-street and Dudley Galleries.

Glancing round the commodious rooms placed at the service of the Society, we find paintings by H. H. Cauty, Phil. R. Morris, A.R.A., P. Naitel, C. Marshall, S. Hill, L. P. Smythe, Alf. W. Williams, Rooke, W. Holman Hunt, Frank Holl. R.A., Walter Crane, Professor W. B. Richmond, F. Smallfield, A. Goodwin, Clara Montalba, &c. "The Last of a Ruined Home," by H. H. Cauty, is a touching incident painted in the artist's best style. The figures are introduced with much dramatic power: the brick wall and iron gates about being closed, the entrance to the once comfortable house and grounds, tell tale to the disconsolate group seated on the roadside, which the painter has forcibly presented. A birch grove, by J. H. Bell, is tenderly painted and truthful, and the portraits of J. M. Rooke are masterpieces of vigorous execution. The admirer of a more pleasing kind will find nothing to recall the enjoyment of real life in L. P. Smythe's scene, a girl reposing meditatively on a grassy margin — "Down by the River" — the grass and water of which are very feelingly rendered, and with the finished execution of the artist. Very cleverly and tenderly-painted is a small object by P. R. Morris, "Homeward Bound," two girls with a younger brother passing a common with a bundle of wood. The low key of colour and the handling exhibit masterly study; and just below it is a small piece, in low tone, vigorously tinted, of foliage and landscape (No. 27). No. 3 (by L. P. Smythe) is vigorous in the tures, and "A Sermon on the Simples," by A. Goodwin, is a dexterous study of pine scenery and atmosphere. We notice, in the same room, "Slyhead Pass" (No. 12), a large painting of a rocky valley, by A. W. Hunt, in which the artist has represented, with much power, one of the grandest scenes of scenery in Cumberland. Characteristic and evincing much power, is the head of a "Swabian Peasant Woman," by Charlotte J. Weeks. "Near Munich" (22), by Swengauer, is a pleasing sunset; and other bright sunny landscape, painted by Walter S. Lloyd, called "A Quiet Nook," draws attention for the thoroughly English sentiment and truthful handling of the trees and pool. We may also glance at landscapes by G. Howard (16, 17), "Autumn on the Surrey Hills," by C. P. Slocombe; "A Woman of Jerusalem," by W. Holman Hunt — a study in chalk, "Sands of Calais," by W. L. Wyllie; and a vigorously-executed portrait by Mr. John Collier of that artist's wife (15), to show that variety of subjects has been obtained. Of large works we find two decorative pieces, painted by Walter Crane, which we have seen before at the Grosvenor. One is in a low key of colour, but executed in a luminous and half-hazy style, not altogether useless in the drawing of the figures. The "Fate of Proserpina," by the same artist, is a more solidly-painted subject, and thoroughly pre-Raphaelite in manner and treatment. The large study of "Still Life," by Otto Scholderer (46), is bold and masterly in grouping and tone, and another picture showing "Luther on his Way to the Diet of Worms," by Teschendorfer, will be gazed on with interest. But the greatest modern work of oil exhibited is hung in the lecture-room, and is entitled "Behold! the Hidegroom Cometh," by Professor W. B. Richmond, a work which occupied the place of honour in the last Grosvenor Gallery exhibition, and upon the merits of which we

have previously spoken. This large painting is well hung as regards light, and the grace and beauty of some of the virgins, and the skilfully-managed atmosphere of the piece will be scanned again with probably more interest than they were in the Grosvenor.

In another room is a collection of water-colour drawings. We note in this part of the exhibition two Hampshire views by R. A. K. Marshall—one of Hurstbourne Park, and the other a village, both in the valley of the Test; they are highly finished. "Waterside Weeds" (103) is pretty. We must notice also one or two charming poems in colour we have seen elsewhere, by Clara Montalba; one, a View under Cannon-street Bridge. (No. 112), by W. Hall, is a skilfully manipulated drawing; P. Naitel sends "The Playing Fields at Eton" (131); No. 111, "Venetian Boats," by H. Darval is clever in grouping and colour; and we mark No. 115, by Frank Murray, and "Puck and the Fairy," by Ernest Wilson, besides two clever drawings by Alf. W. Williams, highly finished and truthful in their patient elaboration of foreground and mountain. Some Welsh scenery by C. P. Slocombe; landscapes by C. Marshall; "Views from Rome," by Walter Crane; and studies of heads by F. Smallfield are among the works contributed. Portraits are never very instructive; but a few are to be seen in the museum-room, by L. Dickenson, of some merit. Those of the visitors who care to study the work of deceased masters of the English water-colour school will be interested in a very valuable representative collection, embracing works by T. Gainsborough, David Cox, Copley Fielding, Peter de Wint, J. Varley, J. M. W. Turner, J. S. Cotman, T. F. Wheatley, E. Dayes, J. Flaxman, A. Penley, the younger Pugin, J. Holland, and others. These paintings and drawings have been willingly contributed by the artists or owners of them, without the expression of a hostile opinion, showing that a liberal spirit is beginning to manifest itself on the Sunday question. Such exhibitions as these must tend more to instruct than to do harm, and we hope many of our artisans and workmen may be induced to spend their Sunday leisure here, rather than in more objectionable haunts.

THE WATER QUESTION.—XV.

INNER SLOPE OF AN EARTHEN EMBANKMENT.

THE safety of a reservoir embankment does not depend upon one thing only, as upon the perfection of the puddling, but equally upon several others, chief amongst which is the consolidation of that part of the bank which lies within the puddle wall, and into which, therefore, water would penetrate if not prevented, and this prevention depends chiefly upon the thickness of the layers of earth with which the embankment is raised. Thin layers are always desirable: but the maximum thickness which may be allowed depends on the material and the means by which it is deposited in the bank. A heavy and dry material may be deposited in thicker layers than one of less specific weight, with equal effect in both cases in forming a solid bank. The thickness allowable has been variously stated at 6in., 12in., 15in., and 2ft. Where the chief consideration has been the urgent progress of the work to meet a demand for water, as was the case when, in order to meet the demands of the approaching summer, the embankment of the reservoir, on the Dale Dike at Bradfield, was urged forward by the Sheffield Waterworks Company, in the early part of the year 1864, and which burst in March of that year; the earth forming the bank on each side of the puddle wall has been tipped from rail-waggons at a height of 5 or 6ft., and more; but few waterworks engineers would sanction that,

except for the outer part of the bank, and even for that part it is too high, because the large and small rock are not evenly mixed; the large lumps roll to the bottom of the tip and form a layer there of themselves; the finer stuff laying together upon the coarse layers; whereas, to prevent slipping, which is one great object of all the precautions, the large and the small should be as evenly mixed as is practicable, except in those parts where material is purposely selected to be deposited, fine in one part and large in another, for different purposes. If the material tipped into the bank were all stone, the rolling of the large lumps into a separate layer would be less objectionable; and, indeed, with stone for the material it might even be an advantage that the layers should be so arranged, for the one would drain the other, and the bank, as a whole, would retain less water than it otherwise would do; but with other materials, such as shale, blue bind, or, indeed, any material but stone, the same object would not be effected.

In making the inner part of the embankment of a reservoir the object is to make it as compact as possible to prevent the water reaching the puddle wall, and, therefore, the material should be small and clayey; but in the outer part of the bank dryness and stability are the chief objects, for which larger and harder material is more suitable. The inner slope of an embankment is usually made flatter than the outer slope, as 3 to 1 inside and 2 to 1 outside, for the inner part of the bank is more liable to slip than the outer. When the water-level in the reservoir is reduced, if the inner part of the bank has been penetrated by water and become partially saturated, slips are more likely to take place, and the flatter slope meets this tendency; but outside, with dry materials, 2 to 1 is as good a slope as 3 to 1 inside. As a further precaution against slipping it is desirable to keep up the outer parts, next the slopes, higher than the inner parts next the puddle wall.

If rail-waggons be used at all, it is desirable that they should be of small size, to hold, say, not more than one cubic yard; but if waggons be allowed, there will always be a tendency on the part of everyone concerned to make the tips high and the layers thick, to avoid much shifting of the rails if possible, and especially by the use of side-tip waggons; but if the instruments for carrying the stuff into the bank be confined to barrows, dobbin-carts, and common one-horse carts, it does away with this tendency in a great measure. When large waggons are advocated, it is asserted that the greater weight and the heavier rails compensate for the greater height of the tips, and so an equally good consolidation of the earth is effected. The degree of consolidation, by the weight of the instrument by which the earth is transported, admits of proof. In respect of any one square yard near the middle of the bank, lengthwise, the consolidation of the one immediately preceding it may be shown as follows:—Premising that whatever the thickness of the layers, variation in weight of the different kinds of earth, or time of construction, the degree of consolidation by the weight of the carrying instrument must be in the inverse ratio of the weight carried each journey, the weight of the instrument being reckoned twice going full and returning empty.

Thus, if w = weight of earth carried, and W = weight of instrument carrying it.

$$\frac{W}{w} = \text{degree of consolidation.}$$

The actual weights of different kinds of earth vary much; but, for the purposes of comparison, an average weight of 2,600lb. per cubic yard may be taken, or 96lb. per cubic foot, and the effect of the carrying instrument may be stated thus:—

meaning clearer, the gable has been the outgrowth of a projecting part of a building, or has been introduced for the sake of simplifying the roofing. Doubtless the artistic value of the feature was always present, but it was never the leading motive in the best examples. They appear to grow out of the building naturally, without an effort. Sometimes, as we have seen, an additional room in the roof suggested a gable to obtain height. Another readily-understood principle is that as roofs generally were placed with their axes at right angles, gables appeared on at least two adjacent fronts, and a gable was generally, therefore, seen in conjunction with a roof slope. It almost follows, from these considerations, that the number of gables in a building should bear some proportion to its size, and that a balanced arrangement is only suited for an important front. In a small villa one prominent gable may dominate and be placed at one end, or divide one wing from a more receding portion. If another gable appears it is better to be made a subordinate one. Two gables of the same or similar size near or close together seldom group well, and a central and two small gables have a rather formal appearance only appropriate to large houses or buildings of public character. Aston Hall has three on one front, but they are well grouped. One often meets with a house with a central tower over the porch and a gable on each side; scarcely any arrangement is less pleasing, the tower and the gables cut up the roof-line and quarrel for mastery, and it does not mend matters to make one on a different plane to the other. There is in short an art of grouping which only can be learned by careful observation combined with artistic instincts, and it will be found the ablest masters of the art are content with taking the plan and working out their roof with the least intention of making a display of their gables. On the other hand, we find all sorts of restless fidgety attempts made by some designers, who are never satisfied till they have crowded as many gables as they can in the frontage. These are generally of various heights and levels, cutting awkwardly against eaves and hips, and rising to different heights instead of trying to preserve a common ridge-level. Not content with these irregularities, they vary the faces of the gables. Some are brick, others tile-hung, one is half-timbered, and another is a mixture of timbering and tile-work. The stranger seeks in vain for a *raison d'être*, but he sees none, and probably if he examined the interior he would still be left to ponder over this medley of fancies of the modern builder. Wherever we go we find the gable mania to be again in the ascendant, though this time without the spikes and finials. If economy were the motive one might not wonder; but we should like to know in how many instances the gabled roof has been adopted for the sake of giving a room or two in the roof, and it ought to be remembered, a phalanx of gables is more costly than the addition of another story covered in a plain, unostentatious manner.

It must not be thought we are raising any objection to an architectural feature which has given so much charm and poetry to Continental buildings. We are only protesting against the fashion of multiplying the feature in small houses. We cannot even go so far as to admire the architecture of such streets as that in Landsbut, Bavaria, referred to by Mr. J. J. Stevenson, where the houses of most varied and picturesque detail are all gabled, and we can fully understand, despite their diversity and quaintness, that the gutters between the houses do not contribute to their comfort. No artist can deny the picturesqueness of the gabled houses seen in the Low Countries, Belgium, or Brussels; but this kind of architecture has

its limit, and it will be acknowledged that, apart from the interest of the gable in giving an opportunity for timbering, parget-work, and carving, the beauty and value of the gable is enhanced when it is used sparingly, and with an endeavour to give it a functional rather than a superficial character.

PLASTER-WORK.

THE subject of decorative plastering has recently taxed the knowledge of architects, and details of the methods used by the old plasterers are eagerly sought after. It is, however, not a difficult matter. The methods of making "coarse stuff" and "fine stuff," "gange stuff," the selenitic cement mortar, Keene's and Parian cements, rough-casting, and other processes are well known, and the modern plasterer can probably turn out as good plaster-work if he likes as the old plasterer in the days of the Stuarts. Under the modern contract system, the plasterer has become a vastly different artificer to the workman who executed the panel and enriched ceilings of the Elizabethan and Stuart periods. He is now seldom an artist, though he can model any amount of enrichments of the stock patterns. The history of the trade is one intimately related with the progress of art in this country for the last three hundred years. Not to speak of the ancient Romans, who were noted for their mortar and plaster incrustations, the Medieval architects never had that distaste for plastering their interiors which some have imagined. Everyone who has carefully examined any of the old monastic buildings and churches, will have found abundant evidence to the contrary. A close examination of the walls will disclose fragments of plaster in either thin or thick coats, and the rubble walls of many of our ruined abbeys have pieces still adhering to the stonework, often coloured. One writer alludes to a thin layer of plaster at Little Braxted church, Essex, a building of Transitional Norman character, on the rubble walls; and Mr. Buckler, in his "Churches of Essex," mentions some plastered brick windows. Many of the groined vaults of the old abbeys, as at Netley, were plastered, and the cathedral of Rochester shows plastering between the wooden ribs. We are tempted to mention examples of Medieval plastering, but we pass on to notice the parget-work of the 16th and following centuries, which has lately found imitators.

This kind of plastering was used externally, and instances of it occur in Essex, Norfolk, Suffolk, Sussex, Hampshire, and other counties where timbered houses are found. Ornamental parget-work was generally employed between the studs of timber houses in the Tudor and Stuart times. The ornament was often of figures and foliage raised or in relief, as we find in some old buildings at Ipswich, Maidstone, &c., and more frequently of patterns incised or sunk in the plaster, such as may be seen in a few old houses in Newark, Shrewsbury, Coventry, and in many places in Essex. We have found little information respecting the composition of such plaster-work; but there is no doubt that the devices were either cut, modelled, or impressed upon the plaster when wet. The *modus operandi* was doubtless the following:—A board of the size of the panel or ornament was obtained, in which were stuck pins in the shape of the device, and this was pressed on the wet plaster, and completed by hand.

Many of these timbered houses are filled in with rough-cast, a plaster in which sharp stones are mixed, or these are thrown forcibly from a trowel against the wet plaster. We find on many of the old manor-houses dating from Tudor times, "rough cast," and this appears to have been made of lime, hair, and coarse sand, with small pebbles intermixed. Glass

and brick fragments are often found in lieu of the pebbles. This kind of plaster was very durable, and has lasted to our day in tolerable preservation. Many recent attempts have been made to imitate the rough-cast panelwork of the period to which we have been referring, though we question if the modern work will stand so long. Rye-straw has been found in specimens of old plastering, and there is no doubt fibre of some kind was mixed in it.

The ceilings of the 16th, 17th, and 18th centuries have long been the theme of admiration, and in spite of our *papier maché* and *carton pierre*, few modern ceilings equal those of earlier date. The Italian designs, introduced in the Stuart period, no doubt brought with them Italian stuccoists who were equal to the occasion. The Adams, Chambers, and Wyatt led the way for the light, tasteful relief-ceilings we have lately been reproducing in our buildings, and the acme of ceiling-decoration appears to have been reached by these later artists. It must not be overlooked that these examples were worked chiefly by hand. Casting in plaster-moulds followed, and a revolution quickly set in. Casts of original ornaments and figures superseded hand-carving, and plastering became a mere mechanical art. Even in this art of casting in plaster changes have crept in which have deteriorated the quality of the enrichments. The "jelly mould," as every plasterer knows, does not produce such sharp relief as plaster or lead moulds did, which were in several portions, though we have seen many ceilings executed in *carton pierre* which, for sharpness and relief, equal hand-work. The worst of stamped and moulded work is that a spiritless kind of repetition is apt to be followed, and we find very many of the newly-built houses with parquet work overdone with commonplace devices. It is perhaps to be regretted our architects do not follow the plaster-work found in Italy and Spain, and Mr. Street, writing on the subject in his "Gothic Architecture in Spain," alludes to the tracery patterns of Late Gothic, which are repeated to produce a diaper in the Alcazar at Segovia, and other buildings. All the Moorish decorative work was executed in plaster of fine quality, but cut and carved, so there is, as the same authority remarks, endless variety. We have another kind of decorative plaster "*sgraffito*," an instance of which will be seen in the paneling at the National School for Music, near the Albert Hall, at South Kensington; but we are inclined to think the experiment will not be soon followed. This kind of incised ornamentation is exceedingly obtrusive, and we are disposed to prefer the less decided relief of the plaster itself to such glaring panel treatment. The subject is one intimately bound up with the future of cement concrete.

THE SUNDAY SOCIETY'S LOAN EXHIBITION.

AS intimated in our columns last week, the committee of the Sunday Society have organised a loan exhibition of modern paintings in the rooms of the Working Men's College, Great Ormond-street, which have been generously placed at the disposal of the society. This makes the twenty-fourth Sunday Art Exhibition opened by the Society for the working classes, and it is intended to keep the exhibition open free for the following two Sundays—namely, the 28th of August and the 4th of September. Last Sunday admission was by tickets obtained by those who cared to avail themselves of them, and on the two following Sundays the public will be admitted without tickets between the hours of one and six p.m. The present loan exhibition, through the exertion of its committee and the director, is worthy of the object in view, and the pictures, which com-

prise oil and water-colour paintings and monochrome drawings, have been collected from a variety of sources. We recognise many of them as having lately graced the walls of the Grosvenor Gallery, the Royal Academy, the Suffolk-street and Dudley Galleries.

Glancing round the commodious rooms placed at the service of the Society, we find oil-paintings by H. H. Cauty, Phil. R. Morris, A.R.A., P. Naftel, C. Marshall, J. S. Hill, L. P. Smythe, Alf. W. Williams, J. Rooke, W. Holman Hunt, Frank Holl, A.R.A., Walter Crane, Professor W. B. Richmond, F. Smallfield, A. Goodwin, Clara Montalba, &c. "The Last of a Ruined Home," by H. H. Cauty, is a touching incident painted in the artist's best style. The figures are introduced with much dramatic power: the brick wall and iron gates about being closed, the entrance to the once comfortable house and grounds, tell a tale to the disconsolate group seated on the roadside, which the painter has forcibly represented. A birch grove, by J. H. Snell, is tenderly painted and truthful, and the portraits of J. M. Rooke are masterpieces of vigorous execution. The admirer of *genre* of a more pleasing kind will find something to recall the enjoyment of rural life in L. P. Smythe's scene, a girl reposing meditatively on a grassy margin — "Down by the River" — the grass and water of which are very feelingly rendered, and with the finished execution of the artist. Very cleverly and tenderly-painted is a small subject by P. R. Morris, "Homeward Bound," two girls with a younger brother crossing a common with a bundle of wood. The low key of colour and the handling exhibit masterly study; and just below it is a small piece, in low tone, vigorously painted, of foliage and landscape (No. 27). No. 3 (by L. P. Smythe) is vigorous in the figures, and "A Sermon on the Simphon," by A. Goodwin, is a dexterous study of Alpine scenery and atmosphere. We notice, in the same room, "Slyhead Pass" (No. 12), a large painting of a rocky valley, by A. W. Hunt, in which the artist has represented, with much power, one of the grandest pieces of scenery in Cumberland. Characteristic and evincing much power, is the head of a "Swabian Peasant Woman," by Charlotte J. Weeks. "Near Munich" (22), by Swengauer, is a pleasing sunset; and another bright sunny landscape, painted by Walter S. Lloyd, called "A Quiet Nook," draws attention for the thoroughly English sentiment and truthful handling of the trees and pool. We may also glance at landscapes by G. Howard (16, 17), "Autumn on the Surrey Hills," by C. P. Slocombe; "A Woman of Jerusalem," by Mr. Holman Hunt — a study in chalk, "Sands at Calais," by W. L. Wyllie; and a vigorously-executed portrait by Mr. John Collier of that artist's wife (18), to show that variety of subjects has been obtained.

Of large works we find two decorative pieces, painted by Walter Crane, which we have seen before at the Grosvenor. One is in a low key of colour, but executed in a luminous and half-hazy style, not altogether faultless in the drawing of the figures. The "Fate of Proserpina," by the same artist, is a more solidly-painted subject, and thoroughly pre-Raphaellesque in manner and treatment. The large study of "Still Life," by Otto Scholderer (46), is bold and masterly in grouping and tone, and another picture showing "Luther on his Way to the Diet of Worms," by Teschendorffer, will be gazed on with interest. But the greatest modern work of oil exhibited is hung in the Lecture-room, and is entitled "Behold! the Bridegroom Cometh," by Professor W. B. Richmond, a work which occupied the place of honour in the last Grosvenor Gallery exhibition, and upon the merits of which we

have previously spoken. This large painting is well hung as regards light, and the grace and beauty of some of the virgins, and the skilfully-managed atmosphere of the piece will be scanned again with probably more interest than they were in the Grosvenor.

In another room is a collection of water-colour drawings. We note in this part of the exhibition two Hampshire views by R. A. K. Marshall — one of Hurstbourne Park, and the other a village, both in the valley of the Test; they are highly finished. "Waterside Weeds" (103) is pretty. We must notice also one or two charming poems in colour we have seen elsewhere, by Clara Montalba; one, a View under Cannon-street Bridge. (No. 112), by W. Hall, is a skilfully manipulated drawing; P. Naftel sends "The Playing Fields at Eton" (131); No. 111, "Venetian Boats," by H. Darval is clever in grouping and colour; and we mark No. 115, by Frank Murray, and "Puck and the Fairy," by Ernest Wilson, besides two clever drawings by Alf. W. Williams, highly finished and truthful in their patient elaboration of foreground and mountain. Some Welsh scenery by C. P. Slocombe; landscapes by C. Marshall; "Views from Rome," by Walter Crane; and studies of heads by F. Smallfield are among the works contributed. Portraits are never very instructive; but a few are to be seen in the museum-room, by L. Dickenson, of some merit. Those of the visitors who care to study the work of deceased masters of the English water-colour school will be interested in a very valuable representative collection, embracing works by T. Gainsborough, David Cox, Copley Fielding, Peter de Wint, J. Varley, J. M. W. Turner, J. S. Cotman, T. F. Wheatley, E. Dayes, J. Flaxman, A. Penley, the younger Pugin, J. Holland, and others. These paintings and drawings have been willingly contributed by the artists or owners of them, without the expression of a hostile opinion, showing that a liberal spirit is beginning to manifest itself on the Sunday question. Such exhibitions as these must tend more to instruct than to do harm, and we hope many of our artisans and workmen may be induced to spend their Sunday leisure here, rather than in more objectionable haunts.

THE WATER QUESTION.—XV.

INNER SLOPE OF AN EARTHEN EMBANKMENT.

THE safety of a reservoir embankment does not depend upon one thing only, as upon the perfection of the puddling, but equally upon several others, chief amongst which is the consolidation of that part of the bank which lies within the puddle wall, and into which, therefore, water would penetrate if not prevented, and this prevention depends chiefly upon the thickness of the layers of earth with which the embankment is raised. Thin layers are always desirable; but the maximum thickness which may be allowed depends on the material and the means by which it is deposited in the bank. A heavy and dry material may be deposited in thicker layers than one of less specific weight, with equal effect in both cases in forming a solid bank. The thickness allowable has been variously stated at 6in., 12in., 18in., and 2ft. Where the chief consideration has been the urgent progress of the work to meet a demand for water, as was the case when, in order to meet the demands of the approaching summer, the embankment of the reservoir, on the Dale Dike at Bradfield, was urged forward by the Sheffield Waterworks Company, in the early part of the year 1864, and which burst in March of that year; the earth forming the bank on each side of the puddle wall has been tipped from rail-waggons at a height of 5 or 6ft., and more; but few waterworks engineers would sanction that,

except for the outer part of the bank, and even for that part it is too high, because the large and small rock are not evenly mixed; the large lumps roll to the bottom of the tip and form a layer there of themselves; the finer stuff laying together upon the coarse layers; whereas, to prevent slipping, which is one great object of all the precautions, the large and the small should be as evenly mixed as is practicable, except in those parts where material is purposely selected to be deposited, fine in one part and large in another, for different purposes. If the material tipped into the bank were all stone, the rolling of the large lumps into a separate layer would be less objectionable; and, indeed, with stone for the material it might even be an advantage that the layers should be so arranged, for the one would drain the other, and the bank, as a whole, would retain less water than it otherwise would do; but with other materials, such as shale, blue bind, or, indeed, any material but stone, the same object would not be effected.

In making the inner part of the embankment of a reservoir the object is to make it as compact as possible to prevent the water reaching the puddle wall, and, therefore, the material should be small and clayey; but in the outer part of the bank dryness and stability are the chief objects, for which larger and harder material is more suitable. The inner slope of an embankment is usually made flatter than the outer slope, as 3 to 1 inside and 2 to 1 outside, for the inner part of the bank is more liable to slip than the outer. When the water-level in the reservoir is reduced, if the inner part of the bank has been penetrated by water and become partially saturated, slips are more likely to take place, and the flatter slope meets this tendency; but outside, with dry materials, 2 to 1 is as good a slope as 3 to 1 inside. As a further precaution against slipping it is desirable to keep up the outer parts, next the slopes, higher than the inner parts next the puddle wall.

If rail-waggons be used at all, it is desirable that they should be of small size, to hold, say, not more than one cubic yard; but if waggons be allowed, there will always be a tendency on the part of everyone concerned to make the tips high and the layers thick, to avoid much shifting of the rails if possible, and especially by the use of side-tip waggons; but if the instruments for carrying the stuff into the bank be confined to barrows, dobbin-carts, and common one-horse carts, it does away with this tendency in a great measure. When large waggons are advocated, it is asserted that the greater weight and the heavier rails compensate for the greater height of the tips, and so an equally good consolidation of the earth is effected. The degree of consolidation, by the weight of the instrument by which the earth is transported, admits of proof. In respect of any one square yard near the middle of the bank, lengthwise, the consolidation of the one immediately preceding it may be shown as follows:—Premising that whatever the thickness of the layers, variation in weight of the different kinds of earth, or time of construction, the degree of consolidation by the weight of the carrying instrument must be in the inverse ratio of the weight carried each journey, the weight of the instrument being reckoned twice going full and returning empty.

Thus, if w = weight of earth carried, and W = weight of instrument carrying it,

$$\frac{W}{w} = \text{degree of consolidation.}$$

The actual weights of different kinds of earth vary much; but, for the purposes of comparison, an average weight of 2,600lb. per cubic yard may be taken, or 96lb. per cubic foot, and the effect of the carrying instrument may be stated thus:—

One indeed is a splendid example of Gothic, the other is a very poor one, and so the comparison is hardly fair. But still I would ask the younger members of the association, when they visit Pershore, after inspecting the Abbey Church, to go also into the other parish-church close to it, and to believe, what we older ones can assure them of, that many a parish-church they now enter with artistic pleasure, if not with antiquarian interest, was but little better, say, in 1810, than that which seems now so strange. And since these questions of restoration or preservation chiefly refer to our churches, it is impossible to forget that they are not merely monuments of antiquity serving for the delight of the archaeologists: they are buildings intended for use—for a most important, a most sacred use. If they are now less interesting as monuments, they are much more beautiful, more suited to the purposes of devotion as churches. There is no reason why both objects should not be attained to. It is usually from ignorance or carelessness—it may be of the architect, it may be of the builder, it may be of the restoration committee—that the old and interesting features have disappeared, when the important work of restoration has been carried out. The Cathedral of Worcester is perhaps one of the finest examples of restoration you can anywhere meet with. I had almost said of over-restoration, but had I done so I might have been misunderstood. The interior of the Cathedral is one of the finest I am acquainted with; I may say, the very finest, considering its size. From the old engravings and from what I am told, it must be far finer now than it was before the work was begun. The outside of much of the building is terribly new, and no doubt much less picturesque than it was. But in an archaeological point of view, what has been lost? The whole of the outside stone had largely perished, in the beginning of the 18th century, from the ravages of the weather upon its surface. Mouldings and other delicate features could scarcely be traced. Then came the hand, not of the restorer, but of the men who wished to make it neat and new and tidy. They pared down the moulding lines, and reduced each stringcourse to what they look upon as a more perfect condition; they put on the top of the pinnacles "neat" spires, formed like that of St. Andrew's Church, in Worcester city; they repaired the tracery of the east window, according to their notions of what we should now call Late Gothic. Was all this worth keeping? Is it not far better that our east window, which we see so much from the interior, our pinnacles outside, our drip-mouldings and stringcourses should be renewed to something like their original Early English character, even though this involved some newness of appearance for a few years? The walls were dangerous. Unsightly modern buttresses supported them. Nothing short of rebuilding would suffice. The internal stonework was replaced, stone by stone, as far as possible. The outside stone was going again as it had gone before. Was it not wise to substitute for it a casing which would stand the weather, and put the Early English Cathedral of Worcester again before our eyes? So far, then, I think the restoration of Worcester Cathedral was wisely and well carried out. Still, in some respects, I think the restorers went too far. The large lancet windows of the eastern portion of the building had, in some cases, been subdivided by a mullion, and their heads filled with tracery at a later period of Gothic art. These portions, not being original, were removed at the restoration; and I regret it, both as they were part of the history of the building in the period of our greatest architects, and also because it seems to me that we have really lost some beauty by this change. I am told, indeed, that this tracery was of a very poor and mean character; and perhaps had I seen it, I might have regretted it less than I do. The loss of the Guesten Hall we all regret; but we cannot justly blame the Dean and Chapter, who, although at the time engaged on the costly work of the Cathedral, offered to find £5,000, one-half of the estimated expense needed for the Guesten Hall, if those who desired its preservation would raise the rest—and received one promise of £5 towards it. But may not both systems, both restoration and preservation of ancient buildings, be objected to from another point of view? Are not both alike the result—may not both alike be in some

degree the cause—of a great want of originality in the present day? Who can imagine either the one or the other in the times of our great architects, whether we take William of Sens, or William of Wykham, or Christopher Wren? It was not in every case a Danish robber, or accidental fire, or bad foundation that destroyed our fine early churches. Scarcely was the Norman and semi-Norman Cathedral of Worcester—begun in 1084—completed and consecrated in 1218, when the Bishop laid the first stone of the Early English choir and chapels (1224). Plenty of money was coming in; and so it was at once resolved to make the building much larger and much more beautiful, as they considered it. They did not think the stonework so valuable that it must be preserved at any cost. Later on we do indeed find the men of the 15th century proud of their noble Norman chapter-house, and carefully and skilfully preserving it from the danger it then was in of becoming a ruin. But still they worked freely in their own fashion. They tried to save its walls, so they put into them what we call Perpendicular windows. They added buttresses outside—buttresses in the Perpendicular style. They left traces of the Norman, perhaps from antiquarian motives, more probably to save trouble; but they did not hesitate to put in a Perpendicular doorway. All this they did as a matter of course. It was their way of building. What is ours? Have we any style at all? If what we build now lasts 500 years, will there be anything in it to tell in what century it was built? This want of originality may be partly the effect—perhaps also partly the cause, of our treatment of ancient buildings—whether we treat them after the fashion which began some forty or fifty years since, "restoring" them as far as we can to the designs of their original builders; or, according to the new plan, of "preserving" every scrap of work older than ourselves, without thinking much of the present use or object of the building. Such careful and minute study of old work seems likely to check any freshness of artistic thought. It is quite true that in the period of the Renaissance the artists and architects did most carefully study and copy the works of the Romans; but they were using them for new purposes. But the extraordinarily rapid deterioration of this style seems to show that it was not based on sound principles. The copying of the ancient forms and ancient decorations seems to have had, not immediately, but ultimately, the effect of destroying style altogether. And now we have again taken to this copying; and I fear the result will be even worse than before. Men of artistic taste will now, as ever, design and erect buildings true and beautiful. And is there no remedy, no hope of improvement? I see none. Some of the elements of advance in architecture, considered as a fine art, undoubtedly are present. New materials, or at least new methods of treating the old materials—iron and other metals, glass, artificial stone—ought to give rise to something beyond the past. There is also a fair demand for new buildings; and not a few men of ability, of good artistic taste, embrace the profession of architect. But all this has been true for the last fifty years; and nothing has come from it which may be considered as characteristic of the present day. I am aware that even if the practical effects archaeological studies have had upon our architecture are to blame in some measure for its want of originality, they are not the only cause of it. For a long time "perfection of workmanship," in the sense of neatness and finish, combined with cheapness, has been the object of Englishmen, beauty being left out of the question, or looked upon as an occasional extra; and the natural result has been to throw much of our energy into the form of engineering, rather than into the fine art of architecture. Still I think archaeology is partly to blame. But we cannot help it. The study—for I will not call it a science—the study our association is devoted to is far too interesting, far too valuable to be checked by the thought that in some ways it may do, or may have done, mischief. I suppose we must of us pursue it simply for its own sake. But if asked what use it is of, we may fairly answer that it is the hand-maid of history; that it helps us to fill up the outlines given us by the chroniclers of old times; that further back it is the only source of such historical knowledge as we possess; and that it is by its means that we may perhaps hope eventually to solve the great questions of the

unity (or non-unity) of the human race, of the original condition of man in respect of what, for shortness, we express by the words civilisation and morality.

The members then proceeded to the *Priory Church*, where Mr. W. Jeffrey Hopkins, F.R.I.B.A., of Worcester, read a paper. The Abbey of Malvern was, he remarked, founded in the 11th century, according to Dovecot in 1085, but there had previously been an oratory of St. Werstan, at the place near St. Anne's Well, still known as the Hermitage, and where bones, coffin-lids, and other proofs of interment have been dug up. Of this St. Werstan, to whom the Priory as well as the oratory was dedicated, we knew little except that he fled from Deerhurst to Malvern in the time of Edward the Confessor, and was martyred here about 1056. No mention of Werstan existed in the Calendar, and the only record of him was the miracles depicted on the shattered glass of a much more recent date, still to be seen in this church. The earliest part of the structure around them was built by Prior Alwyne, a monk, who had served under Wulstan, of Worcester. Alwyne founded this, with the aid of thirty monks of the Benedictine order, to which belonged the great neighbouring abbeys of Worcester, Pershore, Tewkesbury, and Gloucester. There were grounds for believing this priory church, like all the others just mentioned, had a double apsidal eastern termination—a very rare feature in England, and probably imported from the banks of the Loire. The clerk of works engaged in the restoration of Malvern Priory under Sir Gilbert Scott, found that although the eastern end was now square, there were foundations of a semicircular aisle prolonged into an apse, and Mr. Nott and others now present had seen these remains. Beneath the chancel were remains of a crypt, and it was a singular coincidence that all the Norman towers erected over the crossings of great abbey churches, with crypts to the east of them, fell at about the same time from the failure of the range of columns, in each case crushing the eastern part of church. Winchester tower fell in 1079, Worcester in 1084, Gloucester in 1080, and Canterbury in 1096, while this one also failed about that time, and at the present time they could see the tower piers leaned to the east, especially on the north side. Mr. Hopkins asked the audience to look around them and picture the great Norman church as it appeared when completed eight centuries ago. The great circular piers and arcading of the nave and aisles still remained, but there was then no lofty clerestory as at present, but a low roof; the tower piers, although recessed, and the transepts—the southern one—largely restored, yet existed, and also the outline of the eastern portion except its apse. The walls were not bare as now, but covered with distemper paintings. Yet while the Norman fabric could be reconstructed internally with little difficulty, a hasty observer would say that the exterior was entirely Perpendicular, except the Norman door on south side of nave. They might notice that the western portion of nave was of a slightly later date than the three eastern ones; the piers, instead of having a plain chamfer, had sub-bases and bases composed of a torus and hollow moulding. One or two traces of Early English existed in the capitals at the crypt entrance, below the east window, and of the Decorated period there were worked into the same blank arch a series of bosses, still gilded in places, and probably removed from groined roof of the former Lady-chapel, and the tiled floor might still be seen projecting from the east end, but the remains of this period were poor in character. Coming to the Perpendicular period, they saw extensive works excellent in their style, and the dates 1453 to 1456 on the tiles set in the east wall above altar, and the fact that the high altar and six other altars were reconsecrated in 1460, gave a very probable period of completion. The soffits of the great lower arches on Norman piers showed great judgment and skill in the architect who altered them, but the same could not be said of the great nave clerestory lights, and he was inclined to think another man must have carried them out, from the unsightly interval of bare walling left between the arcade and clerestory—possibly intended to be decorated with paintings. In the choir they saw vaulting piers and springers carried up to receive groining never added except in wood. At the back of altar, between it and east window, was a

singular raised passage, semicircular in form, and with the wall pierced by four deeply-splayed squints, two of which looked into the former Lady-chapel, and the others into the north and south aisle eastern chapels. The glass in this church was not excelled anywhere in England in its skilful arrangement of cusped panelling and disposition of lights in connection with blank panelling, especially in the west window of the south chapel. The fragments of many windows were, however, jumbled together, and although it might be best to let them be, he would suggest that they might be restored if careful tracings or drawing in colours were made of every light, and the copies then cut up into subjects, and sorted like a child's puzzle until the corresponding pieces were properly rearranged. Of the abbey buildings, which all lay to the south, few traces remained. The line of the cloister-roof could be seen on south side of nave; the priory-gate, occupying a corresponding position to that at Bristol, still existed, and so recently as 1841 the beautiful refectory, which had long been used as a barn, was wantonly destroyed by a builder; drawings of the roof were now on view at the College Hall. This church was that of the priory, not the old parochial one, which was dedicated to St. Thomas, and measured about 92 ft. by 36 ft.; a few remains existed. This priory church was bought soon after the Dissolution for a parish-church, and in 1788 it was reported ruinous—the result of wanton folly, ignorance, and neglect. Boys were allowed to use the windows as targets; the roofs went to decay; the parson used a portion of the fabric as a dovecot, and the room over the great north porch was a servants' hall. In 1812 the fabric was partially repaired, and again in 1815, and recently it had been thoroughly restored by the late Sir Gilbert Scott.

Mr. E. P. Loftus Brock, F.S.A., added a few architectural explanations, remarking that an apsidal plan for an eastern end was not so rare in early churches as Mr. Hopkins had supposed, and was common to all churches having a Roman origin; thus, in the little church of St. Pancrace, Canterbury, of the time of the Roman occupation, just unearthed, they found this plan. It was interesting to note that in Malvern, Tewkesbury, Gloucester, and other Norman buildings of this district, the capitals, like the piers, were circular, and not square or octagonal—a mode of construction not introduced into the east, south, or north of England till the 13th century. Thereconsecration, in 1239 at Malvern, Tewkesbury, Pershore, &c., was not necessarily due to structural alterations, but was in obedience to an order from the Pope's legate in London that all churches which had been rebuilt within the past century or two should be reconsecrated.

A hurried perambulation of the building was then made, the grotesquely-carved misereres under the stalls (which have been picked out in chocolate colour upon the naturally-blackened oak ground), the dated tiles in choir, the passage behind altar, the alabaster altar-tombs to John Knottesford, his wife, and daughter, and the confused stories in the stained glass receiving most attention within, while outside the traces of conventual adjuncts on the south side, and the re-settings of Decorated fragments in the east wall, provoked some discussion.

In the evening the members dined together at the Imperial Hotel, under the presidency of the Dean.

TUESDAY.

The day's excursion, begun and ended by a railway journey, included visits by carriage to several village churches of Early character, and to Tewkesbury Abbey, and in the evening, at the first meeting for the reading of papers, on account of the heavy showers in the morning, the programme had to be curtailed.

RIPPLE,

the first village visited, still possesses on the green the shaft and base of the cross, raised upon a modern pedestal of three stages of brick and stone; the shaft is of oolite stone, and the head, now missing, is supposed, from a similar example removed from the adjacent village of Upton, to have been of iron. Close by are the parish stocks, still in good condition. The Church is a cruciform building with lofty transepts, and large central tower, finished by an Italian balustrade between the Decorated pinnacles. The church is chiefly of Early English

character, having arcades carried by piers of four-clustered circular shafts, with scalloped caps of semi-Norman character. In the chancel is Late plate tracery to the windows, and a series of misereres, carved with spirited representations of peasants dressed in smocks, engaged in harrowing, reaping (one with a scythe), sowing, driving a pig, sheep-tending, &c.; they are larger than the stalls, above which they are inappropriately nailed to the walls, and are supposed to have been brought from some large church—tradition says Worcester. Beyond these stalls the chancel is quite bare, and some faded Christmas decorations on the pulpit and across chancel-arch attracted some attention. The rector, the Rev. R. Holmes, read a paper giving the history of the church and the adjacent monastery, which existed in Saxon times, and of which a few remains exist at the rectory. The church was restored 20 years since, when a beautiful thurifer, of beaten copper, was found at the east end. This, Mr. L. Brock pronounced to be an excellent example of Middle 14th-century period; it has on the cover a model of a cruciform church, pierced by holes for the hanging chains. In the south transept arch the rector showed a Bible, Psalter, and Service, of the closing years of Queen Elizabeth's reign. Having seen the shaft of a second cross in the churchyard, the carriages were resumed, and crossing the Avon at Twining, by chain ferry,

BREDON CHURCH

was seen. This, like the last, is a cruciform edifice, but has a lofty spire upon the tower at the intersection, and contains, as Mr. Brock said, an assemblage of the characteristic features of the churches in this district. The nave is Transitional-Norman, the three entrances being under round-headed arches, and to the south a chapel or quasi-aisle of two bays was thrown out about 1230; the two-light windows have two plates of trefoil cusping, the inner one supported by Purbeck marble shafts. The chancel was rebuilt in the Decorated period, and a little later a second quasi-aisle, with flowing tracery to windows and clustered piers and shallow mouldings to arcade, was thrown out on north of nave. The west window and spire are Perpendicular additions, and in the south chapel, which has a piscina, is a sumptuous mural monument, adorned with obelisks, scrolls, and other Jacobean ornaments; it is to the memory of Giles Reede, A.D. 1611. In this chapel are also three low recesses, two containing floriated stone coffins, and the third a shield, having upon it two forearms and hands bearing a heart. In the south side of chancel are three 14th-century sedilia, and next them, set upright, is a coped tombstone, having upon it a carving of a crucifix, above the arms of the cross being a pair of doves, and the busts in high relief of a man and woman. The risers as well as the treads of the altar-steps are paved with 15th-century tiles, similar in character to those in Malvern Priory, but having armorial bearings. At the foot of the steps is a brass to John Prideaux, Bishop of Worcester, who, after the sequestration of his See, returned to this parish and died here in great poverty. Mr. Brock remarked that during a restoration in 1842 the sedilia was pierced for purposes of ventilation, and as it now resembled a low side window its position might furnish a crux for future archeologists unless the fact were recorded.

The well-known tithe-barn at Bredon was afterwards visited. It much resembles one at Avebury, Wilts, in which this Association dined on one of the Congress days last year, but has outer-walls of stone, and a roof of thin slabs of stone. The interior, some 135 ft. long, is divided into a nave and aisles, with projecting double porches or transepts, by massive timber supports: in each of the nine bays of the main roof a pointed arch supports a collar and curved struts, and is itself tied in by a second collar, and the aisle-bays are also of single-pointed arches with cross-ties in the transverse section. On the north side is an upper chamber, having a good octagonal stone chimney, with pyramidal cover, supported by little shafts. The immense original key is still preserved, and has double wards on either side. The barn is a highly interesting and at present singularly perfect specimen of the larger kind built about 1450, but the roof admits the rain in several places, and requires the proverbial "stitch in time."

OVERBURY CHURCH

was next inspected. Here was a third cruciform structure, in this case with a central tower of Perpendicular character, having a richly carved and perforated stone belfry. Inside, the original Transitional Norman aisles to nave have been replaced by wider ones of modern Decorated type, so that the deeply-splayed Norman clerestories now open on their outer faces into the aisles. The piers are circular and very low, the caps being square, with deep chamferings; on the nave faces are label mouldings, that on south side being broken up by a double wave-ornament. The west end has a good Early English transept, and the chancel windows are good specimens of Early English work. The rector, the Rev. Chas. Glynn, stated that the church had just been restored by Mr. R. Norman Shaw, R.A., to whom was due the stone groined roof which now covered the chancel. Considerable discussion took place with reference to the font, which has a tapering cylindrical bowl (on a 14th-century base), rudely carved in high relief. Some local sculptor has restored it in ludicrous fashion in cement, the missing side of a bishop being reproduced with a second staff in right hand. Several contended that this bowl was coeval with the present church—and of 11th century—but others held that it was as early as the Confessor's date, and called attention to the model of Christ held in the hand of a priest's figure, and the costume, as corroborative of this opinion. Prebendary Ingram contended it was Danish in origin. At

TEWKESBURY

the Abbey was visited after luncheon, the members being received by the vicar, the Rev. Hemming Robeson, M.A., for whom an elaborate descriptive paper was read by Mr. J. R. Sergeant. At the conclusion of the paper Sir J. Allanson Picton, F.S.A., proposed a vote of thanks to the author and reader, remarking that the manner in which this noble abbey church had been restored reflected high credit on all concerned in the work. The Abbey was so fully described on the occasion of the Architectural Association's visit, in the BUILDING NEWS of the 12th inst., when the south-east front of the Abbey was illustrated from a new drawing, that it will now be sufficient to refer to that issue. The members, having divided into sections and inspected the whole of the interior of the Abbey, visited the 17th-century bowling-green attached to an inn, which is surrounded by old yews, and some of the picturesque half-timbered houses in the town.

In the evening a meeting was held in the council-room of Malvern College, under the chairmanship of Rev. Prebendary Smith, Vicar of Malvern. Mr. J. Tom Burgess, F.S.A., of Worcester, delivered an address on—

"THE ANCIENT ENCAMPMENTS OF THE MALVERNS,"

illustrated by a series of plans and sections, drawn by Mr. H. H. Lines, of Worcester. Having first shown the direction of the lines of fort drawn, as Tacitus tells us, in an oblique direction across England, along the banks of the rivers Nene, Avon, and Severn, by the Roman general Ostorius, Mr. Burgess said that the bold range of hills below which the Congress was being held, marked the disputed boundary-line where the Belgic wave ceased and the Celtic began. Every crest and hill in the line of the Malverns, from the Bristol Channel to the banks of the Dee, was still crowned by the earthworks and encampments used by the Silures and Ordovices, the two kinds being distinct from each other in their traces at the present day. Those in the immediate neighbourhood he presumed to be Silurian defences, and when these were formed the fertile cultivated plains now at the eastern foot of the Malverns were marshy districts, often flooded, and the outcropping hills were then easily-defended islands. The entrenchments at Meon Hill, on the opposite side of the eastern plains covered some 30 acres, and in them had been found Roman javelins, now distributed in the Warwick, Worcester, and Sir Henry Dryden's collections, while close by was a tumulus which had yielded undoubtedly British remains. The hill seemed to have been held alternately by the opposing forces. On Bredon hill, still nearer, was a camp of somewhat different character, and a third island in the plain of Evesham, Elmby, contained also the Medieval earthworks

thrown up by the Beauchamps. Two years since he aided in carrying out excavations, with Mr. F. G. Hilton Price, F.G.S., at the great remains on the Herefordshire Beacon. The fortified area involved the whole summit of this great hill and the adjacent one of Midsummer, and consisted of an oval deep ditch, with rampart round it, having a circumference of 6,800 yards, the longest diameter being 932 yards. The ditch was 7ft. deep, and broad enough for one chariot, and there was but one ancient entrance, that to south, although a modern one injured the line at the N.E. point. In the centre was a strongly-fortified citadel, and outside and below this other and larger walled-in spaces. All over the area were pit-like depressions, which appeared to be permanent dwellings, averaging 15ft. by 9ft., and 6ft. deep; outside the citadel, at Hallow-Bush, were walled inclosures, which may have been for cattle-pounds in times of danger, and others for sheep; and within the protected area was "St. Anne's well," as it was now termed. Amongst the remains found were many specimens of red pottery of the 15th and 16th centuries, some dated, and below these, flint flakes, bone stones, iron tiles, a bronze ferrule, broken bones of the pig and other domestic animals—enough to prove the continued occupation and use of these dwellings. The so-called Druids' sacrificial stone appeared to be a boulder, removed by natural means to its present site, and the traditional earthen Druids' seats were but rabbits' burrows, which had occasioned several of the minor irregularities of the surface. Mr. Brock read a letter upon this chain of events, written by Mr. M. H. Bloxam, who was unable to be present through ill health, and added that it was to the patient investigations of Mr. Rouch-Smith, Mr. Price, Mr. Burges, and others, that archaeologists had been able to establish that these earthworks were no mere summer encampments hastily thrown up and abandoned, but the permanent dwelling-places of races of people, who dwelt in pits on the hill-tops, and kept flocks and herds, folding them on the sides of the hills when danger threatened. Mr. G. R. Wright, hon. congress secretary, referred to the hardship and waste of archaeological spoils occasioned by the existing barbarous law of treasure-trove; and Mr. Burges, in his reply, said that he had been a victim of this absurd law of Edward III.'s time, for the silver and gold ornaments found in a Saxon lady's grave were seized by the Treasury authorities, who paid 25s. compensation for value of metal, not to the explorer, nor to the owner of the soil, but to the labourer who actually dug them up, and then sold them to the British Museum trustees for ten guineas. Such injustice led, as Mr. Wright had said, to the melting up of priceless antiquities by the finders.

THE GLASS IN MALVERN PRIORY CHURCH.

Mr. John Nott, of Malvern, read a paper upon this subject. Fifteen windows of the church still, he said, contained portions of the old painted glass, which was of three distinct periods—fourteenth century, middle of fifteenth century, and beginning of sixteenth century. The oldest was that in the south chapel, that of St. Anne, the eastern window showing, in graphic manner, the Creation of the World, in nine compartments; the middle window, the history of Noah, and events in Abraham's life; and in the western window showed Our Saviour's Passion; and several other incidents in the Trial and Crucifixion were illustrated in other windows. Of the second or Perpendicular period were the great east and west windows and the north clerestory lights of choir, the latter including the famous series of illustrations of St. Werstan's legends, executed for Prior John of Malvern, who was said to have written the scraps of Latin by which we have identified and interpreted them. These were greatly damaged and confused, many of the pieces having been lost and others transposed. Of the latest period was the great north transept window, the date of which was 1591 or 1595, and which was said to have been given by Henry VII.; it still contained portraits of Prince Arthur and Sir Reginald Bray; but those of Henry VII., his Queen, and the Princess Elizabeth, although known from descriptions to have existed, had quite disappeared. A short discussion followed, in which the chairman, Mr. J. Cope, Colchester, Mr. Brock, Mr. G. R. Wright, Rev. — Taylor, and others took part, the foreign or English origin of the painters of much of our mediæval stained

glass being warmly disputed. The former theory had, in many cases, tradition to support it, but it was stated that the alleged Flemish woodwork, works of Dutch artists, and Italian sculpture, had often been shown to be purely native workmanship, and that the same thing was probably true of glass.

WEDNESDAY.

Of this day's excursion the ancient town of Ledbury made the centre, several of the neighbouring village-churches being visited by carriage from it. Leaving Malvern by special train, a party of about eighty members left Ledbury at 10 a.m. by carriages for *Bosbury*. The church is remarkable for a massive detached square tower standing some 180ft. to the south of the church, much resembling that at West Walton, North Norfolk, visited by the Association in 1878. The church is chiefly of Transitional Norman character, with a Tudor chapel with fan tracery at east end of south aisle. The rood-screen still retains its position, and is Late 15th-century in style, with fan coying above the open work supporting a heavy cornice. The pulpit contains four carved panels representing the Adoration; Flight into Egypt; Crucifixion and Resurrection of our Lord; these are said to have been brought from Flanders. The font in use is square, with shallow bowl supported on five columns, the whole being of a local conglomerate, and about 1230. At the west end of church is a second font, dug up near, of much earlier character, rudely sculptured. The vicar, the Rev. S. Bentley, read an exhaustive paper in the church, in which he mentioned that the tower was one of seven detached ones existing in Herefordshire, and from its narrow windows and thick walls seemed to have been used as a place of refuge.

In the churchyard is a perfect specimen of a cross, of red sandstone, 12ft. high, and an oaken lych-gate. The vicar afterwards showed the remains of the palace of the Bishops of Hereford, now part of a farmhouse, which has just come back into the possession of the bishops. The only original portion is a panelled room, crossed by heavy beams. Near by, in the out-buildings, is the 14th-century gate-house described by Mr. J. H. Parker in his "Domestic Gothic Architecture." The outer face is of stone, and the inner one has two large oak beams carried the whole height of structure as an ogee arch, and filled in with masonry. The Crown Inn, formerly the residence of the Harford family (two of whose Elizabethan monuments had been seen in the chancel of church) was next seen. The principal room has oak panelling surrounding the wall, and at the intersections of beams in ceiling and over the fireplace are oak shields, carved in relief with armorial bearings. Some other houses and foundations on site of Knights Templars' house were seen, and the party returned to *Ledbury*, where the Market House and Church* were seen, the members peeping into one of the picturesque 17th-century half-timbered cottages which line the Church-lane, to find that the beautiful oak carvings on the walls had been concealed by cheap coloured religious and sporting prints. At the parish-church, a very large and lofty edifice kept in admirable repair, but still retaining low pews, the vicar, the Rev. John Jackson, read a descriptive paper upon its architecture, which he showed included specimens of every style from Middle Norman to Tudor, while the upper part of tower and spire was added to the detached steeple about 120 years since, and the ceilings to north aisle and the chancel were put up a century ago. A few years since, the church was restored under the direction of Mr. Allen, of Hereford. Mr. Loftus Brock followed, remarking that the church seemed to have been a model and architectural school for the district, noting that the narrow proportions, the great height of windows, the simple mouldings, the ball-flower ornamentation, and other features of many periods were to be found repeated in the neighbouring village churches. He also referred to the peculiar form of the chancel arch, which was beginning to fail from want of abutment on the south side, and suggested that early attention should be given to it. Sir Charles Boughton was glad that the vicar had shown himself so fully alive to the beauties and requirements of the fabric in which he served. Col. Bramble explained the

* Illustrated from measured drawings by Mr. E. J. May in the *Building News* for Dec. 14, 1877.

upright effigy on the south wall of St. Catherine's Chapel as that of a priest of the 13th century.

After luncheon at the Feathers Hotel, carriages were resumed to *Much Marele Church*, which, with its alabaster monuments, was described by Mr. G. H. Piper, F.G.S., of Malvern, Hellen's House, the seat of Mr. R. D. Cooke, being visited *en route*. Kempley Church, where a number of interesting mediæval frescoes still exist in good condition, was shown by the rector, the Rev. J. Crowley Weaver; and the members, after seeing Preston Court, the residence of Mr. W. Hardland, returned to *Ledbury*. Malvern was reached by special train soon after 7 p.m., and in the evening a crowded meeting was held at Malvern College, when papers were read on "The Ecclesiastical State of the Diocese of Worcester During the Episcopate of John Carpenter—1444-76," by the Rev. Canon Winnington Ingram; and on "The Antiquity of the Game of Golf," by Mr. Chas. F. Compton, of London.

THURSDAY.

Yesterday (Thursday) the members were to drive from Malvern by road through *Castle-Morton* to *Birt's-Morton Court*, a fine specimen of the moated house of the 14th century, and the adjoining erections, and thence to *Payne's-place*, where Margaret of Anjou took shelter after the battle of Tewkesbury. After luncheon at the *Mess House*, the party were to proceed to *Upton-on-Severn*, and to *Severn End Manor House*, returning through *Blackmore-park* to *Malvern*.

Friday's (to-day's) programme is devoted to visits to *Kidderminster*, *Bewdley*, and *Stourport*; that of Saturday to *Little Malvern Church* and *Council House*, the encampments on the *Herefordshire Beacon* and *Midsummer-hill*, and the Norman stronghold *Branshill Castle*, and a specimen of the modern antique at *Eastnor Castle*. Three extra days are arranged for next week: Monday and part of Tuesday to be spent at *Worcester*, and Wednesday to *Cheltenham* and *Thirlestane House*. We shall continue our report next week.

WIND-PRESSURE ON RAILWAY STRUCTURES.

THE following is the report of the Committee on July 29, 1880, to consider the question of wind-pressure on railway structures. It is published in a Blue-book, with appendix and diagrams:—

"To the Right Honourable the President of the Board of Trade.

"London, May 20, 1881.

"Sir,—In compliance with the instructions from the Board of Trade (a copy of which is given in the appendix) to consider the question of wind-pressure on railway structures, and to report to them on the subject, we have made such inquiries and procured such information on the subject referred to us as we deemed necessary, and have now the honour to report the conclusions at which we have arrived.

"It was necessary in the first instance to ascertain as accurately as possible from the sources which were accessible to us what the highest pressures of the wind in this country amount to. With this object we obtained from those observatories and stations where the pressure or velocity of the wind is measured the statements which we give in the appendix. In order to exhibit the action of the wind during heavy storms, we have also appended lithographed copies of wind-diagrams taken by means of self-registering apparatus at *Bidston*, *Glasgow*, and *Greenwich*. At some of the stations from which we have obtained returns the wind-pressures are measured directly by Osler's self-registering pressure anemometers, at others the velocity only of the wind is measured by Robinson's rotating anemometers, the velocity of the wind being taken at three times the velocity of the revolving cups. For some stations the only published information is the run in miles of the wind during each hour. There can obviously be no more than a general accordance between this and the greatest pressure experienced during the hour. To utilise for our purpose observations taken at stations where the velocity only of the wind is recorded the records

of the Bilston Observatory, where both elements are recorded, have been employed as furnishing a means of connection between the two. In the case of high winds, with which alone we have to deal, it was found that the greatest pressure recorded in an hour was tolerably well-proportional to the square of the mean velocity during the hour, and that the empirical formula $V^2 \cdot 100 = P$, where $V = \text{maximum run in miles of the wind in any one hour}$ and $P = \text{maximum pressure in pounds on the square foot at any time during the storm to which } V \text{ refers,}$ represented very fairly the greatest pressure as deduced from the mean velocity for an hour. We have accordingly given in the appendix a table calculated from the above formula for deducing *maximum* pressures from observed velocities. In addition to the tables obtained from English, Irish, and Scottish stations, with are those only that are strictly applicable to our inquiry, we give as matter of information a summary of strong winds registered at stations on the Continent and in India.

"It will be seen, on reference to the tables, that the wind-pressures vary greatly at different stations. This, no doubt, mainly arises from difference of exposure of the stations to the action of the wind, in consequence of the geographical and local circumstances of their position, but may in some cases be partly caused by differences in the instruments used for measurement. Thus, at Glasgow, the highest recorded pressure per square foot is 47lb., while at Bidston, near Liverpool, the indicated pressure on one occasion amounted to 90lb., and on another occasion to 80lb. But the pressures at Bidston seem very abnormal, being much beyond what have been noticed at any of the other stations. The conformation of the ground on which the Bidston Observatory stands is such that the velocity of the wind there might be greatly intensified. It will be noticed in the lithographs that the records of exceptionally high pressures indicate a very brief duration. From inquiries we have made we are satisfied that these records are not referable to instrumental error, depending on the recording instrument being carried by its momentum beyond the position of equilibrium under the wind-pressure acting at the moment, but represent a real phenomenon. But whether the exceptionally high velocities to which such pressures are due extend over a considerable space in a lateral direction, or, on the other hand, are extremely local, is a point on which we have not been able to find experimental evidence.

"The differences of the wind-pressures observed at different stations lead us to consider whether there were any other modes of approximately ascertaining the force of the wind for our purpose. There are many buildings, tall chimneys, ship-building sheds, &c., which probably would not withstand pressures so extreme as those we refer to; but in most cases the contour of the adjoining ground, and the obstruction to wind by adjoining buildings, trees, and other surrounding objects, would render conclusions drawn from such cases unreliable. It occurred, however, to us that some useful information might be drawn from another source—viz., from railways themselves. It is obvious that on existing railways that have been long in use a series of experiments, if we may apply such an expression to them, have for many years been carried on, for over them trains have been running at all times of the day and night on high and unsheltered embankments and along other spaces exposed in many cases to very strong winds. Now, a wind-pressure varying from 30lb. to 40lb. per square foot is sufficient to overturn the ordinary railway-carriages that have been in use during the last 25 or 30 years, and we thought it useful to inquire from the different railway-companies for cases where railway-carriages have been overturned by the force of the wind. The only cases of this kind that have been brought to our knowledge are appended to this report.

"From the information thus acquired, from the inquiries we have made, and from the consideration we have given to the subject, we are of opinion that the following rules will sufficiently meet the cases referred to us:—

"(1) That for railway-bridges and viaducts a *maximum* wind pressure of 56lb. per square foot should be assumed for the purpose of calculation.

"(2) That where the bridge or viaduct is formed of close girders, and the tops of such girders are as high or higher than the top of

a train passing over the bridge, the total wind pressure upon such bridge or viaduct should be ascertained by applying the full pressure of 56lb. per square foot to the entire vertical surface of one main girder, only. But if the top of a train passing over the bridge is higher than the tops of the main girders, the total wind-pressure upon such bridge or viaduct should be ascertained by applying the full pressure of 56lb. per square foot to the entire vertical surface from the bottom of the main girders to the top of the train passing over the bridge.

"(3) That where the bridge or viaduct is of the lattice form, or of open construction, the wind-pressure upon the outer or windward girder should be ascertained by applying the full pressure of 56lb. per square foot, as if the girder were a close girder, from the level of the rails to the top of a train passing over such bridge or viaduct, and by applying, in addition, the full pressure of 56lb. per square foot at the ascertained vertical area of surface of the ironwork of the same girder situated below the level of the rails, or above the top of a train passing over such bridge or viaduct. The wind-pressure upon the inner or leeward girder or girders should be ascertained by applying a pressure per square foot to the ascertained vertical area of surface of the ironwork of one girder only, situated below the level of the rails or above the top of a train passing over the said bridge or viaduct, according to the following scale, viz:—

"(a) If the surface area of the open spaces does not exceed two-thirds of the whole area included within the outline of the girder, the pressure should be taken at 28lb. per square foot; (b) if the surface area of the open spaces lie between two-thirds and three-fourths of the whole area included within the outline of the girder, the pressure should be taken at 42lb. per square foot; (c) if the surface area of the open spaces be greater than three-fourths of the whole area included within the outline of the girder, the pressure should be taken at the full pressure of 56lb. per square foot.

"(4) That the pressure upon arches and the piers of bridges and viaducts should be ascertained as nearly as possible in conformity with the rules above stated.

"(5) That in order to insure a proper margin of safety for bridges and viaducts in respect of the strains caused by wind-pressure, they should be made of sufficient strength to withstand a strain of four times the amount due to the pressure calculated by the foregoing rules. And that, for cases where the tendency of the wind to overturn structures is counteracted by gravity alone, a factor of safety of two will be sufficient.

"With regard to the eighth paragraph of the report of the Select Committee on the North British Railway (Tay-bridge) Bill, to which you have drawn our attention, we beg to observe that where trains run between girders they will generally be sufficiently protected from the wind, the degree of protection afforded by the girders depending on the extent to which the girders are open or close; where the girders are so open as to afford insufficient protection, or where trains run, as in some cases they may do, on the tops of girders, we assume that the engineer will provide a sufficient parapet; but we are indisposed to go further into detail on this subject, as it might tend to stereotype modes of construction, which we think is undesirable.

"In conclusion, we beg to point out that the velocity of wind, like that of every other moving body, is more or less retarded by friction, and will be affected, therefore, by the character of the surfaces over which it has to pass, which may be rough, smooth, or irregular. It will follow, therefore, that, other things being the same, greater velocities will be attained at higher altitudes than at low ones, the wind at higher altitudes being further removed from retardation by friction. Though we are of opinion that no bridge or viaduct is likely to be built in such a situation as to expose it to wind-pressures equal to those which have been occasionally indicated by the disc on the Bidston Observatory, yet, even if that were possible, a bridge or viaduct constructed according to the rules we have given would not be subjected to strains nearly equal to its theoretical strength. On the other hand, there will be many structures of small altitude or in sheltered situations which never can be exposed to the wind-pressure we have assumed, and where the application of the rules we have given would require modification.

Some modification of the rules may also be required in the case of suspension or other bridges of very large span, but such cases will be of rare occurrence, and we recommend that they should be specially considered when they arise.

"We have the honour to be, Sir, your most obedient servant.

"JOHN HAWESHAU,
"W. G. ARMSTRONG,
"W. H. BARLOW,
"G. G. STOKES,
"W. YOLLAND.

"We, the undersigned, concur in the above report so far as it goes, but we think the following clause should be added—viz.:—

"The evidence before us does not enable us to judge as to the lateral extent of the extremely high pressures occasionally recorded by anemometers, and we think it desirable that experiments should be made to determine this question. If the lateral extent of exceptionally heavy gusts should prove to be very small, it would become a question whether some relaxation might not be permitted in the requirements of this report.

"W. G. ARMSTRONG.
"G. G. STOKES."

A NOVELTY IN RAILWAY-CONSTRUCTION.

THE Darjeeling Tramway or Himalayan Railway is a novelty in railway construction, and will be justly regarded as one of the engineering sights of India. In his speech at the opening Sir Ashley Eden claimed for the enterprise the merit of having "solved problems never before solved in the history of railway undertakings." "We know," he said "of no other line which ascends 7,400ft. in 50 miles, mounts gradients of 1 in 21, and comes round curves of 70ft. radius." The line is described as presenting to the eye the appearance of "a snake winding up into the clouds." The tramway, which is 50 miles long, enables the journey from Calcutta—361 miles—to be performed in about 24 hours. Its terminus at Darjeeling is 7,690ft. above the level of the sea. The capital of the Darjeeling Tramway Company is stated to have been raised entirely in India. The line was originally to have been completed within 18 months, but this period has been exceeded. The first rail was laid in May, 1879, and the contractors, Messrs. Mitchell Ramsay, succeeded in laying down the last between Jore Bungalow (7,800ft. of elevation) and Darjeeling (about 7,400ft.) in June last. The gauge is 2ft. The rails are manufactured of toughened steel, and about 24,000 have been used in the construction of the entire line. Sleepers are laid at intervals of 2ft. 6in., extra sleepers being laid below the rail-joints; altogether above 100,000 sleepers have been used up. Bearing plates have been placed under the outer rails of all curves of 120ft. radius and under, so as to preserve the rigidity of the outer rails. Taking the entire ascent, which commences at about the ninth mile from Silliguri beyond Lukna, at the edge of the Terai, the ruling gradient is 1ft. in 25, but in isolated steep places, the gradient is 1 in 20. From the ninth mile the line curves and recrosses the road frequently; as a rule, however, keeping to the in or hill-side of the roadway. The first distinct deviation from the ascending road occurs at a place locally known as either the Horse Shoe, the Trestle Bridge, or as Agony Point, where the line simply beetles over the edge of the *khud*, and where the trains for safety's sake slacken speed. Above Tendoria, at the nineteenth mile, the train passes through a narrow bridge and slowly describes a loop of some 640ft. in length and then recrosses the same bridge. From the loop onward the line gradually ascends, bearing away to the right, with the *khud* below to the right of the train; while on the left rises a crumbling steep hill-side, looking very threatening, with enormous boulders of disintegrated rock, some of which have already given much trouble to the line-watchers and authorities of the company. The line doubles to the leftward near Mahanuddy and its tea-garden, and then runs parallel, but in the reverse direction, above the road which the train has just traversed. The ascent continues gradually to Kurseong, some 5,200ft. above the sea, and thence onward past some

very troublesome and equally unsafe hill-sides towards Sonada. Thence on to Jore Bungalow. From Jore Bungalow the line descends from the saddle, circling round with deviations towards Darjeeling proper, which is reached in about seven hours, run through from Silliguri, provided no landslips or other obstacles bar the way. The engines at present used are tiny tank ones, the carriages like open tramcars of the roughest and most uncomfortable description. As regards the engines, they are just like ordinary level-line locomotives trusting in the descent to very powerful brakes.

THE ARCHITECTURAL ASSOCIATION AT WORCESTER.—III.

THE Abbey Church of the Holy Cross at Pershore was the first building visited by the Architectural Association excursion party on Wednesday, the 17th inst., when Mr. Aston Webb, in a few words, pointed out the several features and historical points of interest. The plan, which we give herewith, shows by the

on the site of the south transeptal Norman chapel is also gone. The present chancel apse is a very shocking specimen of modern building, the windows being about the most unhappily proportioned lancet windows we have ever seen. Sir Gilbert Scott's work in restoring the choir and tower is in every way conservative and good. The clearing away the ceiling in the Tower, and showing there the beautiful interior arcade and lantern, is a great improvement, though the curious diagonal-placed ringing-stage looks hardly in keeping. The tower-roof is an old one. The decoration at the west-end of the church is a good sample of Messrs. Clayton and Bell's work, and the choir-stalls were designed by Sir Gilbert Scott. The parish-church of St. Andrew's, hard by the Abbey building, is a quaint though sadly bewet and wretched structure now, though once evidently the work of a master hand. It was built by the Abbey of Westminster for the use of their Pershore tenants, in consequence of the feud between the two houses. Now that the Abbey Church is used for the Pershore parish, St. Andrew's is, in one sense, not wanted, the charity funds and other sums

illustrated the week before last. Norton Manor has a well-designed entrance gateway in stone, like the house, with delicate cornices and strings, and the main structure contains two or three very good examples of grouping. The adjoining barn and buildings complete a thoroughly Old English picture, backed as they are by the well-wooded slopes of Wolves or Woollers-hill. Unfortunately, the rain, which had gradually become more continuous, now came down in drenching style, and lasted throughout the remainder of the day. The visit, therefore, to the almost unique old timber church at Besford was much delayed, and sketching there was quite out of the question. The church consists of nave and chancel, south porch, and vestry. The main structure is entirely of wood construction, and in the restoration last year, Mr. Hopkins, the architect, has shown great skill. Every care was taken to replace all the timbers in their original position, and the interspaces have had the modern plasterwork removed, and enriched with plaster diapers, similar to those on Besford Court-house, and this work was executed by one man, and is very admirably carried out. The interior is a great success excepting the new east window, which, though said to be on the line of the old window, is too low for good effect. The richly-carved roof-loft has been lifted up somewhat and repaired, the old carvings being refixed and made good where wanting. The pulpit and lectern, like the nave-pewing, are new, the old high-pannelled pews being now used as a dado to the nave, with good effect. The old triptych is carefully preserved at the end of the Harewell monument. We hope soon to illustrate this very interesting church. The only other timbered church now remaining in the county is at Kington, and this building is as yet unrestored. The timber church of St. Lawrence, at Newlands, was taken down by Lord Beauchamp a few years ago, when Mr. Hardwick built the new stone church there. The old timber chancel was, however, rebuilt as a lych-house in connection with the surrounding almshouses and buildings. Besford Court-house was not seen as intended, the rain having delayed the proceedings so considerably. The transeptal tithe-barn was also missed. The Court-house retains the greater part of the ancient building erected in the reign of Henry VIII., but the timbers are now hidden by plaster and rough-cast. The old pewing at the church, now used there for the dado as already described, was taken from the court-house old staircase, which was removed to make room for the new wing of the mansion. The courtyard retains its old character, though in consequence of continued alterations there is not much of architectural importance to be seen there. Thursday's visit opened with a two hours' stay at Huddington Court, of which we give a view to-day from the drawing of the president, Mr. Aston Webb. This house has lately been de-poled of nearly all its interior fittings, which were till very recently in an almost complete state of preservation. They were taken down to be refixed in the proprietor's house elsewhere. Externally the building has been untouched since the days of Elizabeth, and is in every way an admirable specimen of a timber manor-house. It was the old moated manor of the Winters, who, owing to their connections with Gunpowder-plot, in 1606, were obliged to leave this residence, and have not resided here since. To this circumstance no doubt the escape of the house from alterations is due, and the recent removal of its internal woodwork, including the richly-treated chimney-pieces of oak, which bore the date of 1534, is much to be regretted. The building is enriched by the finest stack of elaborately-moulded brick chimneys to be found in the county, and the solid staircase, opposite the entrance, deserves mention. The church stands hard by, and it is certainly in a most abominable condition—dirty, neglect, and weather all actively combining in their work of destruction. That a church in this county should be allowed to remain in such a condition hardly seems credible. The chancel, for instance, is papered with some recent numbers of the *Worcester Chronicle*, and some of the pews are littered with straw like a stable. The responds of the Transeptal Chapel are covered with wet, green slime, and the font is grained with filth, and occupied by cherry-stones and a huge piece of rough rock. Not long ago, the church was rich

blackened-in walls the portion of the building now remaining, the etched-in parts indicating the original distribution of the chapels and length of nave. These were destroyed about the time of the Reformation. No less than six structures, more or less entirely new, have been erected upon the site of the present Abbey building, as may be seen by reference to the history and architectural proofs, which can be tested. The first church was by Oswald, nephew of Ethelred, King of Mercia; another by Egil Wulf; the third was by Odda; the fourth, built about the close of the 11th century. The fifth was of 13th-century date, consisting of the present choir, erected by Abbot Gervaise and his successor, and, lastly, the tower, which is of early 11th-century date, said by Sir Gilbert Scott to have been the work of the architect who designed Salisbury Cathedral spire.

A drawing of the upper stages of the tower, showing Sir Gilbert Scott's new pinnacles, was given in the "Spring Garden Sketch-book" some short time ago, and drawn by Mr. G. Gilbert Scott, M.A. The south transept at Pershore is probably the earliest part remaining, judging from the masonry and mortar-joints, though Mr. Penrose questioned the evidence alluded to. It is, however, to be observed that the chancel-arch at Wyre Piddle, which is considered the only true example of Saxon work, or rather ante-Norman work in the county, corresponds very singularly with the Pershore south transept arcade and masonry in question, and the work is said to be due to Duke Odda, about fifteen years previous to the Conquest. Mr. Fowler contended, at Tewkesbury, that the caps of the nave arcade there, like those seen on the responds of Pershore tower (which latter show what the nave arcade proportions were) were left as intended for carving, but this notion seems hardly to be correct, inasmuch as precisely the same detail is also given to the caps in every exact particular, both here, at Tewkesbury, and at Glaston, as well as in Great Malvern Abbey, the Glaston work being that of Abbot S. Rio, and dedicated in 1109. Comparative plans of Glaston, Tewkesbury, and Pershore are given in a paper published a few years ago by Mr. Hopkins, in the "Associated Architectural Societies' Reports." Nash gives the length of the Norman nave to have been 180ft. The Early English Lady-chapel no longer remains, and the Decorated chapel built

being equally distributed with those of the mother church. In its present condition it is a disgrace; but the question of dealing with such a building is by no means an easy one to treat with, as the one church is now equal to the needs of the parish, while the income from both livings is not sufficient to allow of its being divided. The party were here photographed by Mr. J. L. Robinson, architect, of Dublin, who, throughout the excursion, took views of the buildings visited, in the same notable way that he did last year, about 130 photographs being thus secured. A new wooden lych-gate, of poor design, has just been erected, under the direction of Mr. Woodyer, architect. The Manor House of Pershore, which we illustrated last week, at Broadway, near Gresham, about ten miles from the Abbey itself. The building is now used as cottages. Leaving Pershore by a beautiful drive along the incline of Bredon Hill, the party soon reached the romantic situation occupied by Woollas Hall, the estate once held by Sir Richard de Mueghros, who left a memorial of his piety here by erecting a chapel in the reign of Henry III., and which he dedicated to St. Catherine. No traces of this building remain, though Mr. Thomas Drew, R.H.A., who conducted the excursionists over the present Hall, thought some of the walls might contain part of the chapel referred to. The house contains a beautifully proportioned hall, with its richly-carved Jacobean screen and gallery over, while the double-storied bay at the other end of the apartment gives size and dignity to the whole. The fronts are constructed of stone, and the house is of admirable design, with a good entrance porch, which bears the date of 1611. A chapel was formed in the upper bedrooms, but is now used for the latter purpose. Some very fine lead stackpipes heads remain of rich workmanship. Mr. Hunsford-Flood, the present proprietor, received the party, and a hospitable tea was provided forthwith by his daughters. The house contains some fine old furniture. The drawing-room is at present incongruous with the rest of the house, but we understand that a new wing is likely soon to be added from the designs of Mr. Drew: a view, showing this was exhibited at the last exhibition of the Dublin Academy. Norton Manor House, now used as a farm-residence, is situated, like the last-named building, in the parish of Eckington, the church-tower of which we
